In 1819, Sir William Parry, a British naval officer and explorer, became the first European to reach Melville Island. He was searching for a northwest passage to Asia. The western portion of the island is governed by the Northwest Territories, while the eastern portion is governed by Nunavut. Ian W. D. Dalziel

Membrane is a term used to describe biological structures that cover surfaces and separate spaces in organisms. For example, *cellular membranes* provide the external boundary for cells and divide cells into functional compartments. They serve as barriers to the passage of molecules in and out of cells and between compartments (see **Cell** [Inside a living cell]).

The term *membrane* is also used to describe thin sheets of tissues that cover surfaces or separate spaces in the body. There are three types of these membranes: (1) fibrous, (2) serous, and (3) mucous. They vary in thickness and in the types of cells composing them.

Fibrous membranes are tough and add strength to the parts they cover. They are made up entirely of fibrous connective tissue (see **Tissue** [Animal tissues]). The fibrous membrane that lines the inside of the skull is called *dura mater.* The *periosteum* is a fibrous membrane that covers the bones. The periosteum also serves as an attachment for muscles, and contains the blood vessels and nerves of the bones.

Serous membranes line body cavities that do not open to the outside, such as the thorax and abdomen. They also cover the outside of the digestive organs and support them. Serous membranes secrete a watery fluid that keeps them moist and prevents their sticking to each other or to the organs they touch. A serous membrane lines the *pericardium,* the sac around the heart (see **Heart** [The structure of the heart]). Other serous membranes include the *pleura,* which lines the lung cavities, and the *peritoneum,* which lines the cavity of the abdomen (see **Pleura**). Inflammation of the peritoneum is known as *peritonitis.* A serous membrane called the *synovial membrane* lines the cavities of the joints. It secretes a watery fluid that lubricates the joints and helps them move easily and smoothly. The largest of the synovial cavities is in the knee.

Mucous membranes line organs and passages of the body that open to the outside. A clear, sticky fluid called *mucus* covers mucous membranes (see **Mucus**). Glands just under the membranes produce the mucus. Mucous membranes form the lining of the mouth, throat, alimentary canal, reproductive system, nose, trachea and lungs, the inner surfaces of the eyelids, and the Eustachian tube. Kermit L. Carraway

Memel. See **Klaipėda**.

Memel River. See **Neman River**.

Memling, Hans (1430?-1494), was a Flemish painter. His name is also spelled *Memlinc.* He is known for his religious paintings, especially of the Madonna and Child enthroned with angels, and for his portraits.

Memling's paintings are characterized by a feeling of sweetness and calm. They show religious stories in narrative detail but without startling dramatic action. Memling combined these personal stylistic characteristics with aspects of earlier Northern European art. Memling's most famous paintings are small panels that decorate the Reliquary Shrine of St. Ursula in Bruges, Belgium. Memling was born in Seligenstadt, Germany, but spent most of his life in Bruges. Linda Stone-Ferrier

Memorial Day, also called Decoration Day, is a patriotic holiday in the United States. It is a day to honor Americans who gave their lives for their country. Originally, Memorial Day honored military personnel who died in the Civil War (1861-1865). The holiday now also honors those who died in any war while serving the United States.

Memorial Day is a legal holiday in most states. Most

Northern States and some Southern States observe Memorial Day the last Monday in May. This date was made a federal holiday by a law that became effective in 1971. Most of the Southern States also have their own days for honoring the Confederate dead. Mississippi celebrates the last Monday in April as Confederate Memorial Day. Alabama celebrates on the fourth Monday in April. Georgia observes this holiday on April 26. North Carolina and South Carolina celebrate it on May 10. Virginia observes the holiday on the last Monday in May. Louisiana observes it on June 3, and Tennessee has a holiday called Confederate Decoration Day on that date. Texas celebrates Confederate Heroes Day on January 19.

Observance. On Memorial Day, people place flowers and flags on the graves of military personnel. Many organizations, including Boy Scouts, Girl Scouts, and fraternal groups, march in military parades and take part in special programs. These programs often include the reading of Abraham Lincoln's "Gettysburg Address." Memorials are often dedicated on this day. Military exercises and special programs are held at Gettysburg National Military Park and at the National Cemetery in Arlington, Virginia. In addition, to honor those who died at sea, some United States ports organize ceremonies in which miniature ships filled with flowers are set afloat on the water.

Since the end of World War I, Memorial Day has also been Poppy Day. Volunteers sell small, red artificial poppies in order to help disabled veterans. In recent years, the custom has grown in most families to decorate the graves of loved ones on Memorial Day.

History. Several communities claim to have originated Memorial Day. But in 1966, the U.S. government proclaimed Waterloo, New York, the birthplace of the holiday. The people of Waterloo first observed Memorial Day on May 5, 1866, to honor soldiers killed in the American Civil War. Businesses closed, and people decorated soldiers' graves and flew flags at half-mast.

Major General John A. Logan in 1868 named May 30 as a special day for honoring the graves of Union soldiers. Logan served as commander in chief of the Grand Army of the Republic, an organization of Union veterans of the Civil War. They had charge of Memorial Day celebrations in the Northern States for many years. The American Legion took over this duty after World War I.

Sharron G. Uhler

Memory. See Computer (Parts of computers).

Memory is the ability to remember something that has been learned or experienced. Memory also refers to the brain's ability to store information. Memory is a vital part of the learning process. Without it, learning would be impossible. If your brain recorded nothing from the past, you would be unable to learn anything new. All your experiences would be lost as soon as they ended, and each new situation would be totally unfamiliar. Without memory, you would repeatedly have the same experiences for the "first time." Memory gives a richness to life—the pleasure of happy remembrances as well as the sorrow of unhappy ones.

Scientists learn more every day about what happens in the brain when it stores memories. Almost certainly, storing new memories involves chemical changes in the nerve cells of the brain or in the substances that carry messages across the tiny gaps between the nerve cells. These gaps are called *synapses.* Storing new memories also involves structural changes, such as changes in the physical structure of the brain's nerve cells.

Scientists also continue to learn more about which areas of the brain are involved in remembering. One important area is the *hippocampus,* part of a larger structure called the *cerebral cortex.* The cerebral cortex controls higher brain functions such as thinking, problem solving, decision making, and the use of language. Many people who suffer damage to the hippocampus have trouble remembering anything new.

The memory system

Psychologists divide a person's memory system into three types, each of which has a different time span. These types are called *sensory memory, short-term memory,* and *long-term memory.*

Sensory memory holds information for only a second or two. Suppose you look at a picture of a mountain. A nearly exact image of the mountain is stored briefly in your *visual sensory memory,* which involves your eyes and parts of your brain. However, the image quickly fades and disappears unless you make an active effort to think about it.

Short-term memory contains what you actively think about at any particular time. It can hold a fact for as long as you think about it. You use short-term memory when you look up a telephone number and repeat it to yourself until you dial it. Unless you continually repeat this information to yourself, it will fade after about 20 to 30 seconds.

Long-term memory can store facts, ideas, and experiences after you stop thinking about them. All conscious processing of information—such as when you think or when you solve problems—involves short-term memory working together with long-term memory. Psychologists refer to this combination as *working memory.* Long-term memory includes a huge amount of information, some of which lasts a lifetime. Experts believe that by the time a person dies, the long-term memory has stored hundreds of times the amount of information in a comprehensive encyclopedia, such as *World Book.*

Measuring memory

There are many methods to measure how much a person remembers. Three common methods are (1) recall, (2) recognition, and (3) relearning. Suppose you give a party and someone asks you a few weeks later who was there. The simplest way to find out how much you remember is to list as many names as you can. This is the method of *recall.*

In *recognition,* the person asking about your guests would give you a list of names. The list would include names of people who were at the party and of others who were not. You could then indicate which people were there. Most people can recognize more facts than they can recall. As a result, most students perform better on multiple-choice tests than on essay tests.

In *relearning,* you would memorize the party guest list after apparently forgetting it. Most people relearn information faster than they learned the information the first time. Scientists regard the difference in the time required for the original learning and for the relearning as

evidence of how much was remembered.

Why people forget

In general, people forget more and more as time passes. An hour after a party ends, you probably could remember most of the people who were there. Two days later, you might recall only a few of the guests. A month later, you probably would remember even fewer. Scientists have devoted much study to why the passage of time makes people unable to remember things they once knew. The chief explanations for forgetting include *interference, retrieval failure, motivated forgetting,* and *constructive processes.*

Interference occurs when the remembering of certain learned material blocks the memory of other learned material. If a friend moves, you may have difficulty recalling his or her new telephone number. The person's old number may keep coming to mind and interfering with your remembering the new one. But after you have thoroughly learned the new number, you may not even be able to recall the old one.

The above example illustrates two types of interference. Previously learned information may hamper a person's ability to remember new material. This hampering process is called *proactive interference.* Likewise, the learning of new facts may interfere with the memory of something previously learned. Such interference is known as *retroactive interference.*

Retrieval failure is the inability to recall information that has been stored in the memory. You probably have had the experience of being unable to think of a name or some other piece of information that was on the tip of your tongue. Later, the information came to you naturally and effortlessly. Such temporary loss of memory, which occurs frequently, is called *retrieval failure.* Scientists compare it to trying to find a misplaced object in a cluttered room. The information is not gone, but neither can it be recalled immediately.

Motivated forgetting occurs when people want to forget something. Some psychologists distinguish between two kinds of motivated forgetting, *suppression* and *repression.* In suppression, a person consciously tries to forget a memory. For example, singers might deliberately put out of their minds the memory of the last time they sang off key. In repression, a person unconsciously tries to forget a memory. Sigmund Freud, the Austrian physician who developed psychoanalysis as a method of treating mental illness, believed that people often get rid of memories of traumatic events through the process of repression. But scientists have not proved this theory.

Constructive processes can involve the creation of false memories. When you try to remember an event that happened years ago, you may recall only a few facts. Using those facts, you fill in the gaps with details that seem to make sense but may be untrue. The process of constructing probable happenings to tell a complete story is called *confabulation.* Confabulated memories seem real and are almost impossible to distinguish from memories of events that actually occurred.

Improving memory

Memory experts believe that people can, with practice, increase their ability to remember. One of the most important means of improving memory is the use of mental aids called *mnemonic devices* (pronounced *nih MAHN ihk*). Other techniques can also be used to help people improve their memory.

Mnemonic devices include rhymes, clues, mental pictures, and other methods. One of the simplest ways is to put the information into a rhyme. Many people remember the number of days in each month by using a verse that begins, "Thirty days hath September. . . ."

Another method provides clues by means of an *acronym,* a word formed from the first letters or syllables of other words. For example, the acronym *homes* could help a person remember the names of the Great Lakes—*Huron, Ontario, Michigan, Erie, Superior.*

A mental picture can be provided by the key-word method, which is particularly useful in learning foreign words. Suppose you want to remember that the German word *Gabel* (pronounced *GAH behl*) means *fork.* First, you think of a key word in English that sounds like the foreign word—for example, *gobble.* Next, you connect the two words through a mental image, such as that of a person gobbling food with a fork. From then on, to recall the meaning of *Gabel,* you would remember *gobble* and the stored image linking it to *fork.*

Mental pictures can also be used to remember names. When you meet a person for the first time, pick out a physical feature of the individual and relate it to his or her name. For example, if you meet a very tall man named Mr. Shackley, imagine his bumping his head on the roof of a shack. In the future, this image will help you remember his name when you see or think of him.

Mnemonic techniques work best for remembering lists of specific items, such as words or objects. They do not work well for learning complex materials, such as stories and poems. For this reason, many psychologists favor more general strategies for improving memory.

Other ways to improve memory. A good way to help remember a piece of information is to *rehearse* (repeat) it a number of times. You can rehearse aloud or quietly to yourself. The more you rehearse, the more lasting the memory will be. In addition to repeating the information over and over, rehearsal also can involve elaborating upon the information. For example, suppose you want to remember the year that the telephone was invented—1876. You might elaborate upon this information by reminding yourself that the Declaration of Independence was signed 100 years earlier.

Another memory aid involves making the surroundings in which you remember material similar to those in which you learned the material. For this reason, football coaches often require players to practice under conditions similar to those of an actual game.

Uncommon memory conditions

Exceptionally good memory. You sometimes hear of someone who has a "photographic memory," which supposedly works like a camera taking a picture. A person with such a memory would be able to take a quick mental picture of a textbook page or a scene. Later, the person could describe the page or scene perfectly by causing the image to reappear in his or her mind.

No one actually has a photographic memory. However, some people have a similar ability called *eidetic imagery.* An eidetic image is a picture that remains in a

person's mind for a few seconds after a scene has disappeared. People who have eidetic imagery can look at a scene briefly and then give a thorough description of the scene based on a mental image. But the image fades quickly and may be inaccurate. Eidetic imagery is rare. Only 5 to 10 percent of all children have this ability, and most of them lose it as they grow up.

Certain people possess an exceptionally good memory. They may be able to memorize the names of all the state capitals of the United States or hundreds of names and numbers from a telephone book. When such exceptional memory occurs in people with mental handicaps, psychologists refer to this condition as *savant* (pronounced *suh VAHNT) syndrome.*

Déjà vu (pronounced *DAY zhah VOO)* is the feeling of having already experienced a situation that is actually happening for the first time. For example, a person who goes to a restaurant in a foreign city for the first time may have the overwhelming sensation of having been there before. Episodes of déjà vu occur most often in people who have epilepsy. *Déjà vu* is a French term meaning *already seen.*

Memory disorders. Some memory disorders result from physical damage to the brain. Such physical damage may occur due to head injuries, drug abuse, infection, and other causes. For example, a blow to the head can cause a person to forget events that occurred before the injury. A person's inability to remember these events is called *retrograde amnesia.* How much memory loss occurs depends on the severity of the injury. Football players who receive a blow to the head might forget the few seconds just before the injury. Someone who suffers major brain damage in a car accident might lose months or even years of memories. Brain-injured people also can experience *anterograde amnesia.* This condition involves difficulty remembering events that occur after the injury.

Memory difficulties also may result from emotional shock. For example, a person who witnessed a horrible accident may forget details of the accident. Memory loss in the absence of physical injury is known as *psychogenic amnesia.* Elizabeth F. Loftus

Memphis was the first capital of ancient Egypt. According to tradition, Menes, who was the first king of Egypt, founded the city and made it his capital around 3100 B.C. Memphis stood near the site of present-day Cairo. During the Old Kingdom (2686-2181 B.C.), kings built pyramids at Giza and Saqqarah near Memphis. The city was Egypt's capital until the end of the Old Kingdom, and was an important religious and political center until about 330 B.C. Nothing remains of the ancient city itself. However, cemeteries and the pyramids at Giza and Saqqarah stand as reminders of the city's past glory.
Barbara Mertz

Memphis is the largest city in Tennessee. It lies on a bluff on the east bank of the Mississippi River in the southwest corner of the state. Memphis serves as the commercial and industrial center of west Tennessee and parts of neighboring Arkansas and Mississippi.

Cotton and river trade accounted for much of the city's early growth. By 1900, Memphis was the world's largest market for cotton and hardwood lumber. The city is still a leader in these activities. But industrial expansion after World War II ended in 1945 made Memphis one of the South's largest urban centers. The city also became a hub of higher education, medical care, and motel development, and a center for the recording and distribution of music.

Memphis was named for the ancient Egyptian capital of Memphis, which lay on the Nile River. Settlers chose the site because the nearby Wolf River flowed into the Mississippi and provided an excellent harbor. The bluff site also furnished protection from floods.

The city covers 288 square miles (746 square kilometers) and is the seat of Shelby County. The Memphis metropolitan area consists of Fayette, Shelby, and Tipton counties in Tennessee; Crittenden County, Arkansas; and De Soto County, Mississippi. The metropolitan area totals 3,092 square miles (8,008 square kilometers).

The Mississippi River flows to the west of Memphis, and the Tennessee-Mississippi state line forms the southern boundary of the city. Suburbs include Arlington, Bartlett, Collierville, Germantown, Lakeland, and Millington, Tennessee; Olive Branch and Southaven, Mississippi; and West Memphis, Arkansas, which lies west of the river. Millington is the home of Naval Support Activity Memphis.

Downtown Memphis extends $1 \frac{1}{2}$ miles (2.4 kilometers) along the Mississippi River. The Memphis Civic Center stands on the north edge of the downtown area. The Civic Center consists of local, state, and federal government buildings. In the southern end of downtown Memphis is Beale Street, where composer W. C. Handy worked as a musician. Handy made the street famous in his song "Beale Street Blues."

During the late 1900's, Memphis business and political leaders directed an extensive downtown redevelopment program. Completed projects included a convention center; Mud Island Park, a river park connected to the downtown area by a monorail; office and residential buildings; museums; a baseball stadium; and the Pyramid, a sports and entertainment arena. The program also included renovation of the Orpheum Theater, the Peabody Hotel, and Central Station and the renewal of Beale Street as an entertainment center.

Graceland, the estate of the famous rock singer Elvis Presley, lies in southern Memphis. Presley died in 1977 and was buried on the estate. Each year, hundreds of thousands of people visit the estate.

The people. Most of the people of Memphis were born in the United States. African Americans make up more than 60 percent of the city's population. Other ethnic groups include those of German, Irish, and English descent. The city also has rapidly growing communities of Hispanic Americans and Asian Americans.

© Mark E. Gibson, The Stock Market

Memphis is Tennessee's largest city and chief center of commerce, industry, and transportation. Downtown Memphis, *shown here,* stretches along the east bank of the Mississippi River.

Poverty is a major problem in Memphis. Many people live in crowded, run-down dwellings in areas north and south of the downtown district. Many have little education and few work skills.

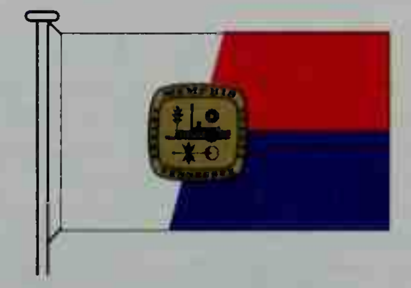
Like many other cities, Memphis has had racial problems. In 1968, the civil rights leader Martin Luther King, Jr., was assassinated in Memphis. James Earl Ray, a native of Illinois and an escaped convict, pleaded guilty to the murder in 1969. King had gone to Memphis to support a strike by city sanitation workers, most of whom were African American.

After King's death, the city worked to improve living conditions in the African American community. The city has sponsored major reforms in housing, education, and health care that have focused on the black community. A large number of blacks now take part in commerce and in city and state politics.

The economy. Memphis's economy once centered on cotton. The city is still one of the world's largest cotton markets, but a variety of other economic activities have been developed.

Memphis is the trade center of a region consisting of western Tennessee, eastern Arkansas, northern Mississippi, and southeastern Missouri. The city is also a major national distribution center. The Port of Memphis is one of the busiest inland ports on the Mississippi River. The port ships goods to all parts of the world. Major airlines use Memphis International Airport. Memphis is a busy air cargo center. It is the headquarters of FedEx Corporation, the nation's largest overnight air express delivery company. Truck lines and railroads carry cargo to and from the city. Memphis's location allows overnight truck delivery to almost 40 percent of the nation.

Service industries employ about 83 percent of the workers in Memphis and Shelby County. Health care is the most important service industry. The Memphis Medical Center includes the world-famous St. Jude Children's Research Hospital; the colleges of dentistry, medicine, nursing, and pharmacy of the University of Tennessee, Memphis; and a dozen full-service hospitals. Memphis is also the leading center for the wholesale trade of hardwood lumber.



Manufacturing and processing employ about 13 percent of the workers of Memphis and Shelby County. The chief manufacturing companies in Memphis produce chemicals, electrical equipment, electronic products, food and food products, nonelectrical machinery, and paper and related products. Several major food and food-processing companies have plants in Memphis.

Tourism has become a major industry in Memphis, contributing more than $1 billion a year to the local economy. Graceland, the estate of Elvis Presley, draws the most tourists. The National Civil Rights Museum, at the site of the assassination of Martin Luther King, Jr., receives visitors from around the world. It features exhibits on the history of the civil rights movement. Memphis has one daily newspaper, *The Commercial Appeal.*

Education. The Memphis public school system enrolls more than 118,000 students, about 86 percent of whom are African Americans. About 14,000 students in Memphis attend private schools. The city started to desegregate its public schools in 1961. But 10 years later, most black students still attended all-black or mostly black schools. In 1973, under a federal court order, the public school system began busing some black students to mostly white schools, and some white students to all-

Facts in brief

Population: *City*—650,100. *Metropolitan area*—1,135,614.
Area: *City*—288 mi² (746 km²). *Metropolitan area*—3,092 mi² (8,008 km²).
Climate: *Average temperature*—January, 40 °F (4 °C); July, 82 °F (28 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—52 in (132 cm).
Government: Mayor-council. *Terms*—4 years for the mayor and for the 13 council members.
Founded: 1819. Incorporated as a city in 1849.

Symbols of Memphis. The red, white, and blue in the flag of Memphis represent the United States and Tennessee, both of which use those colors in their flags. The flag includes the city seal. The steamboat on the seal symbolizes commerce.

black or mostly black schools. As a result of the court order, about 30,000 white public school students began attending private schools. Since then, a growing black population in Memphis has created a large African American majority in the public schools, and desegregation is no longer a major issue.

The University of Memphis, the city's largest institution of higher learning, has an enrollment of about 18,000. Other colleges and universities in Memphis include Christian Brothers University, Crichton College, LeMoyne-Owen College, Memphis College of Art, Rhodes College, Southern College of Optometry, Southwest Tennessee Community College, Tennessee Technology Center at Memphis, and the University of Tennessee, Memphis.

Cultural life. The Memphis Symphony Orchestra performs at the Eudora Auditorium. Local ballet and opera companies are also active in Memphis.

The Memphis Brooks Museum of Art has a collection of Italian Renaissance paintings and sculpture, plus numerous other exhibits. The Dixon Gallery has a noted collection of French impressionism. The Memphis College of Art, the University of Memphis, and several smaller galleries also feature various artwork. The Memphis Pink Palace Museum has exhibits on the natural history of the Memphis region. The National Ornamental Metal Museum exhibits metalwork. Theatre Memphis offers a regular season of plays. The Orpheum Theater presents touring Broadway plays and musicals.

The Memphis Public Library serves the city. It consists of a main library and 22 branches.

Recreation. Memphis has more than 70 parks. Overton Park, east of downtown, has one of the South's largest zoos. Mud Island Park, between the Wolf and Mississippi rivers, features a replica that is half a mile (800 meters) long of the lower Mississippi Valley . Shelby Farms covers 5,000 acres (2,000 hectares) at the city's eastern limits. The park includes Agricenter International, a center for agricultural research and exhibits.

The Memphis in May International Festival is one of the largest annual events held in the United States. It honors a different nation each year. Popular features of the event are the Beale Street Music Festival and the International Barbecue Contest. The Mid-South Fairgrounds includes the Coliseum, Liberty Bowl Memorial Stadium, and Tim McCarver Stadium. The Mid-South Fair, held in September, presents agricultural and commercial exhibits. The city is the home of the Memphis Grizzlies of the National Basketball Association.

Government. Memphis has a mayor-council form of government. The voters elect a mayor and 13 council members to four-year terms. Property and sales taxes provide most of the city's funds.

History. Chickasaw Indians lived in what is now the Memphis area long before Europeans first came there. Hernando de Soto, a Spanish explorer, arrived in the area in 1541 and became the first European to see the Mississippi River. In 1682, the French explorer René-Robert Cavelier, Sieur de La Salle, built Fort Prud'homme near what is now Memphis and claimed the area for France. By the 1700's, France, Britain, and Spain had claimed the Tennessee region. The United States gained control of the area in the late 1700's.

In 1818, the U.S. government bought much of western Tennessee from the Chickasaw. General Andrew Jackson, Judge John Overton, and General James Winchester became owners of 5,000 acres (2,000 hectares) of the land. In 1819, the three men organized a settlement there and named it Memphis.

Memphis was incorporated as a city in 1849. In 1860,

City of Memphis

Memphis lies on the Mississippi River in southwestern Tennessee. It is the largest city in the state and an important shipping center. The map shows points of interest in the Memphis area.

WORLD BOOK maps

it had a population of 23,000 and ranked as the South's sixth largest city. After the American Civil War began in 1861, Memphis became a military center for the Confederacy. The city fell to Union forces in 1862. In the 1870's, a series of yellow fever epidemics struck the city. About half the population fled. In 1878, the epidemics killed about 5,200 of the 19,600 people who lived in Memphis. The state legislature took away the city's charter in 1879.

By 1890, river trade had increased, and the population had climbed to 64,500. In 1892, a railroad bridge was completed across the Mississippi at Memphis. The bridge increased trade with the Southwest, and Memphis soon became the world's largest inland center for cotton and hardwood lumber. Memphis regained its charter in 1893. During the late 1800's, many freed slaves moved to Memphis from plantations and small towns. Many worked in the cotton and lumber mills.

In 1909, E. H. Crump was elected mayor of Memphis. Crump became one of the most powerful political bosses in the nation's history. Until his death in 1954, Crump controlled almost all politics in Memphis and some state politics as well.

By 1960, the city's population had grown to 498,000. During the 1960's, a building boom brought many new factories and skyscrapers to Memphis. Memphis International Airport opened in 1963. The area of Memphis increased by about 70 percent through annexation of suburbs. The city's population grew by about 25 percent, largely as a result of this annexation.

In the late 1960's and early 1970's, Memphis suffered from racial conflict and weak political leadership. Recognition of common interests, however, has helped blacks and whites work together to resolve racial conflicts in the city. Memphis shifted from a mayor-commission to a mayor-council government in 1968.

In 1979, Memphis began a two-year program called the Governor's Job Conference. The conference brought together business and government leaders and citizens from throughout the community to plan economic and social growth. One of the conference's most successful projects was the promotion of Memphis as "America's Distribution Center." By the mid-1980's, the city had become one of the nation's largest distribution centers.

Since the 1980's, the growing African American majority in Memphis has put increased emphasis on the educational and economic needs of the black community. In 1991, the voters of Memphis elected Willie Herenton mayor. Herenton became the first African American to be elected mayor of the city. He was reelected in 1995 and 1999. David Kushma

Menander, *muh NAN duhr* (342?-291? B.C.), was a Greek playwright who wrote more than 100 comedies. We know his work only through fragments of his plays, adaptations of his plots by Roman dramatists Plautus and Terence, and one whole play, *Dyscolos (The Grouch).*

Menander was born and lived in Athens. His comedies dramatize humorous situations, especially in love affairs, in middle-class society. The plays resemble many modern comedies that deal with problems of home life. Menander is noted for his plot construction, characterization, clear style, and sympathetic view of humanity. His plays offer gentle lessons about human relationships, but he intended them primarily to entertain audiences.

Menchú, *mayn CHOO,* **Rigoberta,** *ree goh BAIR tah* (1959-), a Guatemalan Quiché Indian, won the 1992 Nobel Peace Prize for her work to gain respect for the rights of Guatemala's American Indian peoples. Menchú was born into a poor family in Chimel, near Santa Cruz del Quiché. She became an agricultural laborer as a small child. In 1977, her father, Vicente Menchú, helped organize the Peasant Unity Committee, a group seeking rights for agricultural workers and land for peasants.

The Guatemalan government objected to the Menchú family's political activities. By 1981, Menchú's father, mother, and one of her brothers had been killed by the Guatemalan army. That year, Menchú fled Guatemala. She completed her autobiography, *I, Rigoberta Menchú: An Indian Woman in Guatemala,* in 1983. The book called attention to injustices suffered by Indians in Guatemala and to the human rights abuses of the Guatemalan military. A study published in 1998 charged that certain parts of Menchú's autobiography were inaccurate. Menchú denied the charges. John A. Booth

Mencius, *MEHN shee uhs* (390?-305? B.C.), was one of the most influential figures in the development of the Chinese philosophy called Confucianism. Mencius is best known for his belief that human nature is good. He also believed that the people of a nation were justified in deposing or even killing a bad ruler. Mencius defined a bad ruler as one who ignored the people's welfare and governed them unkindly. Many of Mencius's ideas appear in the *Mengzi* (also spelled *Meng-tzu),* a book that is probably a collection of his teachings.

Mencius was born in the state of Zou, in what is now Shantung Province. His real name was Meng Ke. The name *Mencius* is the Latin form of *Mengzi,* a title that means *Master Meng.* Scholars know nothing about Mencius's early life except for information in some unreliable legends. David R. Knechtges

See also **Confucianism** (Early Confucianism).

Mencken, H. L. (1880-1956), was an American journalist, critic, and editor. His robust, often savagely witty style and his tremendous productivity as a writer brought him distinction in almost every literary form he attempted. From about 1910 to 1940, he was the most important literary figure in the United States.

Henry Louis Mencken was born in Baltimore. He began his journalism career at the age of 18 as a reporter with the *Baltimore Morning Herald.* By the age of 25, he had risen to editor in chief. After the paper closed in 1906, Mencken joined the *Baltimore Sun* as Sunday editor. He worked for the *Sun* for the rest of his career, except for leaves of absence during the two world wars. Mencken became famous for his newspaper columns, in which he enjoyed attacking American taste and culture, ridiculing a wide range of popular beliefs.

In 1905, Mencken wrote the first book-length study of the British playwright George Bernard Shaw. Three years later, he completed *The Philosophy of Friedrich Nietzsche,* a study of the German philosopher.

From 1908 to 1923, Mencken wrote about 2,000 book reviews for the magazine *Smart Set,* which he edited with George Jean Nathan from 1914 to 1923. Under Mencken and Nathan, the magazine became a central

shaper of literary taste in America. In 1923, Mencken began a 10-year position as founding editor of the *American Mercury.* This magazine of humor and comments about American customs and politics appealed to sophisticated, intellectual readers. During this period, Mencken reached the height of his influence.

Mencken is best known for his monumental study *The American Language* (1919). In it, he examined the development of the English language in America, praising the acceptance of new words and forms of expression as a reflection of the American lifestyle.

Mencken's criticism and essays were collected in the six-volume *Prejudices* (1919-1927). His other works include three autobiographical volumes, *Happy Days, 1880-1892* (1940); *Newspaper Days, 1899-1906* (1941); and *Heathen Days, 1890-1936* (1943). Parts of his diary were published in 1990. Daniel Mark Fogel

Mendel, *MEHN duhl,* **Gregor Johann,** *GREHG uhr YOH hahn* (1822-1884), an Austrian botanist and monk, formulated the basic laws of heredity. His experiments with the breeding of garden peas led to the development of the science of genetics.

His life. Mendel was born in Heinzendorf, Austria (now Hynciče, near Krnov, in what is now the Czech Republic). His parents were peasants. In 1843, Mendel entered the monastery of St. Thomas in Brünn, Austria (now Brno, the Czech Republic). He became a priest in 1847. In 1851, the monastery sent Mendel to study science and mathematics at the University of Vienna. He returned to the monastery in 1853 and taught biology and physics at a local high school for the next 14 years. Mendel's fame came from his research in the monastery garden. In 1868, Mendel was elected abbot of the monastery. From then on, his administrative responsibilities limited his opportunities for research.

His work. In his experiments, Mendel studied the inheritance of seven pairs of traits in garden pea plants and in their seeds. These pairs included (1) rounded or wrinkled seeds and (2) tall or short plants.

Mendel bred and crossbred thousands of plants and observed the characteristics of each successive generation. Like all organisms that reproduce sexually, pea plants produce their offspring through the union of special sex cells called *gametes.* In pea plants, a male gamete, or sperm cell, combines with a female gamete, or egg cell, to form a seed.

Mendel concluded that plant traits are handed down through hereditary elements in the gametes. These elements are now called *genes.* He reasoned that each plant receives a pair of genes for each trait, one gene from each of its parents. Based on his experiments, he concluded that if a plant inherits two different genes for a trait, one gene will be *dominant* and the other will be *recessive.* The trait of the dominant gene will appear in the plant. For example, the gene for round seeds is dominant, and the gene for wrinkled seeds is recessive. A plant that inherits both genes will have round seeds.

Mendel also concluded that the pairs of genes *segregate* (separate) in a random fashion when a plant's gametes are formed. Thus, a parent plant hands down only one gene of each pair to its offspring. In addition, Mendel believed that a plant inherits each of its traits independently of other traits. These two conclusions are known as Mendel's *Law of Segregation* and his *Law of Independent Assortment.* Since Mendel's time, scientists have discovered some exceptions to his conclusions, but his theories in general have been proved. Mendel's results were published in 1866 but went unnoticed until 1900. Daniel L. Hartl

Mendeleev, *MEHN duh LAY uhf,* **Dmitri Ivanovich,** *DMEE trih ih VAH nuh vihch* (1834-1907), was a Russian chemist who developed a form of the *periodic law,* a basic principle in chemistry. His law states the properties of chemical elements recur in regular patterns when the elements are arranged according to their atomic weight. Mendeleev's work, together with that of the German chemist Julius Lothar Meyer, led to the *periodic table,* a systematic arrangement of the elements (see **Element, Chemical** [Periodic table of the elements]).

In 1869, Mendeleev proposed his arrangement of the elements in order of increasing atomic weight and according to similarity in properties. Mendeleev's table had blank spaces for unknown elements. Later, using the periodic law, he predicted the properties of three unknown elements. His predictions were confirmed by the discovery between 1875 and 1886 of three elements with these properties. Mendeleev also discovered the phenomenon of *critical temperature,* the temperature at which a gas or vapor may be liquefied by pressure. He was born in Tobolsk, Russia. O. Bertrand Ramsay

Mendelevium, *mehn duh LEE vee uhm* or *mehn duh LAY vee uhm,* is an artificially produced radioactive element. It has an *atomic number* (number of protons) of 101. Its chemical symbol is Md. Scientists have discovered 13 *isotopes* of mendelevium. Each isotope is a form of the element with 101 protons but a different number of neutrons. The *atomic mass numbers* (total numbers of protons and neutrons) of these isotopes range from 247 to 260. The most stable isotope has a mass number of 258 and a *half-life* of 55 days—that is, due to radioactive decay, only half the atoms in a sample of isotope 258 would be atoms of that isotope after 55 days.

In 1955, scientists at the Lawrence Radiation Laboratory (now Lawrence Berkeley National Laboratory) in Berkeley, California, claimed that they had produced element 101. They had bombarded einsteinium, whose atomic number is 99, with helium, whose atomic number is 2. The Berkeley scientists suggested the name *mendelevium* in honor of Russian chemist Dmitri Mendeleev. This name was accepted by the International Union of Pure and Applied Chemistry (IUPAC). The IUPAC is the recognized authority in crediting the discovery of elements and assigning names to them.

In 1986, the IUPAC and the International Union of Pure and Applied Physics formed a working group to review the histories of elements with atomic numbers from 101 to 109. In 1993, the IUPAC accepted the working group's decision to credit the discovery of mendelevium to work done, not in 1955, but in 1958 by a different group at the Berkeley Laboratory. Richard L. Hahn

Mendelsohn, *MEHN duhl suhn,* **Eric** (1887-1953), was a German architect noted for his bold geometric style. Mendelsohn attempted to create a new and expressive industrial and commercial architecture. His best-known structure is the Einstein Tower (1924), a laboratory and observatory in Potsdam. The building features sweeping curves typical of Mendelsohn's work.

Eric (also spelled Erich) Mendelsohn was born in Allenstein, East Prussia (now Olsztyn, Poland). He studied architecture in Munich, Germany. His most important German works included the Steinberg, Hermann & Co. factory (1923) in Luckenwalde and the Schocken department stores in Stuttgart (1927) and Chemnitz (1928).

In 1933, Mendelsohn emigrated to England, where he worked with architect Serge Chermayeff. Their best-known collaboration was the De La Warr Pavilion (1935) in Bexhill. Mendelsohn also practiced in Palestine (now Israel) in the late 1930's, designing hospitals in Haifa and Jerusalem. Mendelsohn settled in the United States in 1941. His major U.S. projects included the Maimonides Health Center (1950) in San Francisco and synagogues for several Midwestern cities, including Cleveland and St. Louis. Leland M. Roth

AdW Frobus

Mendelsohn's Einstein Tower in Potsdam, Germany, is his first major work. He designed the laboratory and observatory to symbolize the scientific investigation of the universe.

Mendelssohn, *MEHN duhl suhn,* **Felix** (1809-1847), was a German composer who was widely known and respected in his time. Mendelssohn also gained fame as a conductor and pianist. He also played a significant role in reviving interest in the music of German composer Johann Sebastian Bach. Mendelssohn held high standards of excellence in composition, performance, and musical training that have had an enormous effect on musicians in the 1800's and 1900's.

His life. Mendelssohn was born in Hamburg, Germany. He was the son of a wealthy banker and grandson of the German-Jewish philosopher Moses Mendelssohn. Many of Mendelssohn's ancestors were Jewish, but his father became Protestant after the family moved to Berlin in 1811. At that time, they added Bartholdy to their last name as a sign of their Protestantism. Mendelssohn's full name was Jakob Ludwig Felix Mendelssohn-Bartholdy.

Mendelssohn studied the piano with many respected teachers. He made his first public performance as a pianist when he was 9. When he was 10, he joined a choral society in Berlin called the Singakademie. The group performed Mendelssohn's choral composition "Psalm 19" that same year. In following years, the group presented many of his works. A conductor at the Singakademie, Carl Friedrich Zelter, became Mendelssohn's music teacher. Zelter introduced Mendelssohn to many musicians and intellectuals, including the German poet Johann Wolfgang von Goethe.

Although Mendelssohn continued performing during his teen-age years, he became increasingly interested in composition. When he was 17, he wrote an overture for *A Midsummer Night's Dream,* a comedy by the English playwright William Shakespeare. Mendelssohn later composed additional music for the play, including the well-known "Wedding March."

Mendelssohn's fame as a conductor, composer, and pianist grew rapidly during the 1830's and 1840's. He performed throughout Europe, making 10 trips to Great Britain. Britain's Queen Victoria greatly admired Mendelssohn, and his music was popular with British audiences. Mendelssohn's travels in England and Scotland inspired several compositions, including his overture *The Hebrides* (1832), also called *Fingal's Cave.*

One of Mendelssohn's most significant achievements was his role in reviving the music of Johann Sebastian Bach. In 1829, he conducted a performance of Bach's "Passion According to St. Matthew" (1729) at the Singakademie. It was the first time since Bach's death that this work had been performed. This event and Mendelssohn's enthusiasm for Bach's music generated a great renewal of interest in the music of the composer.

In 1835, Mendelssohn became the conductor of the famous Gewandhaus (Cloth Hall) Orchestra in Leipzig, Germany, a great honor for such a young conductor. The orchestra thrived and became highly respected under his leadership. In 1843, Mendelssohn formed a music academy in Leipzig. He attracted many outstanding musicians to its faculty, including German composer Robert Schumann. In 1837, Mendelssohn married Cécile Jeanrenaud, with whom he had five children. He died from an undiagnosed illness when he was only 38.

His music. Although Mendelssohn composed during the romantic period, his style grew directly from the classical music of the early 1800's. Mendelssohn's music adheres to traditional forms, emphasizes structural clarity, and contains many classical elements, including smooth *progressions* (changes) in harmony and *counterpoint* (combining several melodies at once). But his work has the emotion and dramatic intensity of romantic music. Also, like other romantic composers, Mendelssohn often found inspiration for his music in literature.

Mendelssohn wrote 12 early string symphonies, 4 later symphonies for full orchestra, and a choral sym-

phony. The *Scottish Symphony* (1842), the 3rd, and the *Italian Symphony* (1833), the 4th, are the most frequently performed. Most notable among his other works for orchestra are two piano concertos (1831 and 1837) and an outstanding violin concerto (1845). Mendelssohn wrote numerous choral works with religious themes. The oratorios *St. Paul* (1836) and *Elijah* (1846) are the best known. Mendelssohn's other works include eight collections of short piano pieces called *Songs Without Words* (1832-1843), incidental music for the theater, chamber compositions, and several operas. Daniel T. Politoske

Todd, R. Larry, ed. *Mendelssohn and His World.* Princeton, 1991.

Mendelssohn, *MEHN duhl suhn,* **Moses** (1729-1786), was a Jewish philosopher and scholar, and one of the most learned men of his time. He explored a number of philosophical issues. Mendelssohn was a founder of the German *Haskalah,* a religious cultural movement (see **Haskalah**). In his philosophy of religion, he emphasized reason and believed that human beings have an inborn power to know what is good and true. Mendelssohn wrote several works in German and Hebrew. In *Phädon* (1767), he discussed his belief in the soul's immortality. In *Jerusalem* (1783), he gave his interpretation of Judaism.

Mendelssohn was born in Dessau, Germany. He moved to Berlin in 1743, where he acquired advanced knowledge of history, Judaism, philosophy, and languages. Mendelssohn took an active part in Jewish cultural life. He worked for civil rights for German Jews and tried to improve Jews' knowledge of German by translating parts of the Bible into that language. In spite of his own traditional observance, Mendelssohn's role in the Berlin Haskalah made him extremely unpopular among Orthodox Jews. His Bible translation was the subject of a major controversy. Lawrence H. Schiffman

Menelaus, *MEHN uh LAY uhs,* a king of Sparta, was the husband of Helen of Troy. Paris, a Trojan prince, persuaded Helen to elope with him to Troy. Menelaus and his brother, Agamemnon, gathered an army and attacked Troy. After 10 years they took the city, and Menelaus recovered Helen. They wandered for 8 years but finally reached Sparta. They lived there for many years. See also **Helen of Troy.** Cynthia W. Shelmerdine

Menelik II (1844-1913) was one of the greatest emperors of Ethiopia. Menelik, whose name is also spelled Menilek, ruled from 1889 until his death. He expanded and modernized Ethiopia and made it an independent country at a time when the European powers were establishing colonies in Africa.

Menelik was born near present-day Addis Ababa. In 1889, he succeeded Yohannis IV as emperor of Ethiopia. That same year, Menelik signed the Treaty of Wichale with Italy. The treaty established the boundary between Ethiopia and Italy's colonial possessions along the Red Sea. However, Italy soon began to move into Ethiopian territory, and in 1893, Menelik canceled the treaty. In 1896, he won a decisive victory against the Italians near the town of Adwa. This battle marked the first time that an African army had defeated a major modern European power. Soon the major colonial powers recognized Ethiopia's independence.

Menelik then concentrated on expanding Ethiopia's territory and modernizing the country. He took over much land to the south and founded a new capital, Addis Ababa. He began the construction of a railway that, when completed, linked Addis Ababa to Djibouti. He also expanded trade and established the first modern schools and hospitals in Ethiopia. Peter P. Garretson

Menéndez de Avilés, *meh NEHN dehth theh ah vee LEHS,* **Pedro,** *PAY throh* (1519-1574), a Spanish naval captain, founded St. Augustine, the first permanent European settlement in what would become the United States. He established the settlement in Florida. Menéndez also forced French colonists out of Florida and gained control of the territory for Spain.

King Philip II of Spain had selected Menéndez to lead an expedition to Florida in 1565. The main purpose of the mission was to drive out a group of French settlers who had begun colonizing Florida in 1564. The king also wanted Menéndez to colonize Florida for Spain.

In 1565, Menéndez landed in Florida and founded the fortified settlement of St. Augustine. He then led about 500 men in an attack on France's Fort Caroline, near present-day Jacksonville. The Spanish seized the fort, killing about 130 French troops. They also took as prisoners over 200 men, including the French commander, and executed them. Menéndez's victory ended French attempts to colonize eastern Florida. In the next few years, he established several more fortified settlements in what is now the southeastern United States. He was Spain's governor of Florida from 1568 until his death in 1574.

Menéndez was born in the Asturias region of northern Spain. He became a sailor at the age of 14. He was appointed captain general of Spain's fleet in the West Indies in 1554. Paul David Nelson

Mengele, *MEHNG geh luh,* **Josef** (1911-1979), a German doctor, personally selected over 400,000 prisoners to die in gas chambers at Auschwitz, a Nazi concentration camp during World War II (1939-1945). He also conducted horrible experiments on inmates, hoping to produce a race of people with blond hair and blue eyes. Camp inmates called him the "Angel of Death."

Mengele was born in Günzburg, Germany. He became a doctor and joined the Nazi Party in 1938. Mengele served at Auschwitz from 1943 until 1945. U.S. troops captured Mengele but freed him before learning of his role at Auschwitz. From 1949 to 1959, he lived in Argentina. In 1959, West Germany issued a warrant for his arrest for committing war crimes and mass murders. Mengele fled first to Paraguay and later to Brazil. He died in 1979. His death was not uncovered until 1985, when his remains were found buried at a cemetery in Embu, Brazil, under a false name. Scientific tests proved the remains to be Mengele's. Gerald L. Posner

Menhaden, *mehn HAY duhn,* is a fish that lives in the Atlantic Ocean off the Americas from Nova Scotia to Brazil. Its name comes from an Indian word meaning *that which enriches the earth.* Early Indians often used the menhaden for fertilizing crops. It is also called *pogy, mossbunker, bunker, fatback, shad,* and *bugmouth.* The fish grows from 12 to 18 inches (30 to 46 centimeters) long and weighs from $\frac{3}{4}$ to 1 pound (0.3 to 0.5 kilogram).

Large schools of young menhaden appear along the East Coast of the United States in the summer. They swim near the surface and make easy prey for fishing

fleets as well as for sharks, tuna, and other flesh-eating fishes. Menhaden feed chiefly on tiny aquatic organisms called *plankton* (see **Plankton**).

Menhaden can be eaten by people, but only small quantities of the fish are sold for food. The fish yield a valuable oil, used in the manufacture of soap, linoleum, oilskin garments, paint, and varnish, and in the tempering of steel. Ground menhaden meal serves as livestock feed, and menhaden scrap is used for fertilizer.

Robert R. Rofen

Scientific classification. Menhaden are in the herring family, Clupeidae. They are members of the genus *Brevoortia.*

Ménière's disease. See **Ear** (Diseases).

Meningitis, *MEHN ihn JY tihs,* is a disease that affects the membranes covering the brain and spinal cord. These membranes are called the *meninges.* The disease also affects the *cerebrospinal fluid,* which surrounds the brain and spinal cord. Meningitis results from infection by bacteria, viruses, fungi, or other microbes. This article discusses bacterial and viral meningitis, the two most common forms of the disease.

Meningitis can attack people of all ages, but it most frequently strikes infants and children. Most victims recover completely from it. But bacterial meningitis can cause severe brain damage and even death. This form also can result in deafness, paralysis, muscle weakness, mental retardation, blindness, and changes in behavior.

People with physical conditions that weaken the body's resistance to infection have the greatest risk of getting meningitis. Such conditions include sickle cell anemia, the lack of a spleen, or the lack of infection-fighting proteins called *immunoglobulins.*

How meningitis develops. In most cases, the bacteria or viruses that cause meningitis inhabit the respiratory organs. The microbes pass into the bloodstream and are carried to the brain, where they infect the meninges and the cerebrospinal fluid. A variety of chemical changes occur in the brain, and the brain may swell.

Many types of bacteria cause meningitis. But most cases of bacterial meningitis result from infection by one of three types of bacteria—*Neisseria meningitidis, Haemophilus influenzae* type b, and *Streptococcus pneumoniae.* Several viruses also cause meningitis.

Symptoms and diagnosis. In general, the symptoms of bacterial meningitis are more severe than those of viral meningitis. The symptoms also vary with the age of the patient. Among infants and young children, the symptoms include fever, nausea, vomiting, loss of appetite, and sleepiness. Some children experience convulsions or uncontrollable jerking of the limbs. Among older children and adults, symptoms often include headache, back pain, muscle aches, and sensitivity to light in the eyes. Many victims also have a stiff neck.

Doctors diagnose meningitis by examining a sample of the patient's cerebrospinal fluid. The sample is obtained by inserting a needle between the vertebrae in the lower part of the back. This procedure is known as a *lumbar puncture* or *spinal tap.* The cerebrospinal fluid of victims of bacterial meningitis contains a high level of protein and a low level of glucose. The fluid of most patients with viral meningitis has a normal or high level of protein and a normal level of glucose. To identify the type of bacterium or virus involved, the patient's cerebrospinal fluid is further tested in various ways.

Treatment and prevention. A patient with meningitis should be under a doctor's care. No specific treatment is effective against viral meningitis. Bacterial meningitis is treated with antibiotics, which greatly reduce the risk of dying from the disease. The antibiotic used depends on the bacteria involved. The most widely used antibiotics for bacterial meningitis are penicillin, ampicillin, chloramphenicol, and cephalosporins. Most patients recover from meningitis in several weeks.

Some forms of bacterial and viral meningitis are contagious. Rifampin, an antibiotic, helps protect against the spread of meningitis caused by *Neisseria meningitidis* and *Haemophilus influenzae* type b. Doctors usually administer rifampin to people who come into close contact with a meningitis patient. There are vaccines to protect against certain types of bacterial meningitis. Doctors recommend that all infants be vaccinated for *Haemophilus influenzae* type b meningitis. There are no effective ways to prevent viral meningitis. Sheldon L. Kaplan

Menninger, *MEHN ihng uhr,* **Karl Augustus** (1893-1990), was an American psychiatrist whose writings influenced public attitudes toward mental illness. He helped found the Menninger Clinic, a leading psychiatric center. His most influential book was *The Human Mind* (1930). His other works include *Man Against Himself* (1938), *Love Against Hate* (1942), *The Crime of Punishment* (1968), and *Whatever Became of Sin?* (1973).

Menninger was born in Topeka, Kansas. He received his M.D. degree from Harvard University.

Nancy C. Andreasen

Menninger, *MEHN ihng uhr,* **William Claire** (1899-1966), was a leading American psychiatrist. He and his brother Karl A. Menninger and their father, Charles F. Menninger, founded the Menninger Clinic, a psychiatric center that became internationally famous. During World War II (1939-1945), he served as chief consultant on psychiatry to the surgeon general of the United States Army and won the Distinguished Service Medal. He also became a leader in the Boy Scout movement.

Menninger was born in Topeka, Kansas. He received his M.D. degree from Cornell University. His writings include *Psychiatry in a Troubled World* (1948) and *Psychiatry: Its Evolution and Present Status* (1948).

Nancy C. Andreasen

Menninger Clinic, *MEHN ihng uhr,* a nonprofit organization in Topeka, Kansas, is one of the world's leading psychiatric centers. The clinic treats mentally ill patients, trains psychiatrists and other mental health professionals, conducts research, and develops programs in the social application of psychiatry.

The clinic includes two psychiatric hospitals—C. F. Menninger Memorial Hospital and Children's Hospital. It also offers a wide range of outpatient services.

The clinic's Karl Menninger School of Psychiatry and Mental Health Sciences is a major training center for mental health professionals. The Menninger Management Institute offers seminars and consultation for leaders in business, government, and medicine. The clinic also does wide research in human behavior. The Menninger Clinic was established in 1925 by three physicians—Charles F. Menninger and two of his sons, Karl and William. Critically reviewed by the Menninger Clinic

See also **Menninger, Karl A.; Menninger, William C.**

Mennonites, *MEHN uh nyts,* belong to a Protestant group that emphasizes a simple style of life and worship. They base their beliefs on the Bible, especially the New Testament. Mennonites try to live according to the Sermon on the Mount (Matthew 5-7). They believe the Bible forbids them from going to war, swearing oaths, or holding offices that require the use of force.

The first Mennonites belonged to a church organized in Zurich, Switzerland, in 1525. The members called themselves *Swiss Brethren.* They believed that church and state should be separate, and that Reformation leaders had not reformed the church enough (see **Reformation**). They also believed that baptism and church membership should be given only to people who are mature enough to make a thorough commitment to the church and demonstrate sincerity in their way of life. These early Mennonites were nicknamed *Anabaptists,* which means *rebaptizers* (see **Anabaptists**). The name *Mennonite* came from Menno Simons, a Roman Catholic priest who led the Anabaptists beginning in the mid-1530's. The Mennonites later split into groups, including the Amish, and became increasingly diverse.

Mennonites often migrated to escape persecution. Many moved to Pennsylvania in the early 1700's and became part of the group called Pennsylvania Dutch (see **Pennsylvania Dutch**). Dutch Mennonites began settling in Polish West Prussia in the 1500's. Some of them moved to Pennsylvania in 1683 after William Penn, the English Quaker who founded Pennsylvania, offered them religious freedom. Many West Prussian Mennonites of Dutch descent moved to Russia in the late 1700's. In the 1870's, many of them moved to Canada and to the Great Plains states. Leland Harder

See also **Amish; Kansas** (picture: Mennonite women).

Menominee Indians, *muh NAHM uh nee,* are a tribe that has lived in the Wisconsin and Upper Michigan region for over 5,000 years. The Menominee once occupied an area of about $9\frac{1}{2}$ million acres (3.8 million hectares). They lived by hunting and gathering food. The name *Menominee* means *wild rice people.* The Indians harvested wild rice from the water by canoe.

Treaties with the United States reduced Menominee lands to a reservation of 235,000 acres (95,000 hectares). Today, the reservation's economy depends on a lumber operation, including a sawmill. According to the 2000 U.S. census, there are about 7,900 Menominee Indians.

In 1953, the U.S. government adopted a policy of *termination* as part of a national program to make Indians independent. Termination called for ending federal support and protection of certain reservation Indians. With this policy, the government abolished the Menominee reservation in 1961. Congress no longer recognized the Menominee as an Indian tribe. It also withdrew the protection and benefits that treaties had guaranteed the Menominee. Termination brought economic hardship and threatened to destroy the tribe's culture.

The Menominee campaigned to have the Menominee termination reversed. In 1973, they regained their treaty rights and tribal status. The government reestablished the Menominee reservation in 1975. Ada E. Deer

Menopause, *MEHN uh pawz,* is the time in a woman's life when her menstrual periods stop. Most women have their last menstrual period between the ages of 45 and 55. The last menstrual period marks the end of a woman's natural childbearing years. Menopause is often called *the change of life.*

The term *menopause* technically refers to a woman's final menstrual period. However, the term is also commonly used to refer to the female *climacteric,* a period of 7 to 10 years of gradual changes in the body that lead to and follow the end of menstruation. The climacteric ends 1 year after a woman's last period. The end of menstruation before the age of 40 is premature and should be discussed with a physician.

Menopause results from a decline in the function of the *ovaries,* two organs that produce the egg cells and hormones needed for reproduction. As a woman grows older, her ovaries secrete increasingly smaller amounts of *estrogen* and *progesterone,* hormones that play a major role in the menstrual cycle. Eventually, levels of these hormones drop so low that menstruation ceases.

Symptoms of menopause vary greatly from woman to woman. In most women, menstruation becomes less and less regular for several months or years before ending. However, vaginal bleeding between periods may indicate a serious problem. Most menopausal women experience *hot flashes,* sudden feelings of heat, often followed by sweat and chills. Hot flashes that occur during sleep are called *night sweats.* As estrogen levels decrease, the lining of the vagina becomes thinner and drier. This condition can cause discomfort during sexual intercourse and can contribute to vaginal infections. Vaginal lubricants may relieve discomfort.

In addition to physical symptoms, many women have mood changes during menopause. However, the relationship between hormonal changes and emotions is unclear. Various other factors—such as the aging process and changes in lifestyle—may also affect emotions.

After menopause, a woman's risk of developing *osteoporosis* and heart disease increases greatly because of the decline of estrogens. Osteoporosis is the weakening of bones through the loss of bone tissue.

Physicians often prescribe hormone therapy to relieve or prevent many menopausal symptoms and to reduce the risk of osteoporosis and heart disease after menopause. Such therapy involves the use of drugs that contain forms of estrogen and progesterone. For the majority of women, hormone therapy involves few or no health risks. However, women with a history of certain problems, such as breast cancer or blood clots, may increase their chances of developing further problems by taking hormones. A woman should discuss any risks with her physician. Lynn J. Romrell

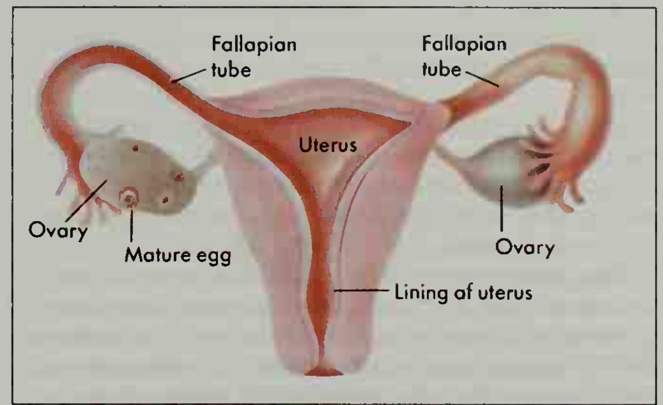
Menotti, *muh NAHT ee,* **Gian Carlo,** *jahn KAHR loh* (1911-), an American composer, wrote some of the most popular operas of the mid-1900's. Unlike most composers, he also writes the *librettos* (words) for his operas and stages most of their premieres. Menotti won the 1950 Pulitzer Prize for music for *The Consul* (1950) and the 1955 prize for *The Saint of Bleecker Street* (1954).

Menotti's first performed opera, *Amelia Goes to the Ball,* was staged in 1938 at the Metropolitan Opera. In 1947, his tragedy *The Medium* (1946) and comedy *The Telephone* (1947) had long runs on Broadway. Menotti's next stage successes were *The Consul,* about political refugees in Europe, and *The Saint of Bleecker Street,* about life in New York City's Italian section. He wrote

Amahl and the Night Visitors, perhaps his best-known opera, for TV in 1951. Based on the story of the Three Wise Men, it has been rerun often at Christmas.



Menotti was born in Cadegliano, near Milan, Italy, and moved to the United States in 1928. In 1958, he founded the Festival of Two Worlds, an international arts festival held each summer in Spoleto, Italy. In 1977, Menotti founded a similar annual festival, Spoleto Festival U.S.A., in Charleston, South Carolina. Richard Jackson

Mensheviks, *MEHN shuh vihks,* were members of a group in the Russian Social Democratic Labor Party. In 1903, this Marxist party split over a disagreement about membership. V. I. Lenin, a Russian revolutionary, became the leader of the *bolshinstvo* (majority), or Bolsheviks. His opponents became known as the *menshinstvo* (minority), or Mensheviks. The Bolsheviks favored party membership restricted to a small number of professional revolutionaries. The Mensheviks wanted fewer limitations on membership. See also **Bolsheviks; Lenin, V. I.**

Menstruation, *MEHN stru AY shuhn,* is the loss of blood and cells that occurs about once a month in most women of childbearing age. During each month, blood

Parts of the female reproductive system

WORLD BOOK illustrations by Charles Wellek

The four phases of the menstrual cycle

Menstrual phase begins about 14 days after an egg leaves the ovary. If the egg is not fertilized, it cannot attach to the uterine wall. It dies and passes out of the body. The ovaries stop supplying hormones to support the uterine lining, which begins to break down and shed. During this shedding, which is called the *menstrual period* or the *menses,* most of the lining and about $1\frac{1}{2}$ ounces (44 milliliters) of blood are discharged. The beginning of menses is Day 1 of the menstrual cycle.

Degenerating follicle

Degenerating lining

Follicular phase. The decrease of estrogen before menses helps the pituitary gland release *follicle-stimulating hormone* (FSH) into the bloodstream. The hormone causes an egg to ripen within a *follicle* (tiny sac) in an ovary. The cells around the growing egg secrete *estradiol,* a form of estrogen. As the estrogen levels rise, uterine bleeding stops and the lining of the uterus thickens to receive a fertilized egg.

Growing egg within follicle

Uterus lining

Ovulation. The largest egg follicle stimulates the pituitary gland to release a surge of *luteinizing hormone* (LH). This hormone causes *ovulation,* the release of the mature egg from its follicle. The egg travels to the uterus through the *fallopian tube,* where it may be fertilized by a male sex cell called a *sperm.* Ovulation takes place at about Day 14, or halfway through the menstrual cycle.

Ovulation

Growing lining

Luteal phase. The LH surge causes the empty follicle to form a body of cells called a *corpus luteum* (CL), which secretes estrogen and progesterone. Progesterone further prepares the uterus so a fertilized egg may attach to it. If fertilization occurs, the menstrual cycle stops until after the baby is born. If the egg is not fertilized, the CL decreases secretion of both estrogen and progesterone, and the uterine lining breaks down. As estrogen levels fall, the pituitary releases FSH and more follicles start to develop in the ovary.

Corpus luteum

Mature lining

and cells build up in the lining of a woman's *uterus* (womb), a hollow, pear-shaped organ that holds a baby during pregnancy. The thickening of the lining prepares the uterus for pregnancy. If pregnancy does not occur, the lining breaks down. The blood and cells are discharged through the *vagina,* which is a canal that leads from the uterus to the outside of the body. The process of menstruation lasts from three to seven days, and this period of time is called the *menstrual period,* or the *menses.*

Most girls experience their first menstrual period between the ages of 10 and 16. A woman stops having menstrual periods during a time of life called *menopause,* which occurs between the ages of 45 and 55 in most women.

The menstrual cycle. Menstruation is part of the *menstrual cycle,* the process that prepares a woman for pregnancy. This cycle repeats itself every 24 to 32 days during the reproductive years of most women. Several hormones regulate the phases of the menstrual cycle.

During menstruation, some *eggs* (female sex cells) begin to mature in the *ovaries,* two organs located near the uterus. As the eggs develop, the surrounding cells release *estradiol* (one of the estrogen hormones) into the bloodstream. As the estrogen level increases, menstrual bleeding stops and the lining of the uterus thickens in preparation for receiving a fertilized egg. The increase in estrogen also causes the pituitary gland to release a hormone that travels to the ovaries and causes the most mature egg to be released. The release of the egg, called *ovulation,* occurs about 14 days before the next menstrual period. The egg travels to the uterus through the *fallopian tube.* After ovulation, the ovary that has just released the egg produces another hormone, *progesterone,* which prepares the uterine wall so that *implantation* (attachment) of the fertilized egg may occur (see **Progesterone**).

Fertilization occurs if the egg unites with a male sex cell called a *sperm* in the fallopian tube. The fertilized egg attaches to the uterine wall and continues its nine-month development into a baby (see **Reproduction, Human**). The *placenta,* an organ that supplies food and oxygen to the baby, secretes hormones that prevent menstruation during pregnancy. If the egg is not fertilized, there is no placenta to secrete hormones. Thus, the uterine lining breaks down and is shed about 14 days after ovulation.

Effects of menstruation. Some women have mild to moderate abdominal cramps a few days before or during menstruation. This discomfort, called *dysmenorrhea,* results from contractions of the uterus and is usually normal. During the days before menstruation begins, some women experience emotional or physical symptoms that may include depression, anxiety, fatigue, headache, body swelling, or pain in the breasts. This condition is called *premenstrual syndrome* (PMS).

Menstruation signifies good health if it occurs regularly and without excessive pain, fatigue, or blood loss. Most women carry on their usual activities. Menstrual discharge can be absorbed either by a *sanitary napkin,* a disposable pad that covers the vaginal opening, or by a *tampon,* a roll of absorbent material worn inside the vagina.

The most common reason for a young woman to miss a menstrual period is pregnancy. Other reasons include emotional stress, weight loss, and abnormal hormonal balance. If a woman frequently misses her period or if it occurs less often than every 35 days, she should consult a doctor. Mona M. Shangold

Mental health. See **Health** (Elements of mental health).

Mental illness is any disease of the mind or brain that seriously affects a person's thoughts, emotions, personality, or behavior. Symptoms of mental illness may include extreme moods, such as excessive sadness or anxiety, or a decreased ability to think clearly or remember well. Almost everyone experiences mood swings or finds it difficult to think clearly from time to time. A mentally ill person, however, has severe symptoms that damage the person's ability to function effectively in everyday activities and situations.

Mental illness has many forms, and it affects people in all nations and at all economic levels. In the United States, approximately 3 percent of the population have a severe mental illness. But about 40 percent of Americans will experience a mental illness at some time in their lives. Although milder mental illnesses sometimes pass without treatment, severe cases of mental illness require professional treatment.

Mental health professionals have made important advances in the treatment of mental illness since 1950. Treatment methods used today usually help people recover from their symptoms more quickly than in the past. The availability of effective treatment has helped to reduce the fear, disgrace, and shame that has surrounded mental illness for centuries. Most people with mental illness can return to leading normal, productive lives after obtaining appropriate treatment.

Mental health professionals sometimes refer to mental illnesses as *mental disorders* or *psychiatric illnesses.* The terms *neurosis* and *psychosis* are sometimes used to describe the severity of various mental illnesses. A neurosis is a mild disorder that causes distress but does not interfere greatly with a person's everyday activities. A psychosis is a severe mental disorder that prevents an individual from functioning in a normal manner. *Insanity* is a legal rather than a medical term, which is used to describe a mental illness so severe that the person is considered not legally responsible for his or her acts. In everyday language, people may call a mental illness that occurs suddenly and requires rapid treatment a *nervous breakdown,* but mental health professionals do not use this term.

Kinds of mental illnesses

There are many different kinds of mental illnesses. The standard classification systems describe more than 100 types of mental disorders, which are divided into broad categories. These categories include delirium, dementia, schizophrenia, mood disorders, anxiety disorders, dissociative disorders, somatoform disorders, personality disorders, eating disorders, and substance use disorders.

Delirium is a disorder in which a person loses awareness of his or her surroundings. People with delirium are easily distracted and confused. At times they do not

know where they are or who they are, and they act and speak in a disorganized manner. People usually develop this disorder during a serious physical illness. Causes of delirium include infection, head injury, liver or kidney disease, and drug use or drug withdrawal. Most delirium cases begin suddenly and last no longer than a week.

Dementia is characterized by a decrease in mental ability, especially memory and judgment. People with dementia may forget names, conversations, or recent events. They often neglect personal hygiene and disregard social rules. Dementia occurs mainly in elderly people and results from illnesses that destroy brain tissue, such as Alzheimer's disease.

Schizophrenia is a severe mental disorder that affects many aspects of thinking, emotion, perception, and behavior. This mental illness is defined by the presence of one or more characteristic symptoms, such as hearing voices when no one is around or irrationally feeling persecuted. These symptoms are usually accompanied by a significant decline in the ability to function in many areas, including work, school, and relationships with other people.

The characteristic symptoms of schizophrenia can be divided into (1) positive symptoms and (2) negative symptoms. Positive symptoms represent distortions or exaggerations of normal emotions or mental abilities. They include hallucinations, delusions, disorganized speech, and disorganized or peculiar behavior. Negative symptoms represent a decrease in or loss of normal emotions or mental abilities. They include decreased speech, dulled emotions, and difficulty in beginning and completing goal-directed activities.

Schizophrenia usually strikes during the late teens or early 20's. The cause of schizophrenia remains unknown, but evidence suggests that the disease results from physical or chemical changes in the brain. These changes are difficult to reverse completely with the treatment methods currently available.

Mood disorders, also known as *affective disorders,* mainly involve disturbances in the person's mood. The two chief mood disorders are *major depression* (extreme sadness) and *mania* (extreme happiness and overactivity). People with *bipolar disorder,* also called *manic-depressive illness,* suffer from alternating periods of depression and mania. Mood disorders are usually *episodic*—that is, the person experiences mood disturbances at relatively brief, distinct periods during the course of the illness. People with mood disorders typically return to normal levels of functioning after treatment.

Most people with depression feel sad, hopeless, and worthless. Many also suffer from insomnia and loss of appetite and have trouble concentrating. Some people with depression move and think slowly, but others feel restless. Some feel so hopeless and discouraged that they consider or attempt suicide. About 15 percent of people who seek treatment for depression commit suicide.

A person with mania appears excessively and inappropriately happy and confident. The happy mood may shift suddenly to irritability, sometimes leading to angry outbursts. The person's thoughts may jump from one topic to another, producing rapid and rambling speech. People with mania move quickly, work energetically, and need little sleep. They shift restlessly from project to project but seldom complete any particular task. Most periods of mania begin suddenly, last for a few days or weeks, and then end abruptly.

Anxiety disorders are mental illnesses in which a person experiences excessive and unreasonable fear and anxiousness. They include (1) panic disorder, (2) obsessive-compulsive disorder, (3) generalized anxiety, and (4) phobias.

Panic disorder is characterized by *panic attacks* (sudden periods of intense fear). Symptoms of panic attacks include shortness of breath, rapid heartbeat, dizziness, numbness, sweating, and trembling. A fear of death often accompanies these physical disturbances. Most panic attacks last several minutes. Many people experience a panic attack at some time in their lives, but this does not mean that they have a disorder. Panic disorder results when the number of attacks or the persistent fear that another attack will occur makes it difficult for someone to carry out normal daily activities. For example, a man with panic disorder may refuse to go to work because he fears that he might have an attack while driving his car.

Obsessive-compulsive disorder is characterized by illogical and uncontrollable thoughts or impulses that result in *obsessions* or *compulsions.* Obsessions are persistent thoughts that the person considers senseless or terrible but cannot ignore. The most common obsessions include thoughts of committing violent acts or becoming infected by germs. Compulsions are actions

Mental illness terms

Anxiety is a condition of worry, tension, or uneasiness produced by the anticipation of some danger whose source may be largely unknown.
Compulsion is an irresistible impulse to perform a certain action again and again.
Delusion is a false belief that a person maintains in spite of evidence that proves it untrue.
Dementia is decreased mental ability, especially in memory and judgment, caused by conditions that destroy brain tissue.
Eating disorder is a condition characterized by severe disturbances in eating behavior and body image.
Hallucination is the perception of something that is not actually present.
Major depression is a mental disorder characterized by feelings of deep sadness, hopelessness, and worthlessness.
Mania means a mental disorder that involves extreme optimism and excessive energy, often accompanied by uncontrollable irritability and anger.
Mood disorder is a mental illness in which people experience severe disturbances in their feelings and general state of mind.
Obsession is a recurring thought that a person considers senseless or terrible but cannot ignore.
Personality disorder is a condition characterized by patterns of thinking and behavior that create significant difficulties in relationships with other people.
Phobia means a strong, unreasonable fear of a particular object or situation.
Schizophrenia is a severe mental disorder characterized by psychotic symptoms, such as delusions and hallucinations. These symptoms are accompanied by a significant decline in the ability to function in many areas, including work, school, and relationships with other people.
Unconscious refers to thoughts and feelings that a person is not directly or fully aware of.

performed again and again with little purpose, such as repeated handwashing or counting objects.

People with compulsions sometimes believe their actions will produce or prevent some future event. For example, a girl may believe her father will die if she does not perform a series of ritualistic actions each day. People with compulsions usually realize the senselessness of their behavior and do not enjoy performing the repetitive rituals. In severe cases, the compulsion becomes the person's major activity and thus prevents the individual from leading a normal life.

Generalized anxiety is a persistent fear without obvious cause that lasts 6 months or longer. Its symptoms include muscle tension, nausea, rapid heartbeat, and hot or cold spells. People with generalized anxiety constantly worry that something terrible will happen to them. This makes them impatient and irritable, and they may find it difficult to get along with other people.

Phobias are persistent, strong fears of certain objects or situations. Common phobias include *agoraphobia* (the fear of large open spaces) and *claustrophobia* (the fear of small enclosed spaces). A person suffering from a phobia has a strong desire to avoid the dreaded object or situation. If forced into contact with the cause of the phobia, the individual may panic. Most people have at least one phobia. Phobias become a disorder when they seriously interfere with a person's daily activities.

Dissociative disorders involve a loss or change of memory or identity. In a dissociative disorder called *psychogenic amnesia,* a person forgets his or her past. In a similar disorder, called *psychogenic fugue* (pronounced *fyoog*), the individual not only forgets the past but also travels away to live in a new location and assumes a new identity. People who suffer from *depersonalization disorder* feel as if they are watching themselves from a distance and have no control over their actions. In *multiple personality disorder,* the individual has two or more distinct personalities, each of which dominates at certain times.

Somatoform disorders are mental illnesses in which a person experiences physical symptoms with no explainable cause. Symptoms that commonly occur in somatoform disorders include chest pain, shortness of breath, sexual problems, and muscle weakness or paralysis. People who suffer from a somatoform disorder called *hypochondriasis* constantly fear disease. They interpret minor symptoms as indicators of serious illnesses. Patients with somatoform disorders may persistently seek unnecessary medical treatments, including medication and surgery.

Personality disorders are characterized by behavioral traits that create significant difficulties in personal relationships. For example, *antisocial personality disorder* is characterized by aggressive and harmful behavior that first occurs before the early teens. Such behavior includes lying, stealing, fighting, and resisting authority. During adulthood, people with this disorder often have difficulty keeping a job or accepting responsibility.

People with *borderline personality disorder* often have unstable personal relationships, problems with self-identity, and very noticeable mood changes. They may also act impulsively in potentially self-damaging ways, such as shoplifting, drug use, or reckless driving.

Individuals who suffer from *paranoid personality disorder* are overly suspicious, cautious, and secretive. They may believe that people are watching them or talking about them. They often criticize others but have difficulty accepting criticism.

People with *obsessive-compulsive personality disorder* attach great importance to being organized. They strive for efficiency and may spend a great deal of time making lists and schedules. But they are also indecisive and seldom accomplish anything. They often make unreasonable demands on others and have difficulty expressing emotions.

Eating disorders include *anorexia nervosa* and *bulimia.* Both of these disorders are characterized by an extreme fear of gaining weight or becoming fat. Both are much more common in women than men and are especially common in the teen years. A girl with anorexia nervosa has a distorted image of her body, believing that she is fat even though her weight is below normal. She will do whatever she can to lose more weight, including dieting, fasting, or exercising. In severe cases, this condition is life-threatening. People with bulimia have frequent and uncontrollable periods of overeating called *binges.* After binging, most people with bulimia make themselves vomit or use laxatives to prevent weight gain.

Substance use disorders involve the abuse of alcohol and certain other drugs, including amphetamines, barbiturates, cocaine, and heroin. Because drug abuse physically affects the brain, it can cause extreme changes in a person's behavior, mood, and personality. Mental illnesses that may result from substance abuse include delirium and mood disorder.

After continued use of drugs, people may become addicted to them. This drug dependence can be psychological, physical, or both. People who use such drugs as alcohol and heroin may develop withdrawal symptoms if they stop using them. Typical withdrawal symptoms include nausea, vomiting, seizures, dizziness, and fever.

Causes of mental illness

Mental illnesses have various causes. Some mental illnesses are due to physical changes in the brain resulting from illness or injury. Chemical imbalances in the brain may cause other mental illnesses. Genetic factors and psychological and social factors also may play important roles in certain mental illnesses. Most researchers believe that the majority of mental disorders result from a combination of two or more causes.

Physical changes in the brain may cause a number of severe mental disorders, including delirium and dementia. Brain damage can result from head injuries, infections, or inherited defects. Diseases that damage or destroy brain tissue include encephalitis, meningitis, and brain tumors.

Chemical imbalances in the brain may also trigger mental illnesses, particularly schizophrenia, mood disorders, and some of the anxiety disorders. These imbalances occur when brain processes involving chemicals called *neurotransmitters* develop a malfunction. Important neurotransmitters include dopamine, serotonin, norepinepherine, gamma-amino-butyric acid, and glutamate. Neurotransmitters act as chemical messengers and enable nerve cells in the brain to communicate with one another. People with schizophrenia may have an ab-

normal amount of dopamine or an imbalance between dopamine and serotonin. Researchers believe that these and other neurotransmitters also play a role in mania, depression, anxiety disorders, and personality disorders.

Genetic factors. Research has shown that schizophrenia and mood disorders sometimes run in families. This evidence indicates that children who inherit certain genes from their parents may develop these mental illnesses. These genes probably control the production of chemicals in the brain or the way nerve cells form connections with one another in the brain. The disorder may not occur, however, unless certain environmental conditions are also present. Thus, a variety of factors may determine whether a person with an inherited tendency will actually become mentally ill.

Social and psychological factors that may increase the probability that a person will have a mental illness include early life experiences and various types of stress. Early life experiences, such as the loss of a parent, may affect an individual's ability to adapt to changes or to recover from painful events. Some common stresses that may contribute to the development of mental illness include difficulties in school or at work, poor health, financial problems, or family responsibilities.

Treatment of mental illness

Most people with mental illness require specialized treatment from mental health professionals, such as psychiatrists, psychologists, psychiatric social workers, or psychiatric nurses. Psychiatrists have an M.D. degree and advanced training in the treatment of mental illness. Psychologists have a doctor's or master's degree and may have practical clinical training that qualifies them to perform treatment. Most other mental health professionals have a bachelor's or master's degree and specialized training in counseling or rehabilitation.

Mental health professionals use a number of treatments for mental illness. The two main types of treatments are (1) somatic therapy and (2) psychotherapy. Most patients do not require inpatient hospital care and can be treated within their home community as outpatients. Treatment for extremely severe mental disorders, however, may require hospitalization.

Somatic therapy usually involves the use of medications. These medications provide the foundation for the treatment of severe mental illnesses. Most of them work by changing the balances of the brain's neurotransmitters. Another form of somatic therapy is *electroconvulsive therapy,* which involves passing an electric current through the brain. Both treatment with medications and electroconvulsive therapy must be administered by mental health professionals with medical training, usually psychiatrists.

Medication treatment. Since 1950, scientists have developed a number of medications that have proved extremely successful in the treatment of certain mental disorders. Psychiatrists use *heterocyclic antidepressants* and *selective serotonin reuptake inhibitors* (SSRI's) to treat patients with severe depression. In most cases, these medications restore the depressed patient to a normal level of functioning.

Lithium carbonate is the most effective drug for patients who suffer from bipolar disorder. It reduces the frequency and severity of both the manic and depressive periods and, in some cases, eliminates them entirely.

Medications called *antianxiety drugs* help relieve the tension caused by anxiety disorders. Increasingly, SSRI's are also used in the treatment of anxiety disorders and some personality disorders.

Psychiatrists use *antipsychotic drugs* to treat schizophrenia. These medications help relieve certain positive symptoms of schizophrenia, such as hallucinations and delusions. However, most antipsychotic drugs prove less effective in the treatment of negative symptoms.

The medications used to treat mental disorders may have side effects. Drowsiness may accompany the use of antianxiety drugs, and antipsychotic drugs may cause restlessness and muscle spasms. Some antidepressants may produce drowsiness and weight gain. Medication treatment may be discontinued after the symptoms of the disorder have diminished or stopped. In some cases, however, the symptoms then return, and the patient must resume taking medication.

Electroconvulsive therapy (ECT) is used primarily for the treatment of severe depression. Psychiatrists usually use it to treat hospitalized patients who remain depressed and suicidal in spite of medication treatment and psychotherapy. In most cases, ECT shortens the period of depression, but the patient must often take medication for some period of time after ECT treatment to reduce the risk of relapse.

An ECT treatment consists of passing an electric current through the patient's brain for a fraction of a second. Prior to treatment, the patient is given anesthesia and a drug that prevents convulsions. Typically, a patient receives such treatments two to three times a week, with a total of 6 to 10 treatments. After treatment, the patient experiences temporary amnesia and confusion. Mild problems with memory may persist for several months. ECT has aroused controversy due to concern about its side effects, but most psychiatrists believe it is an effective form of treatment for severe depression.

Psychotherapy is a form of treatment that uses psychological methods. For example, a patient in psychotherapy might try to achieve insight into unconscious thoughts or to learn more adaptive ways of responding or behaving. Psychotherapy may be used alone or in conjunction with medication treatment. The chief kinds of psychotherapy include (1) psychodynamic, (2) behavioral, (3) cognitive, (4) supportive, (5) group, (6) rehabilitative, and (7) play.

Psychodynamic psychotherapy is based on the theory that symptoms of mental illness result from conflicts between conscious and unconscious forces in the mind. The best-known form of psychodynamic therapy is called *psychoanalysis.* Psychoanalysts try to make their patients aware of unconscious mental conflicts and help them find ways to resolve these conflicts. Many analysts use a method called *free association,* in which the patient talks about anything that comes to mind. A psychoanalyst may also explore dreams and childhood memories, which can provide insight into unconscious thoughts and feelings.

Behavioral therapy concentrates on relieving current symptoms of the patient's mental illness without trying to understand unconscious conflicts. Behavioral thera-

pists help patients develop appropriate behavior through such methods as rewarding desirable responses and ignoring undesirable ones.

Cognitive therapy focuses on teaching patients how to retrain their thinking patterns. Cognitive therapists help patients to eliminate negative and undesirable thoughts and to improve self-esteem.

Supportive psychotherapy focuses on recent events and personal relationships in the patient's life. The patient and the therapist work as a team to solve problems. Supportive therapists provide reassurance and try to help patients appreciate and accept themselves.

Group therapy is conducted with a group of people, usually from 4 to 12. A therapist leads and guides the group. Many patients learn about their own problems by sharing experiences with people who have similar conflicts. The group members also encourage and support one another during times of personal stress.

Rehabilitative therapy focuses on teaching patients new skills and abilities. Patients with severe mental illnesses may need help in learning to deal with practical aspects of daily living, such as finding work, obtaining adequate housing, or managing finances. Social workers and rehabilitation counselors generally provide this type of therapy. It usually is offered in a community setting, such as a community mental health center.

Play therapy is used in treating mentally disturbed children. A therapist gives the child dolls and other toys and asks the youngster to tell a story about them. The child generally uses the toys to act out personal conflicts. The therapist then helps the young patient relate these play actions to his or her own situation.

Treatment settings. Mental health professionals usually provide treatment within the patient's home community. Hospitalization may be required, however, for those who need intensive medical attention or who might harm themselves or others. For example, patients whose symptoms include suicidal or violent behavior may require hospitalization.

University of Iowa Hospitals and Clinics

Rehabilitative therapy teaches new skills and abilities to patients with severe mental illnesses. Such therapy can help patients readapt to everyday situations and activities. In this photograph, three rehabilitation therapists practice basic techniques used in teaching how to cook a meal.

In a hospital setting, the medical staff can carefully monitor medication treatment. Furthermore, patients can begin rehabilitative programs that help them deal with the psychological and social consequences of their illnesses. In the past, patients with severe mental illnesses were hospitalized for long periods of time. But today, medications and ECT provide effective treatments for many of these disorders. As a result, most patients remain in the hospital for only a few days or weeks.

Community treatment programs developed as a complement to hospitalization treatment for the severely mentally ill. Types of community-based programs include vocational rehabilitation, day hospital programs, and group homes in which patients reside together. Rehabilitation counselors, social workers, psychologists, or psychiatrists usually provide community treatment.

Many areas do not have an adequate number of community treatment programs. This has contributed to an increase in the number of homeless mentally ill people. Mental health professionals working at community centers try to help the homeless mentally ill find food and shelter and readapt to life in a community.

History

Early attitudes. Prehistoric peoples apparently believed mental illnesses were caused by evil spirits that possessed the body. They may also have believed that drilling a hole into the person's skull would release the evil spirits. Scientists have found fossils of drilled skulls that date back as far as 10,000 years.

About 400 B.C., the Greek physician Hippocrates stated that mental disorders resulted from an imbalance of four body fluids: blood, phlegm, yellow bile, and black bile. For example, depression supposedly resulted from an excess of black bile. The ancient Greek name for this fluid, *melan chole,* is the origin of the word *melancholy,* which means *sadness.*

During the Middle Ages, a belief in witchcraft spread throughout Europe. Many people with mental illness were considered to be witches and were killed by burning, hanging, or drowning. Mentally ill people were also put in prisons or in government welfare institutions called *poorhouses.*

During the 1500's, many European nations built special institutions to separate the mentally ill from the rest of society. One of the most famous of these institutions was St. Mary of Bethlehem in London, which was widely known as *Bedlam.* The inmates there suffered from unsanitary conditions, beatings, and other harsh treatment. Today, the word *bedlam* means *uproar* and *confusion.*

Humane treatment of mentally ill people gained importance in the late 1700's. During that period, Philippe Pinel, a French physician, and William Tuke, a British merchant, worked to improve the conditions of mental institutions in their countries. Through their efforts, many mental hospitals introduced treatment programs that included fresh air and pleasant surroundings.

During the early 1800's, American physician Benjamin Rush incorporated the ideas of Pinel and Tuke in treating mentally ill patients at Pennsylvania Hospital in Philadelphia. Dorothea Dix, an American schoolteacher, began visiting mental hospitals throughout North America and Europe in the mid-1800's. She described the miserable conditions in these hospitals to state legislators and

Painting (mid-1800's) by Charles Muller. The Bettmann Archive

Humane treatment of mentally ill people gained importance in the late 1700's. This painting shows Philippe Pinel, a French physician of that period, pointing and demanding the removal of chains from mentally ill inmates of a hospital in Paris. Through Pinel's efforts, many hospitals introduced more humane treatment programs that included fresh air, exercise, and pleasant surroundings.

persuaded them to pass laws providing state funds for mental institutions.

Medical approaches to mental illness were first practiced in ancient Greece and Rome and again became standard practice in the late 1800's in Europe. German psychiatrist Emil Kraepelin presented a system of diagnosing and classifying mental disorders in 1883. His study of mental disorders and changes in the brain also advanced the search for the causes of mental illness.

In the early 1900's, Austrian psychiatrist Sigmund Freud introduced the theory that forces in the unconscious mind strongly influence an individual's personality and behavior. Freud also suggested that conflicts during early childhood affect the development of the unconscious. These theories became the basis for psychoanalysis and other forms of psychotherapy.

Recent developments. During the 1950's, the discovery of effective medication treatments led to a reduction in the number of patients in hospitals and state institutions built for the care of the mentally ill. In 1956, for the first time, the number of patients discharged from public mental hospitals in the United States exceeded the number admitted. Many communities, however, lacked adequate services and facilities to help mentally ill people readjust to living independently.

The Community Mental Health Centers Construction Act of 1963 provided funding for the development of community mental health centers throughout the United States. Although this act led to improved community services, it failed to ensure that the nation's health care system would provide treatment for mental illnesses equal to that provided for physical illnesses. As a result, many people with mental illnesses still cannot obtain or afford adequate treatment.

Mental health professionals, patients, and family members have formed organizations committed to improving public understanding of mental illness. The National Alliance for the Mentally Ill, one of the earliest of these groups, was established in 1979. In the late 1900's, many scientists began to study the living brain with new techniques, including *positron emission tomography* (PET) and *magnetic resonance imaging* (MRI). Images created with these technologies have shown that many mental illnesses involve problems in brain development, structure, or function.

- C. Treatment settings

IV. History

Questions

How did prehistoric peoples treat mental illnesses?
What is mania? How does it differ from depression?
What drugs do psychiatrists use to relieve anxiety? Schizophrenia? Manic-depressive disorder?
What are somatoform disorders?
What is supportive therapy?
How is electroconvulsive therapy used in treating mental disorders?
What is an *obsession?* A *compulsion?*
What is rehabilitative therapy?
How does psychoanalysis help patients understand their mental disorders?
What theories did Sigmund Freud introduce that led to the development of psychotherapy?

Feldman, Marc D., and others. *Stranger Than Fiction: When Our Minds Betray Us.* Am. Psychiatric Pr., 1998.

Mental retardation is a condition in which people have substantial limitations in their intellectual abilities. People with mental retardation score significantly below average on tests designed to measure intelligence. As a result of their intellectual limits, people with retardation experience difficulties in daily activities such as learning, working, and caring for themselves. They also have difficulty with such social skills as understanding other people's behavior or communicating thoughts and feelings.

To be considered mentally retarded, people must show signs of the condition before they reach 18 years of age. The most common symptom of retardation is a delay in achieving milestones of development. Many children with severe mental retardation fail to sit up or walk at the usual age for these accomplishments. Children with less severe retardation may be slow in learning to talk. Mild retardation may escape detection until a child starts school and has trouble learning.

Physicians and social workers once advised parents of children with mental retardation to place them in residential institutions. Experts now believe that living in a community is a better arrangement for all but the most seriously retarded. People with retardation and their families need varying levels of support services to help them live successfully in a community.

Diagnosis of mental retardation first requires determining that a person has a serious intellectual impairment. The best available—but still imperfect and inexact—means for measuring intelligence is a test called an IQ test. IQ tests assign an approximate numerical value to intelligence, and people of average ability score from about 90 to 110. People with mental retardation score below about 70 to 75. For a discussion of IQ tests and their limitations, see the article **Intelligence quotient**.

No IQ test score alone is a sufficient basis for a diagnosis of mental retardation. The score must be confirmed by expert evaluation of an individual's ability to perform daily activities and to function in everyday situations. There are four broad categories of mental retardation based on approximate IQ: (1) mild, (2) moderate, (3) severe, and (4) profound.

People with mild retardation form the largest group. These people have IQ's from about the low 50's to the low 70's. Many people with mild retardation can master reading and other schoolwork up to about the sixth-grade level. Most attend some special education classes and some regular classes. Many adults with mild mental retardation and good social skills can live with minimal supervision and work at jobs suited to their abilities.

People with moderate retardation have IQ's from about 40 to the low 50's. Educational goals for moderately retarded children focus on teaching them to care for themselves and other practical skills. Some can learn a little reading and writing. In some cases, adults with moderate retardation can work at suitable jobs at home or in special workshops.

People with severe retardation have IQ's from about the mid-20's to the high 30's. Training for them emphasizes learning to care for themselves and developing language and social skills. Individuals with severe mental retardation require close supervision throughout life.

People with profound retardation have IQ's below about 25. They remain at about the mental age of a baby or toddler. Their abilities to talk or care for themselves are usually limited. People with the most profound mental retardation need constant care to survive.

Causes. Mental retardation can result from any factor that hinders healthy brain development. In many cases, doctors cannot identify any single cause for the condition. Factors involved in mental retardation fall into the broad categories of (1) genetic and (2) environmental.

Genetic factors involve faulty chemical instructions in *genes,* the hereditary material in every cell. In human cells, genes are carried on 46 microscopic threads called *chromosomes* that are arranged in 23 pairs. Scientists have made great progress in learning how genes function. Some genetic errors cause mental retardation. In some cases, such errors are inherited. Others occur spontaneously for unknown reasons.

One common genetic cause of retardation is a disorder called Down syndrome, in which people have an entire extra chromosome, for a total of 47 (see **Down syndrome**). Another common genetic factor is called *fragile-X syndrome.* This condition involves an abnormality in the X chromosome, one of the chromosomes that determines a person's sex.

Many less common genetic factors affect genes that control a particular chemical pathway in the body. One such condition is phenylketonuria (pronounced *FEHN uhl KEE tuh NYUR ee uh,* often abbreviated PKU). People with PKU cannot process one of the subunits called *amino acids* in proteins. This amino acid builds up and leads to mental retardation if their diet is not controlled.

Environmental factors include a wide variety of influences that can affect brain development before, during, or after birth. During pregnancy, a woman's general health and nutrition greatly affect her unborn baby. Consumption of alcohol during pregnancy can lead to a condition in the baby called *fetal alcohol syndrome.* This syndrome causes many serious health problems, including mental retardation. Use of prescription, nonprescription, or illegal drugs can also harm a developing baby's brain. Exposure before birth to certain infections, including rubella (also called German measles) and HIV, can also cause retardation.

Events at birth can also harm the brain. Premature birth, injury during delivery, and failure of the newborn to breathe properly can all lead to retardation. During childhood, retardation can result from such causes as

brain infections, head injuries, prolonged high fevers, or lead poisoning.

Prevention. Good health habits and professional medical care during pregnancy can prevent many cases of mental retardation. Skilled delivery and care of sick or premature infants also help avoid some cases. Damage resulting from PKU and a few other disorders can be controlled after birth by a special diet or medication.

Some couples know that such factors as their age, family history, or ethnic background increase their risk of having children with certain genetic conditions. In some cases, genetic tests are available to determine if the parents or the unborn baby carry damaged genes. Some couples decide to have such tests and take the results into account in planning or continuing a pregnancy. See **Genetic counseling.**

Treatment of mental retardation focuses on identifying each individual's strengths and limitations and devising approaches that encourage the greatest possible intellectual and social development. One of the key parts of treatment consists of appropriate education or training. In the United States and many other countries, it is the legal right of every school-age child, no matter how seriously retarded, to have the opportunity to learn to function to the best of his or her ability. In some cases, training can begin in infancy. It may continue until the individual is well established in an adult role.

As children with retardation grow up, their education tends to center increasingly on the skills they will need as adults. Many adults with mild retardation are able to work and live with some independence. Mildly retarded adults who cannot work independently and some adults with moderate to severe mental retardation may work in a *sheltered workshop,* a center that employs people with disabilities. Most such individuals live with their families or in group homes in the community. Only people with the most severe mental retardation, who require constant care, are likely to live permanently in institutions. Marianne Schuelein

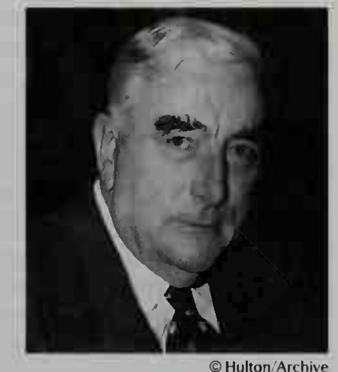
Menthol, *MEHN thahl,* is a soft, white substance with a mint odor and a fresh, cool taste. It is widely used as an ingredient in cough and cold medicines, perfumes, and cigarettes. Menthol is found in oil of the leaves of the peppermint plant.

Menthol is a *differential anesthetic*—that is, a substance that causes the loss of some sensations. Therefore, it can be used as a salve that reduces itching. But menthol also stimulates the *receptor* (receiver) cells in the skin that normally respond to cold. Thus, it gives a sensation of coolness unrelated to body temperature. Menthol's chemical formula is $C_{10}H_{20}O$. Dorothy M. Feigl

Mentor was the elderly friend and adviser of Odysseus, the hero of the *Odyssey,* an ancient Greek epic. Before Odysseus (Ulysses in Latin) went to fight in the Trojan War, he made Mentor the guardian of his son, Telemachus. In Mentor's shape, the goddess Athena helped Telemachus search for Odysseus. Today, the word *mentor* means a wise, faithful counselor.

Cynthia W. Shelmerdine



Menuhin, *MEHN yoo ihn,* **Yehudi,** *yuh HOO dee* (1916-1999), was an American-born violinist who had spectacular success as a child prodigy. He promoted the works of contemporary composers and revived neglected, but valuable, music of the past. He combined the classical musical style of his early training with jazz and with the music of India and other countries.

Menuhin was born on April 22, 1916, in New York City. At the age of 7, he appeared as a violin soloist with the San Francisco Orchestra. Menuhin was active in training young musicians, most significantly at a school in Surrey, England, he founded in 1963. He also gained acclaim as a conductor. His essays and speeches on music and other subjects were collected in *Theme and Variations* (1972). He also wrote an autobiography, *Unfinished Journey* (1977), revised as *Unfinished Journey: Twenty Years Later* (1997). Menuhin became a British citizen in 1985, was knighted that year, and was made a baron in 1993. Stephen Clapp

Menzies, *MEHN zeez,* **Sir Robert Gordon** (1894-1978), served as prime minister of Australia from 1939 to 1941 and from 1949 to 1966. He held the post longer than any other prime minister in Australian history.

Menzies was born on Dec. 20, 1894, in Jeparit, near Dimboola, in the British colony (later the Australian state) of Victoria. He received a law degree from the University of Melbourne in 1916 and became a *barrister* (lawyer) in 1918. In 1928, he was elected to the Legislative Council, the upper house of the Victorian parliament.

In 1934, Menzies was elected to the Australian House of Representatives. He kept his seat in the House until he retired from politics in 1966. From 1934 to 1939, he served as attorney general in the United Australia Party (UAP) government of Prime Minister Joseph Lyons. Lyons died in April 1939. The UAP then elected Menzies as its leader, and he became prime minister.

© Hulton/Archive

Robert Menzies

After World War II started in September 1939, Menzies's government came under criticism for not preparing Australia sufficiently for war. Some UAP members joined in the criticism. In 1941, Menzies resigned as prime minister and as leader of the UAP.

Menzies again was elected leader of the UAP in 1943. The next year, he led an effort to combine forces that opposed the ruling Australian Labor Party. A new opposition party, the Liberal Party of Australia, emerged from this effort. The Liberal Party favored less government regulation of the economy. The Liberals came to power in 1949, and Menzies again became prime minister.

The steady growth of the Australian economy benefited Menzies's second period as prime minister. He increased government support of higher education. In the early 1950's, Menzies supported a failed referendum to ban Australia's Communist Party. He sent Australian

troops to fight in the Korean War (1950-1953) and the Vietnam War (1957-1975). Queen Elizabeth II of the United Kingdom knighted Menzies in 1963. Judith Brett

Mephistopheles, *MEHF uh STAHF uh leez,* is the Devil in a German legend about a magician named Faust. In an anonymously written book called *The History of Johann Faust* (1587), Faust sold his soul to Mephistopheles in return for the Devil's services for 24 years. The name *Mephistopheles* may come from three Greek words meaning *not loving the light* or, possibly, from the Hebrew *mephiz* (destroyer) and *tophel* (liar).

In Johann von Goethe's drama *Faust* (1808, 1832), Mephistopheles is a clever evil spirit who is "part of that force, which would do ever evil, and does ever good." The Devil loses in the end, because the troubles he causes only help humanity to find wisdom and grace. Mephistopheles also appears in the operas *Faust* (1859) by Charles Gounod and *Mefistofele* (1868) by Arrigo Boito, and in Christopher Marlowe's play *The Tragical History of Doctor Faustus* (written about 1588).

Klaus L. Berghahn

Mercantilism, *MUR kuhn tih LIHZ uhm,* was an economic system followed by England, France, and other major trading nations from the 1500's to the late 1700's. Under this system, a nation's government strictly regulated economic affairs to enrich its treasury, especially by ensuring that exports exceeded imports.

Mercantilism was based on two beliefs. First, mercantilists judged a nation's wealth by its stock of gold and silver, rather than by standards of living or other measurements. Second, the mercantilists believed the world had a limited supply of wealth, and so one country could grow rich only at the expense of another.

According to the mercantilists, a nation that did not have gold or silver mines had to rely on foreign trade to become rich. They called for an excess of exports over imports, a situation they termed a *favorable balance of trade.* At that time, gold served as the chief means of settling international debts. A nation that exported more than it imported could collect the difference in gold from the importing countries.

To maintain a favorable balance of trade, mercantilist governments enacted high tariffs and other restrictions on imports. The governments also strongly encouraged the growth of domestic industries. Many nations sought overseas colonies, which served as markets for exports and as sources of raw materials. Mercantilist governments also encouraged population growth, because a large population provided a supply of labor and a market for industrial products. Some nations prohibited the sale of gold and other precious metals to foreigners.

During the late 1700's, the mercantilist systems of many countries were gradually replaced by a policy called *laissez faire.* Under laissez faire, the government played a limited role in economic affairs.

Today, the term *mercantilism* is sometimes used to describe policies that protect domestic industries from foreign competition. In addition, mercantilist efforts to plan economic activity resemble government planning under Communism and socialism. But there are many differences between mercantilism and a socialist or Communist system. Richard C. Wiles

Mercator, *muhr KAY tuhr,* **Gerardus,** *juhr AHR duhs* (1512-1594), was a Flemish geographer who became the leading mapmaker of the 1500's. He won lasting fame because of his world map of 1569. It introduced a new way of showing the roughly ball-shaped earth on a flat sheet of paper. This method, called the Mercator projection, proved ideal for navigation. It is still used today.

On a map using the Mercator projection, the *meridians* (lines of longitude) and the *parallels* (lines of latitude) appear as straight lines that cross at right angles. The straight lines, plus the aid of a compass, help navigators plot accurate routes. However, many geographical features on this kind of map are exaggerated in size. See **Map** (The Mercator projection).

Mercator was born on March 5, 1512, in Rupelmonde, Flanders (now Belgium). His given name was Gerard Kremer, but he adopted the Latin form of this name. Mercator studied at the University of Louvain. Later, he made globes and navigation instruments for Holy Roman Emperor Charles V. He also produced a collection of maps titled *Atlas.* This title marked the first use of the word *atlas* to describe a collection of maps. John Noble Wilford

Mercenary, *MUR suh NEHR ee,* is a person who serves for pay in the armed forces of a foreign country. Most men and women who become mercenaries do so to make money. They may also become a mercenary because they love war and adventure.

In ancient times, Persia, Greece, and Rome used mercenaries. Mercenaries were most common from about 1100 to 1500. During that time, many rulers hired trained professional soldiers to protect their states. Some rulers made money by hiring out their mercenary armies to other states.

During the Revolutionary War in America (1775-1783), Britain hired German soldiers called *Hessians* to fight the American colonists. Such military heroes as Casimir Pulaski of Poland and Baron von Steuben of Prussia—both of whom helped the colonists—are also technically considered mercenaries.

The rise of national armies largely ended the need for mercenaries. Today, a few countries in developing areas use mercenaries instead of or as part of their military forces. The French Foreign Legion is a well-known modern mercenary force. Richard A. Sauers

Mercer, Johnny (1909-1976), was one of the greatest lyric writers in the history of American popular music. He collaborated with such composers as Harold Arlen, Hoagy Carmichael, Jerome Kern, Henry Mancini, and Harry Warren. He wrote lyrics to more than 1,000 songs, the best noted for their polished wit. Mercer composed the words to the hit songs "Goody Goody" (1936), "Fools Rush In" (1940), "Blues in the Night" (1941), "That Old Black Magic" (1942), "One for My Baby" (1943), "Ac-cent-tchu-ate the Positive" (1944), "Laura" (1945), "Come Rain or Come Shine" (1946), and "Satin Doll" (1958).

Mercer also wrote lyrics for the stage and motion pictures. He wrote the music and lyrics for the Broadway show *Top Banana* (1951) and the lyrics to the score for the musical *St. Louis Woman* (1946), among other shows. Mercer won four Academy Awards as lyricist for the songs "On the Atchison, Topeka and the Santa Fe" (1946), "In the Cool, Cool, Cool of the Evening" (1951), "Moon River" (1961), and "The Days of Wine and Roses" (1962).

John Herndon Mercer was born on Nov. 18, 1909, in Savannah, Georgia. He was a cofounder of Capitol Records in 1942 and made many best-selling recordings for the company. Paul F. Wells

Merchandising. See Marketing.

Merchant. See Trade (Early trade).

Merchant marine is a fleet made up of a nation's commercial ships and the men and women who operate them. It includes both cargo and passenger ships.

The importance of a country's merchant marine is measured by its *gross tonnage,* rather than by the number of ships. Gross tonnage is the total space within the hull and enclosed deck space on a ship. Each 100 cubic feet of space in a ship equals 1 gross ton.

Technically, the world's largest merchant fleet is registered under the flag of Panama. But Panamanians own only a few of these ships. Many shipowners from other countries register their vessels in such countries as Panama, Liberia, or the Bahamas because taxes are lower there. Other countries with large merchant marines include Cyprus, Greece, Malta, and Norway. For a list of the world's leading merchant fleets, see **Ship** (table).

The United States merchant marine. The American Colonies had a large merchant fleet before the Revolutionary War in America started in 1775. By 1800, America's merchant fleet ranked second in the world only to the British fleet. But much United States shipping was destroyed during the American Civil War (1861-1865). Most of the remaining ships became obsolete when steel hulls and steam power were developed.

The United States Shipping Board was created in 1916. It improved the merchant marine by building and purchasing ships and regulating shipping. Since 1950, the Maritime Administration has assisted the merchant marine through programs that help U.S. shippers operate modern ships (see **Maritime Administration**).

Careers in the merchant marine. One way to become an officer in the United States merchant marine is to gain admission to the United States Merchant Marine Academy in Kings Point, New York. See **United States Merchant Marine Academy**.

A person can also earn an officer's license by studying at a state nautical school. But only a few states have these schools. Courses needed for an officer's license generally require three or four years of study. Seamen can also earn an officer's license by spending three years at sea, working either on the deck or in the engine room to advance in unlicensed ratings. Then they must pass the licensed officer's examination. Young people may obtain unlicensed positions aboard ship if they can get seamen's certificates from the Coast Guard. Wages are set by contracts between shipping companies and maritime unions. Officers and seamen in the British merchant fleet receive their training by studying on training ships or enrolling in nautical schools for two or three years of study. Critically reviewed by the Maritime Administration

Merchant Marine Academy. See United States Merchant Marine Academy.

Mercier, *mehr SYAY,* **Désiré,** *day zee RAY,* **Joseph Cardinal** (1851-1926), was a Belgian cardinal of the Roman Catholic Church who became a national hero during World War I (1914-1918). During the war, German troops occupied most of Belgium. Mercier spoke out against the injustices he saw in the occupation and tried to rally the morale of his fellow Belgians. Through his preaching and *pastoral letters* (statements on important issues for distribution to church members), he became a center of Belgian resistance. Mercier's patriotic activities won great respect in Belgium and other countries fighting Germany.

Mercier was born on Nov. 21, 1851, in Braine-l'Alleud, Belgium. He was ordained a priest in 1874. He became a professor of philosophy at the Roman Catholic seminary in Malines in 1877 and at the University of Louvain in 1882. In 1889, Mercier founded and served as the first president of an institute of philosophy at Louvain. There, in 1892, he installed one of the first laboratories of experimental psychology in a European university. In 1906, Mercier was appointed archbishop of Malines. Pope Saint Pius X named him a cardinal in 1907.

Mercosur, *MEHR koh soor,* is an association of several South American countries that work to increase trade among themselves. Argentina, Brazil, Paraguay, and Uruguay founded Mercosur in 1991. Chile joined as an associate member in 1996, and Bolivia became an associate member in 1997. Today, Mercosur is one of the world's largest trade blocs. Its name in Spanish is Mercado Común del Sur (Southern Common Market). In Portuguese, the language of Brazil, the group is known as Mercado Comum do Sul (Mercosul). Headquarters are in Montevideo, Uruguay.

Since its founding, Mercosur has lowered tariffs, import quotas, and other trade barriers among member and associate member nations. In 1995, the four full members adopted a common external tariff for many imports from countries outside the association. Associate members do not share the common external tariff. Other goals include the establishment of standard trade rules and procedures and the coordination of economic policies among members. Eliza J. Willis

Mercury, a silver-colored metal, is one of the chemical elements. Unlike any other metal, mercury is a liquid at room temperature. It flows so easily and rapidly that it is sometimes called *quicksilver.* No one knows who discovered mercury, but the ancient Chinese, Egyptians, Greeks, Hindus, and Romans knew about the metal. It was named for the swift messenger of the gods in Roman mythology.

Mercury is used in some types of thermometers and barometers and in other instruments. Mercury compounds are used in agriculture and industry. These compounds once were widely used in such common products as house paints and paper. As a result, mercury became widespread in the environment. Mercury, however, is extremely poisonous and can cause illness or death. After many people realized its dangers, industries and government began trying to reduce the amount of mercury reaching the environment.

Mercury has the chemical symbol Hg. Its atomic weight is 200.59 and its atomic number is 80. Mercury melts at −38.87 °C and boils at 356.58 °C.

Uses. Mercury has many *properties* (qualities) that make it useful. For example, mercury expands and contracts evenly when heated or cooled. It also remains liquid over a wide range of temperatures and does not stick to glass. These properties have prompted its use in thermometers.

Mercury conducts electric current and is used in

WORLD BOOK photo

Mercury is a silver-colored liquid at room temperature, *right.* Most mercury comes from the ore cinnabar, *left.*

some electric switches and relays to make them operate silently and efficiently. Industrial chemical manufacturers use mercury in *electrolysis cells* to change substances with electric energy. Mercury vapor, used in fluorescent lamps, gives off light when electric current passes through it.

Various *alloys* (mixtures of metals) containing mercury have many uses. Mercury alloys are called *amalgams.* They include silver amalgam, a mixture of silver and mercury that dentists use to fill cavities in teeth. Many dry cell batteries contain amalgams of zinc and cadmium to prevent impurities from shortening the life of the battery.

Sources. Mercury is less abundant in the earth's crust than many other metals. However, because mercury deposits are quite concentrated, it is readily available. Most of the mercury used by people comes from an ore called *cinnabar.* To obtain pure mercury, refiners heat cinnabar in a flow of air. Oxygen in the air combines with sulfur in the ore, forming sulfur dioxide gas and leaving mercury behind.

Spain is the leading producer of mercury from ore. Other major producers include Algeria, China, Italy, Kyrgyzstan, Mexico, Slovakia, Ukraine, and the United States.

Compounds. Chemists divide mercury compounds into two groups: (1) *mercurous* or *mercury (I)* compounds, and (2) *mercuric* or *mercury (II)* compounds. Mercurous compounds include *mercurous chloride* (Hg_2Cl_2), also called *calomel,* and *mercurous sulfate* (Hg_2SO_4). Calomel is an antiseptic used to kill bacteria. Scientists use mercurous sulfate to speed up certain tests on organic compounds.

Mercuric compounds include *mercuric chloride* ($HgCl_2$), a powerful poison that surgeons once used to disinfect wounds. Mercuric chloride is also known as *corrosive sublimate* or *bichloride of mercury.* Most ammunition uses *mercuric fulminate* ($Hg[OCN]_2$) to set off its explosive. Paint manufacturers use *mercuric sulfide* (HgS) in making a red pigment called *vermilion.* Mercury batteries contain *mercuric oxide* (HgO). Several organic mercuric compounds have important medical uses. For example, some medicines called *diuretics,* which physicians use to treat kidney disease, contain these compounds. In addition, the antiseptic *Mercurochrome* is a mercuric compound.

Mercury in the environment is hazardous chiefly because its poisonous compounds have been found in plants and animals that people use for food. Scientists have discovered poisonous mercury compounds in such foods as eggs, fish, grain, and meat. Mercury acts as a *cumulative* poison—that is, the body has difficulty eliminating it. Thus, it may collect over a long time, eventually reaching dangerous levels.

Among the most dangerous mercury compounds are those containing *methyl mercury.* They can damage brain cells. In the mid-1950's, more than 100 Japanese were poisoned by fish that contained large amounts of methyl mercury. The mercury came from industrial wastes that had been dumped into the bay where the fish were caught. In the early 1970's, some tuna and swordfish sold in U.S. stores were found to contain dangerous amounts of mercury. The United States government recalled the fish from the stores and warned the public.

Government and industry are working to keep mercury out of the environment. In the early 1970's, the U.S. and Canadian governments began to prohibit industrial dumping of wastes containing mercury. Much mercury has been put into the environment in other ways. Mercury compounds were once used to prevent fungi from growing in lumber, paint, paper, and seeds, and to kill plant fungus diseases. Shipbuilders used paint containing mercury to prevent marine organisms from growing on the hulls of ships. In 1972, the U.S. government halted the use of mercury compounds for most of these purposes. Raymond E. Davis

Mercury is the planet nearest the sun. It has a diameter of 3,031 miles (4,878 kilometers), about two-fifths the earth's diameter. Mercury's mean distance from the sun is about 36 million miles (57.9 million kilometers), compared with 67,250,000 miles (108,230,000 kilometers) for Venus, the second closest planet.

Because of Mercury's size and nearness to the brightly shining sun, the planet is often hard to see from the earth without a telescope. At certain times of the year, Mercury can be seen low in the western sky just after sunset. At other times, it can be seen low in the eastern sky just before sunrise.

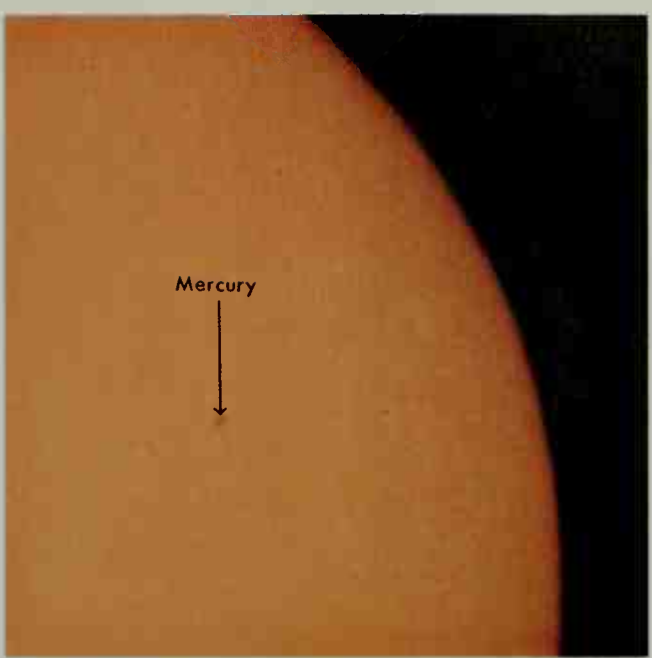
Orbit. Mercury travels around the sun in an *elliptical* (oval-shaped) orbit. The planet is about 28,600,000 miles (46 million kilometers) from the sun at its closest point, and about 43.4 million miles (69.8 million kilometers) from the sun at its farthest point. Mercury is about 57 million miles (91.7 million kilometers) from the earth at its closest approach.

Mercury moves around the sun faster than any other planet. The ancient Romans named it Mercury in honor

Hyron Spinrad, the contributor of this article, is Professor of Astronomy at the University of California, Berkeley.

of the swift messenger of their gods. Mercury travels about 30 miles (48 kilometers) per second, and goes around the sun once every 88 earth-days. The earth goes around the sun once every 365 days, or one year.

Rotation. As Mercury moves around the sun, it rotates on its *axis,* an imaginary line that runs through its center. The planet rotates once about every 59 earth-days—a rotation slower than that of any other planet except Venus. As a result of the planet's slow rotation on its axis and rapid movement around the sun, a day on Mercury—that is, the interval between one sunrise and the next—lasts 176 earth-days.



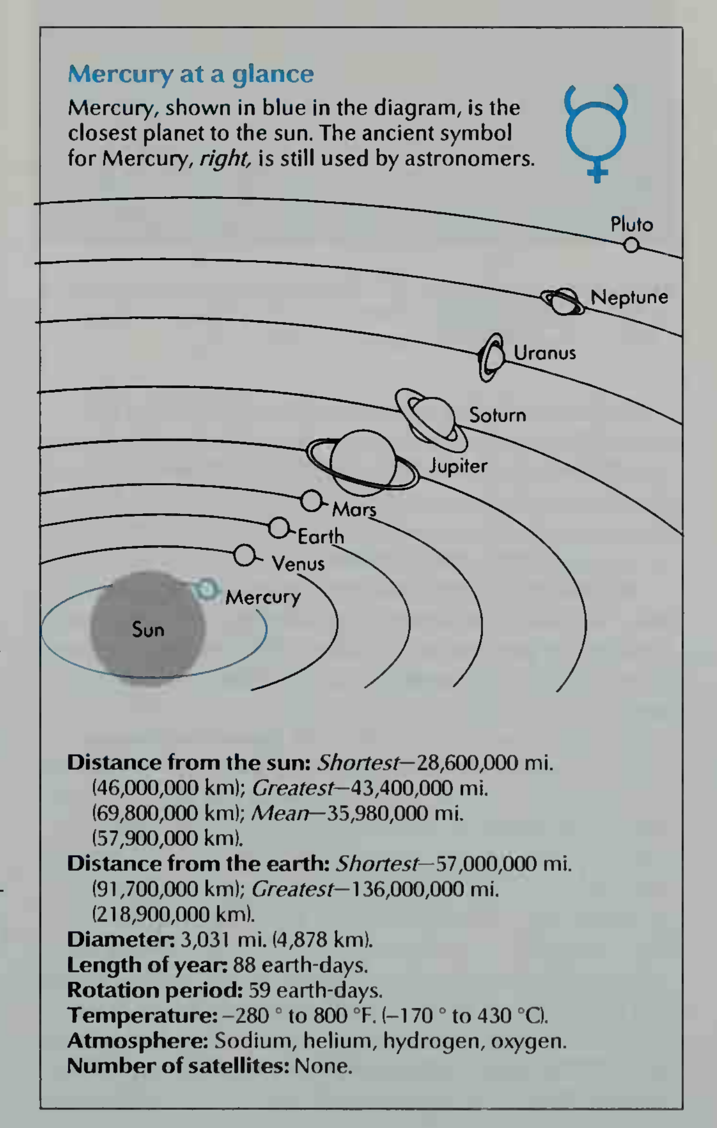
Until 1965, astronomers believed that Mercury rotated once every 88 earth-days, the same time the planet takes to go around the sun. If Mercury did this, the sun would seem to stand still in Mercury's sky. One side of the planet would always face the sun, and the other side would always be dark. In 1965, astronomers bounced radar beams off Mercury. The signals returning from one side of the planet differed from those from the other side. Using these beams, the astronomers measured the movement of the opposite sides and found that Mercury rotates once in about 59 days. The 59-day rotation period is two-thirds of the 88-day period that makes up a year on Mercury.

Phases. When viewed through a telescope, Mercury can be seen going through "changes" in shape and size. These apparent changes are called *phases,* and resemble those of the moon. They result from different parts of Mercury's sunlit side being visible from the earth at different times.

As Mercury and the earth travel around the sun, Mercury can be seen near the other side of the sun about every 116 days. At this point, almost all its sunlit area is visible from the earth. It looks like a bright, round spot with almost no visible marks. As Mercury moves around the sun toward the earth, less and less of its sunlit area can be seen. After about 36 days, only half its surface is visible. After another 22 days, it nears the same side of the sun as the earth, and only a thin sunlit area is visible. The amount of sunlit area that can be seen increases gradually after Mercury passes in front of the sun and begins moving away from the earth.

When Mercury is on the same side of the sun as the earth is, its dark side faces the earth. The planet is usually not visible at this point because Mercury and the earth orbit the sun at different angles. As a result, Mercury does not always pass directly between the earth and the sun. Sometimes Mercury is directly between the earth and the sun. When this occurs, every 3 to 13 years, the planet is in *transit* and can be seen as a black spot against the sun.

Surface and atmosphere. Mercury's surface appears to be much like that of the moon. It reflects approximately 6 percent of the sunlight it receives, about the same as the moon's surface reflects. Like the moon, Mercury is covered by a thin layer of minerals called *silicates* in the form of tiny particles. It also has broad, flat plains; steep cliffs; and many deep craters similar to those on the moon. Many astronomers believe the craters were formed by meteorites or small comets crashing into the planet. Mercury does not have enough atmosphere to slow down meteoroids and burn them up by friction.



Russ Kinne, Photo Researchers

Mercury appears as a tiny dot against the sun when it is directly between the sun and the earth. Mercury is so small and so near the sun that a telescope is needed to see it at this point.

Mercury at a glance

Mercury, shown in blue in the diagram, is the closest planet to the sun. The ancient symbol for Mercury, *right,* is still used by astronomers.

Distance from the sun: *Shortest*—28,600,000 mi. (46,000,000 km); *Greatest*—43,400,000 mi. (69,800,000 km); *Mean*—35,980,000 mi. (57,900,000 km).
Distance from the earth: *Shortest*—57,000,000 mi. (91,700,000 km); *Greatest*—136,000,000 mi. (218,900,000 km).
Diameter: 3,031 mi. (4,878 km).
Length of year: 88 earth-days.
Rotation period: 59 earth-days.
Temperature: −280 ° to 800 °F. (−170 ° to 430 °C).
Atmosphere: Sodium, helium, hydrogen, oxygen.
Number of satellites: None.

NASA

The planet Mercury was first photographed in detail on March 29, 1974, by the U.S. probe Mariner 10. The probe was about 130,000 miles (210,000 kilometers) from Mercury.

Mercury's interior appears to resemble that of the earth. Many scientists think the interiors of both planets consist largely of iron and other heavy elements. The discovery of a magnetic field around Mercury led some scientists to believe that the planet has a large core of liquid iron, just as the earth does.

Mercury is dry, extremely hot, and almost airless. The sun's rays are approximately seven times as strong on Mercury as they are on the earth. The sun also appears about 2 $\frac{1}{2}$ times as large in Mercury's sky as in the earth's.

Mercury does not have enough gases in its atmosphere to reduce the amount of heat and light it receives from the sun. The temperature on the planet may reach 800 °F (430 °C) during the day. But at night the temperature may drop as low as −280 °F (−170 °C). Because of the lack of atmosphere, Mercury's sky is black. Stars probably would be visible from the surface during the day.

Scans of Mercury made by earth-based radar indicate that craters at Mercury's poles contain water ice. The floors of the craters are permanently shielded from sunlight, so the temperature never gets high enough to melt the ice.

Mercury is surrounded by an extremely small amount of helium, hydrogen, oxygen, and sodium. This envelope of gases is so thin that the greatest possible *atmospheric pressure* (force exerted by the weight of gases) on Mercury would be about 0.00000000003 pound per square inch (0.000000000002 kilogram per square centimeter). The atmospheric pressure on the earth is about 14.7 pounds per square inch (1.03 kilograms per square centimeter).

The plant and animal life of the earth could not live on Mercury because of the lack of oxygen and the intense heat. Scientists doubt that the planet supports any form of life.

Density and mass. Mercury's *density* is slightly less than the earth's (see **Density**). That is, a portion of Mercury would weigh slightly less than an equal portion of the earth. Mercury is smaller than the earth and therefore has much less *mass* (see **Mass**). Mercury's smaller mass makes its force of gravity only about a third as strong as that of the earth. An object that weighs 100 pounds on the earth would weigh only about 38 pounds on Mercury.

Flights to Mercury. The United States Mariner 10 became the first and only spacecraft to reach Mercury. The remotely controlled spacecraft flew to within 460 miles (740 kilometers) of Mercury on March 29, 1974. It swept past the planet again on Sept. 24, 1974, and on March 16, 1975. During those flights, the spacecraft photographed portions of the surface of Mercury. It also detected Mercury's magnetic field.

Mariner 10 became the first spacecraft to study two planets. The probe photographed and made scientific measurements of Venus while traveling on its way to Mercury. As the probe flew near Venus, the planet's gravity pulled on the spacecraft, causing it to move faster. Thus, Mariner 10 reached Mercury in less time and by using less fuel than if it had flown directly from the earth.

In the future, space probes without crews may go into orbit around Mercury, crash into it, or land on it. Human exploration of the planet would be difficult because of the extreme temperatures that occur on its surface.

Mercury was the messenger of the gods and the god of roads and travel in Roman mythology. The ancient Romans also worshiped Mercury as the god of commerce, property, and wealth. The words *commerce, merchandise,* and *merchant* are related to his name. The Romans considered Mercury crafty and deceptive. They even saw him as a trickster or thief. Criminals regarded him as their protector. Because Mercury resembled the messenger god Hermes in Greek mythology, he took on many of Hermes's myths.

Mercury delivered his messages with miraculous speed because he wore winged sandals called *talaria.* He also wore a broad-brimmed winged hat called a

petasus and carried a winged staff. The Greeks called the staff a *kerykeion,* from the Greek word for *messenger.* In Latin, the language of the Romans, the word was changed to *caduceus.* Mercury's caduceus had two snakes curled around it. In ancient times, most messengers and travelers wore a hat similar to Mercury's petasus to protect them from the sun. Messengers also carried a staff to identify themselves so they could travel freely. Mercury later became associated with magic and science. His caduceus is frequently confused with the single-snake crutch of Aesculapius, who was the Roman god of healing.

Mercury was the son of Jupiter, the king of the gods, and Maia, a minor goddess. Artists portrayed Mercury as a handsome young man, with an expression of alertness and intelligence.

Meredith, George (1828-1909), was an English novelist and poet. He wrote his novels in a subtle poetic prose, rich in metaphor. His best-known novel, *The Ordeal of Richard Feverel* (1859), is the story of the harm done a young man who is sheltered by his father and educated at home. It is one of several novels written by Meredith in which a duel is fought over a woman. *The Egoist* (1879) and *Diana of the Crossways* (1885) show Meredith's support of the emancipation of women. The heroine exercises freedom of choice in love and marriage.

Meredith thought his poetry had more merit than his novels, and many scholars agree. His *Modern Love* (1862) is one of the finest poetic works of the Victorian Age. It is a long, beautifully written sequence of 16-line sonnets inspired by his unhappy marriage to his first wife, who deserted him. Meredith was born in Portsmouth. He worked for many years as a journalist and literary critic. Sharon Bassett

See also English literature (Later Victorian literature).

Meredith, James Howard (1933-), was the first African American to attend the University of Mississippi. He tried to register at the school in the fall of 1962. He was accompanied by federal marshals, but police and other state officials repeatedly barred his entrance. A large protest group that gathered on the campus rioted against Meredith and the marshals. Two people were killed. But Meredith succeeded in registering, and federal troops stayed on the campus to protect him until he graduated in 1963.

United Press Int.

James Meredith

In 1966, Meredith led a march in the South to encourage blacks to vote. A sniper shot him in Mississippi, but he recovered, and later completed the march.

Meredith was born in Kosciusko, Mississippi. He wrote the book *Three Years in Mississippi* (1966).

C. Eric Lincoln

Merganser, *muhr GAN suhr,* is the name of a group of ducks that eat fish. Mergansers have straight narrow bills for grasping their food. Their bills also have notched edges, which is the reason mergansers are sometimes called *sawbills.* Mergansers are found in many parts of the world. The *American, red-breasted,* and *hooded mergansers* live in North America.

WORLD BOOK illustration by Trevor Boyer, Linden Artist's Ltd.

The American merganser has a straight narrow bill hooked at the tip and notched at the edges. The bill helps it catch fish.

Mergansers have crests of feathers on their heads. The males are black and white, and the females are drab brown and gray. The American merganser has a glossy greenish-black head, a dark back, and white neck and sides. The red-breasted merganser is similar, but it has a cinnamon-red breast and a longer crest. The hooded merganser has a large black-and-white crest. All three species have white wing patches. Eric G. Bolen

Scientific classification. Mergansers belong to the family Anatidae. The scientific name for the American merganser is *Mergus merganser.* The red-breasted merganser is *M. serrator.* The hooded merganser is *Lophodytes cucullatus.*

Mergenthaler, *MUR guhn THAW luhr,* **Ottmar,** *AHT mahr* (1854-1899), invented the Linotype typesetting machine. Mergenthaler made a device with a keyboard that composed *matrices* (molds) for letters, and cast an entire line of type at once. He demonstrated and patented the Linotype in 1884. It was first used in 1886. Mergenthaler

was born in Württemberg, Germany, and came to the United States in 1872. See also **Linotype.**

Peter M. VanWingen

Merger is a combination of two or more independent businesses into a single corporation. A merger usually involves *acquisition,* one company absorbing one or more other companies. In a *friendly take-over,* the shareholders and directors of two or more independent firms agree to combine their firms. In a *hostile take-over,* an individual, group, or firm known as a *raider* acquires a sufficiently large portion of a company's stock to gain control or ownership of the company.

Mergers can occur in several ways. Usually, one firm buys the assets of another firm with cash or securities. Sometimes one company purchases the stock of another company by offering to pay a predetermined price for every share. Another way involves an exchange of stock between companies. In some cases, a buyer purchases a firm through an arrangement called a *leveraged buyout.* In this type of acquisition, the buyer borrows the needed funds and then repays the loan largely with money earned by running the company more efficiently than the previous owners.

There are a number of different types of mergers. A *horizontal merger,* for example, combines firms that produce the same product or service for the same market. A *market extensional merger* involves firms that produce the same good or service for different markets. A *vertical merger* joins a supplier and a user, such as a tire company and an automaker. Sometimes the merged business is not related to that of the acquiring firm, in which case the new business is called a *conglomerate.*

The main benefit of a merger is that it can help increase the efficiency of an organization. However, many mergers do not work out because the two firms cannot combine their resources effectively. In addition, some critics of horizontal mergers fear that the merged companies might gain significant control of an entire industry, eliminate competition, and raise prices.

Richard M. Hodgetts

Meridian. See **Greenwich Meridian; Longitude.**

Mérimée, *may ree MAY,* **Prosper,** *praws PAIR* (1803-1870), a French author, is best known for his *novelettes* (long short stories). One of them, "Carmen" (1845), was the source for Georges Bizet's opera of the same name (see **Opera** [*Carmen*]). Mérimée's other novelettes include "Mateo Falcone" (1829) and "Colomba" (1840), tales of violence in Corsica. In the fantastic tale "The Venus of Ille" (1837), the hero is apparently killed by a statue.

Mérimée was born in Paris. His first works were *Theatre of Clara Gazul* (1825), a group of plays; and *La Guzla* (1827), a book of ballads. He fooled the public by saying these works were translations. Mérimée wrote during the Romantic age, and his work has elements of both Romantic and Classical literature. It is Romantic in the violent passions it portrays, and in the strong personalities of its characters. Mérimée's work is Classical in its unemotional presentation, formal style, and its attention to detail.

In the 1850's, Mérimée worked to arouse French interest in Russia and its literature through his essays and translations. As inspector general of historic monuments, he was active in restoring and preserving important French monuments. Mérimée also wrote much history, in addition to his plays and fiction.

Thomas H. Goetz

Merlin was a magician and prophet who was an adviser to the legendary King Arthur. Various stories about Merlin appear in medieval literature. According to some narratives, Merlin educated Arthur as a youth. Merlin also helped establish the Round Table at which King Arthur's knights sat. He foresaw events of Arthur's reign, including the quest for the Holy Grail and the destruction of King Arthur's castle, Camelot. In addition, Merlin was said to have created the ancient British monument known as Stonehenge.

The story of Merlin probably originated in legends of a Celtic poet and prophet who lived in the 500's. The earliest detailed account of the Arthurian legends describes Merlin as a wizard and prophet whose father was a devil. In later stories, Merlin falls in love with Vivian, also known as the Lady of the Lake. She uses her magic to imprison him forever. Edmund Reiss

See also **Arthur, King.**

Mermaid was a mythical creature that lived in the sea. According to popular belief, mermaids were half human and half fish. They attracted mortal men by their beauty and their singing. They would sit and comb their golden hair. A magic cap lay beside them. They would slip the cap on the head of the man they wanted and take him away with them. A human being could live in the sea by wearing the magic cap. There were also mermen, who captured mortal maidens.

Mermen and mermaids are often found in art and poetry. Certain sea animals, such as the seal, the dolphin, and especially the manatee or sea cow, look a little like human beings from a distance. This similarity in appearance may explain the stories. See also **Sirenia.**

C. Scott Littleton

Merovingian dynasty, *MEHR uh VIHN jee uhn,* was a line of Frankish kings who conquered Gaul and surrounding lands beginning in A.D. 486 and ruled until 751. The Franks were Germanic peoples, and Gaul was a region that included present-day France, Belgium, Luxembourg, and southwestern Germany. The name *Merovingian* comes from Merovech, a relative of the first Merovingian ruler, Clovis I.

Clovis I was also the most powerful Merovingian king. He unified the Franks under his rule. By the time he died in 511, he had conquered northern and southwestern Gaul and additional land in what is now western Germany. The kingdom was then divided among four of Clovis' sons, who added southeastern Gaul and other territory to the realm. However, a process of further dividing the kingdom led to numerous civil wars that severely weakened the dynasty. In 751, the last Merovingian king, Childeric III, was replaced by Pepin the Short, the first ruler from the Carolingian dynasty (see **Pepin the Short**). Bernard S. Bachrach

See also **Clovis I; France** (The Carolingian dynasty); **Franks.**

Merrill, James (1926-1995), was an American poet whose favorite theme is memory. Many of Merrill's poems evoke lost times and places, childhood fantasies, moments of intense feeling, dead friends and family, and dwellings that have been left behind. Merrill regarded the French novelist Marcel Proust as one of his

chief inspirations. Like Proust, Merrill shows how past experience is transformed by recollection. His most ambitious effort to chart the transformations of time and loss comes in his long poem *The Changing Light at Sandover* (1982). A major portion of that volume was published earlier as part of *Divine Comedies* (1976), which won the 1977 Pulitzer Prize for poetry.

Merrill's poems are both entertaining and uniquely challenging because of their combination of complex rhyme schemes, sparkling images and metaphors, and ingenious word play. His poems are filled with surprising twists on familiar expressions, designed to make readers pay close attention to the words themselves. Merrill also wrote a prose memoir, *A Different Person* (1993). James Ingram Merrill was born in New York City.

Roger Gilbert

Merrill, Robert (1919-), an American baritone, became one of the world's leading opera stars. He gained recognition for his powerful and resonant voice, which he combined with great warmth and superb technique. Merrill sang all of the major Italian and French baritone operatic roles. He also performed in lighter works, notably in the Broadway musical *Fiddler on the Roof,* and gave many concerts and recitals.

Merrill was born in Brooklyn, N.Y. In 1944, he made his operatic debut in Trenton, N.J., as Amonasro in *Aida.* Merrill made his debut with the Metropolitan Opera in New York City in 1945 in the role of Germont in *La Traviata.* He wrote several books, including an autobiography, *Once More from the Beginning* (1965), and a novel, *The Divas* (1978). Charles H. Webb

Merrill's Marauders, sometimes called Merrill's Raiders, were about 3,000 United States infantrymen who fought under Brigadier General Frank Merrill during World War II (1939-1945). The Marauders were tough jungle fighters who won fame in the China-Burma-India theater. They went to India in October 1943, after President Franklin D. Roosevelt called for volunteers to take part in a "dangerous and hazardous" mission. In March 1944, after a 100-mile (160-kilometer) march, Merrill's Marauders surprised the enemy by blocking the only Japanese supply line in the Hukawng Valley. Charles B. MacDonald

Merrimack. See Monitor and Merrimack.

Merrimack River flows through southern New Hampshire and northeastern Massachusetts. The river is formed where the Winnepesaukee and Pemigewasset streams meet at Franklin, N.H. It empties into the Atlantic Ocean at Newburyport, Mass. Textile mills built along the river in the 1800's contributed heavily to the early growth of the cities of Manchester and Nashua, N.H.; and Lawrence and Lowell, Mass. *Merrimack* is an Indian name meaning *swift water.* For the location of the Merrimack River, see New Hampshire (physical map).

Robert L. A. Adams

Merry-go-round is a popular children's ride at amusement parks, carnivals, and theme parks. The ride is also called a *carrousel* (also spelled *carousel*). A merry-go-round basically consists of brightly painted horses and other animals mounted on a circular platform. Benches that resemble chariots may also be mounted on the platform. Riders sit on the animals and benches. A motor causes the platform to revolve. Some animals are attached to poles that move up and down as the ride moves. On most merry-go-rounds, a mechanical organ plays music while the ride is in motion.

The merry-go-round is the oldest amusement ride still in use. The term *merry-go-round* first appeared as early as 1729 in a poem in an English newspaper. The first known American merry-go-round was operated in Salem, Mass., in 1799. Don B. Wilmeth

Mersey, *MUR zee,* **River,** is an important trade waterway in northwest England. The river rises in the Pennine Hills, flows southwest past Runcorn, and enters the Irish Sea near Liverpool. The Mersey is about 70 miles (110 kilometers) long.

A system of docks and basins extends along both banks of the *estuary* (mouth) of the Mersey at Liverpool and Birkenhead. A railway tunnel under the river connects the two manufacturing centers. An underwater tunnel for highway traffic was completed in 1934. The Manchester Ship Canal connects Salford and Manchester with the river. John W. Webb

Merton, Robert King (1910-), is an American sociologist. He became known for combining social theory and *quantitative* (statistical) research.

In his book *Science, Technology and Society in Seventeenth Century England* (1938), Merton discussed cultural, economic, and social forces that contributed to the development of modern science. He concluded that many Protestant reformers, including the English Puritans, indirectly helped bring modern science into being by encouraging people to study nature.

In his work *Social Theory and Social Structure* (1949), Merton explored why individuals behave in ways that their society considers abnormal. He explained five types of behavior, ranging from *conformity* to *rebellion.* According to Merton, a person who conforms accepts society's goals and its ways of achieving them. A person who rebels tries to change society with new goals and new ways of reaching them.

Merton is regarded as the founder of a field known as the *sociology of science.* This field focuses on the ways social groups, social organizations, and the values of society influence the development of science.

Merton was born in Philadelphia. He graduated from Temple University in 1931 and earned a Ph.D. degree from Harvard University in 1936. He joined the faculty of Columbia University in 1941. Neil J. Smelser

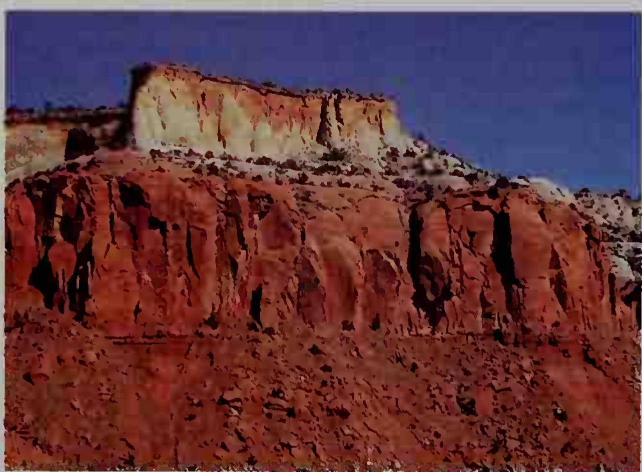
Merton, Thomas (1915-1968), a Roman Catholic monk, was the most popular spiritual writer of his time. Merton won fame for his autobiography, *The Seven Storey Mountain* (1948). The book describes Merton's troubled youth and the experiences that led him to become a Catholic in 1938. The book also deals with his entry in 1941 into the Order of Cistercians of the Strict Observance at Our Lady of Gethsemani Monastery, located near Bardstown, Ky. The members of this order, called Trappists, lead strict and studious religious lives. In 1949, Merton was ordained a Catholic priest. In 1965, he retired to a hermitage.

Merton was born in Prades, France, of an American mother and New Zealand father. He grew up in France and England. Merton wrote over 40 books, many of which record his struggle for greater personal integrity. He also wrote widely on Eastern religions. Merton's better-known publications include *The Sign of Jonas* (1953), *New Seeds of Contemplation* (1961), *Conjectures of a*

Guilty Bystander (1966), and *Faith and Violence* (1968). Merton died by accidental electrocution in Bangkok, Thailand. Richard J. Hauser

Merv is an oasis in central Asia. It covers about 2,000 square miles (5,200 square kilometers) in the vast plateau desert in the southeastern part of Turkmenistan (see **Turkmenistan** [map]).

The Merv has been a center of life and industry for hundreds of years, though it lies in the midst of a great wasteland. The ancient Persians called the Merv "the cradle of the human race." Farming is the chief occupation in the oasis. Some cotton and wool are produced. The ancient town of Merv is in ruins. The modern city, Mary, stands about 20 miles (30 kilometers) west of the old site. It was founded by Russians in 1881. Zvi Gitelman



Merwin, W. S. (1927-), is an American poet and translator. He won the 1971 Pulitzer Prize in poetry for his collection *The Carriers of Ladders* (1970).

Merwin's poems are intense and impersonal. They deal with isolation, violence, and death as well as with moral values and the nature of reality. Merwin explores the strangeness of personal experience in "For the Anniversary of My Death." He wrote about nature and animals in two early collections, *The Dancing Bears* (1954) and *Green with Beasts* (1956). His best-known poems are collected in *The Lice* (1967). Later collections include *Writings to an Unfinished Accompaniment* (1973), *Opening the Hand* (1983), *Travels* (1993), *The Vixen* (1996), and *The River Sound* (1999). Merwin also wrote *The Folding Cliffs* (1998), a historical novel in verse about Hawaii.

Merwin has won praise for his translations of Spanish and French literature. His most important translations include *The Poem of the Cid* (1959), *The Song of Roland* (1963), and *Selected Translations, 1968-1978* (1979).

Merwin's prose works are collected in *The Miner's Pale Children* (1970), *Houses and Travellers* (1977), *Unframed Originals* (1982), and *Regions of Memory* (1986). William Stanley Merwin was born in New York City.
Steven Gould Axelrod

Mesa, *MAY suh,* is an isolated hill or mountain that has a flat, tablelike top and steep sides. *Mesa* is a Spanish word meaning *table.* Mesas are found in dry climates. In the United States, they are common in Arizona, Colorado, New Mexico, and Utah.

Dick Skrondahl

A mesa is an isolated flat-topped hill or mountain with steep sides. The rugged bluffs pictured here are part of the colorful high mesa country of northern New Mexico.

Mesas range in size from a few acres or hectares to hundreds of square miles or kilometers. Mesas were once part of larger plateaus or upland areas that were worn away by erosion over a long period of time. The top of a mesa consists of lava, sandstone, or other types of rock that resist erosion. Beneath it lie layers of less resistant rocks, such as siltstone and shale. The lower slopes of a mesa are covered with large blocks of resistant rock, which broke off from the edges of the mesa when the underlying rock eroded. Lay James Gibson

See also **Butte.**

Mesa, *MAY suh,* Arizona (pop. 396,375), is one of the largest cities in the state. It lies near the Salt River, about 13 miles east of Phoenix (see **Arizona** [political map]). Mesa is part of the Phoenix-Mesa metropolitan area, which has a population of about 3 $\frac{1}{4}$ million.

Mesa is a fast-growing community with a wide variety of businesses. The city serves as the retail and service center for eastern Maricopa County. Several medical centers and large shopping malls are located in Mesa. Major businesses produce electronics, helicopters, heavy machinery, and propulsion equipment. Automotive testing and food processing are also important industries.

The city is the home of Mesa Community College and the Arizona Temple of the Church of Jesus Christ of Latter-day Saints. Mesa's chief tourist attractions include the Arizona Temple Visitors' Center and the Mesa Southwest Museum.

Mesa was founded by Mormons in 1878. The original settlement occupied about 1 square mile (2.6 square kilometers) of elevated ground, overlooking the Salt River Valley. *Mesa* is a Spanish word meaning *table.* Mesa began *annexing* (adding) some of the surrounding area in the 1930's. The city has a mayor-council form of government. Lay James Gibson

Mesa Verde National Park, *MAY suh vurd* or *MAY suh VUR dee.* Hundreds of years ago, Indians known as the Anasazi built high cliff dwellings of stone along the canyon walls of a huge plateau in southwestern Colorado. Some of the cliff dwellings are still standing. In 1906, the United States Congress set aside this region as a national park. The park was named Mesa Verde (Spanish for *green table)* because it is covered with forests of juniper and piñon pines. For area, see **National Park System** (table: National parks).

The Anasazi built their homes in alcoves along overhanging walls of these canyons partly for protection against other tribes. Cliff Palace, the largest cliff house, contains more than 200 living rooms. About 250 to 300 people lived in Cliff Palace at one time. The structure is built much like a modern apartment building. It has sections that are two, three, and four stories high. Cliff Palace also has many underground rooms, known as *kivas,* where the Anasazi held social and religious ceremonies. Spruce Tree House, another large ruin in the park, has about 115 living rooms.

Scientists think most of these homes were built in the 1200's. By about 1300, the Anasazi had migrated to the south and east.

Critically reviewed by the National Park Service

See also **Anasazi** (picture); **Colorado** (picture).

Mesabi Range, *muh SAH bih,* is a chain of hills in northeastern Minnesota. The range was once one of

the great iron ore mining regions of the world. *Mesabi* is an Indian word for *hidden giant.* Most of the range lies in St. Louis County, which is bordered on the southeast by Lake Superior. The range itself is from 60 to 75 miles (97 to 121 kilometers) northwest of the lake.

The Mesabi Range was first leased for mining in 1890 by Leonidas Merritt, three of his brothers, and three of his nephews. By 1896, 20 mines were producing nearly 3 million tons (2.7 million metric tons) of ore a year. The ore was so near the surface that *open-pit mining* was used. Iron ore mining at Mesabi declined sharply during the 1900's, but some low grade ore is still mined there. Thomas J. Baerwald

Mescaline, *MEHS kuh leen,* is a powerful drug that distorts what a person sees and hears and intensifies emotions. Mescaline is obtained from the top, or "button," of the peyote cactus, which grows in parts of Mexico and of the southwestern United States. The Native American Church, which has members from various Indian tribes, uses peyote as a sacrament in religious ceremonies. In the United States, federal law prohibits the possession or use of mescaline except by this church.

The effects of a 350-microgram capsule of mescaline last about 12 hours and resemble those of LSD (see **LSD**). Users may see beautiful color patterns or frightening visions of themselves and others as monsters. A mescaline experience may result in new insights, or it may cause extreme anxiety. A user's personality, the setting, and the dose all affect the experience.

The use of mescaline does not generally produce physical or psychological dependence. But regular users may become unproductive and disinterested in life. In most cases, these reactions end after a person stops taking the drug. Donald J. Wolk

Meshed, *meh SHEHD* (pop. 1,887,405), is one of Iran's largest cities and a leading religious center. It lies on a fertile plain in northeastern Iran. For location, see **Iran** (map). People travel to Meshed each year to visit the gold-domed tomb of Imam Ali Reza, a Muslim leader. Meshed manufactures rugs, shawls, silk goods, porcelain, and jewelry. It also is a trading center for timber, cotton textiles, and animal hides. Meshed was founded around Imam Ali Reza's tomb and became a flourishing town in the 1300's. See **Asia** (picture: Muslims).

Michel Le Gall

Mesmer, *MEHZ muhr,* **Franz Anton** (1734-1815), an Austrian physician, pioneered in the practice of hypnotism. He developed a theory called "animal magnetism," later named *mesmerism.* Mesmer believed that a mysterious fluid penetrates all bodies. This fluid allows one person to have a powerful, "magnetic" influence over another person.

Mesmer was born at Iznang in Austria. His first name has often been given as Friedrich because of a mistake in an early book about him. Mesmer studied medicine in Vienna. He went to Paris to lecture and practice in 1778. His sessions, or *séances,* in which he supposedly "magnetized" patients, created a sensation. But the medical profession considered him a fraud. Mesmer's theories have been discarded, but hypnotism has been accepted as a subject for scientific study and as a means of treating certain disorders. See **Hypnotism** (History).

Hannah S. Decker

Mesolithic Period. See **Stone Age.**

Meson, *MEHS ahn,* is any of about 150 kinds of unstable subatomic particles. *Meson* comes from a Greek word meaning *middle.* Mesons have this name because the first ones found were heavier than an electron but lighter than a proton. However, physicists have discovered that most mesons are heavier than a proton.

A meson is unstable because of its composition. It consists of one quark and one antiquark. An antiquark is a particle of *antimatter.* An antiparticle has the same *mass* (amount of matter) as its corresponding particle, but carries an opposite charge. When a particle of matter and a particle of its antimatter opposite meet, they annihilate each other. A meson's quark and antiquark can avoid meeting for only a tiny fraction of a second.

Mesons differ in the types of quarks and antiquarks they are made of and in the motions of those particles within the meson. The lightest meson is the *pi meson,* also called a *pion.* It comes in three varieties, with electric charges of +1, −1, and 0. The charged pions are the longest-lived mesons, with an average lifetime of 26 *nanoseconds.* One nanosecond is one billionth of a second. The mass of a pi meson is about one-seventh the mass of a proton. The heaviest mesons observed, the *upsilons,* are more than 10 times as heavy as a proton.

Mesons are produced when stable particles, such as protons, collide at high speeds. The collision converts part of the *kinetic energy* (energy of motion) of the particles into a quark and an antiquark. Such collisions often occur when a *cosmic ray,* a bit of matter from space, strikes a particle in the earth's atmosphere. Mesons are also produced in machines called *particle accelerators.*

Japanese physicist Hideki Yukawa predicted the existence of mesons in 1935. In 1947, British physicist Cecil Frank Powell and his colleagues observed charged pi mesons, confirming Yukawa's prediction. Yukawa received the 1949 Nobel Prize for physics for his prediction. Powell received the 1950 prize, in part for his discoveries concerning mesons. Robert H. March

Mesopotamia, *MEHS uh puh TAY mee uh,* was an ancient region in which the world's earliest civilization developed. Mesopotamia included the area that is now eastern Syria, southeastern Turkey, and most of Iraq. It extended from the Taurus Mountains in the north to the Persian Gulf in the south, and from the Zagros Mountains in the east to the Syrian Desert in the west. But the heart of the region was the land between the Tigris and Euphrates rivers. The name *Mesopotamia* comes from a Greek word meaning *between rivers.*

Northern Mesopotamia was a plateau that had a mild climate. Parts of it received enough rain for crops to grow. In southern Mesopotamia, a plain of fertile soil left by floodwaters of the Tigris and Euphrates rivers provided rich farmland. But the long, hot summers and little rain in this area made irrigation necessary for agriculture.

The oldest known communities in northern Mesopotamia were villages established in the Zagros foothills by about 7000 B.C. Traces of villages in far southern Mesopotamia date from the 5000's B.C. Sometime before 3500 B.C., new settlers arrived in this region. Scholars do not know where these people originally came from, but the area they settled became known as Sumer. About 3500 B.C., the Sumerians began to build the

WORLD BOOK map

Location of Mesopotamia

world's first cities and to develop its first civilization. About the same time, the Sumerians invented the world's first system of writing. This system, using word-pictures, developed into a system of wedge-shaped characters called *cuneiform* (see **Cuneiform**).

During the 2300's B.C., people originally from the west called Akkadians conquered Sumer. The invaders were Semites—that is, people who spoke a language related to Arabic and Hebrew. The Akkadians and other Semites formed empires that ruled Mesopotamia for much of the time between 2300 and 539 B.C. The Semitic groups included the Babylonians, Assyrians, and Amorites.

In 539 B.C., Mesopotamia became part of the Persian Empire. The Macedonian ruler Alexander the Great conquered the Persians in 331 B.C. Later, the Seleucids, Parthians, Romans, Sassanids, Arabs, and Mongols ruled Mesopotamia. In the A.D. 1500's, the Ottoman Empire began to establish control over the region. Mesopotamia remained part of the Ottoman Empire until the British occupied the area during World War I (1914-1918). In 1921, most of Mesopotamia became part of the newly created nation of Iraq. Mesosphere, *MEHS uh sfeer,* is a layer of the earth's atmosphere. It lies above the *stratosphere* and below the *thermosphere.* The mesosphere begins at an altitude of about 30 miles (48 kilometers) and extends to about 50 miles (80 kilometers).

The temperature of the air in the mesosphere generally decreases as the altitude increases. At the base of the mesosphere, the temperature averages 28 °F (−2 °C). The lowest temperature in the earth's atmosphere occurs at the top of the mesosphere, called the *mesopause.* In the mesopause over the North and South poles, the air temperature may drop as low as −171 °F (−113 °C). The coldest mesopause temperatures at a pole occur when it is summer there.

Scientists believe that the air in the mesosphere may mix, as it does in the *troposphere,* the lowest layer of the atmosphere. The temperature in both layers decreases with increasing altitude. One indication of variable air motion in the mesosphere comes from watching the zigzag trails of meteors passing through it. Thin clouds have also been sighted in the polar regions of the mesosphere during the summer.

Mesquite, *mehs KEET,* is the name of a group of thorny, low shrubs that grow in dry climates. The most common species, the *honey mesquite,* is found in the southwestern United States, Mexico, and the West Indies. It also grows in the Hawaiian Islands, where it was planted by missionaries.

Grant Heilman

The mesquite tree thrives in dry climates. It needs little water, and its long roots burrow deeply to obtain moisture.

A mesquite needs little water and will grow in deserts too hot and dry for many plants. As parts of the shrub die and decay, they release nitrogen compounds into the soil. As a result, the sandy soil around mesquite often contains enough nitrogen to allow a variety of plants to grow.

In the mid-1900's, mesquite began spreading through rangelands in southwestern North America, displacing large areas of grasses. Ranchers often try to eliminate the shrub because grasses provide better food for cattle and other domestic animals.

When a mesquite has plenty of water, it grows into a large tree. It may become 50 to 60 feet (15 to 18 meters) high with a trunk 3 feet (90 centimeters) across. People use the wood of mesquite for fuel, to make fence posts, and to build dwellings. The seeds or beans serve as food for cattle and horses and were once an important food for the Indians of the Southwest. Two kinds of gum

taken from mesquite are used to make candies and Mexican dyes. Kimball T. Harper

Scientific classification. Mesquites belong to the pea family, Leguminosae or Fabaceae. The scientific name for the honey mesquite is *Prosopis glandulosa.*

Messenia, *muh SEE nee uh,* is a *department* (political division) of Greece. It was also an important region in ancient times. Messenia is located in the *Peloponnesus* (Greece's southern peninsula). It has an area of 1,155 square miles (2,991 square kilometers) and a population of about 160,000. Kalamai is the capital of the department. Messenia's farmland is the richest in Greece.

During the Late Bronze Age in Greece (1550-1100 B.C.), eastern Messenia was controlled by King Menelaus of Sparta, and western Messenia by King Nestor of Pylos (now Pilos). According to legend, both Nestor and Menelaus were among the Greek heroes who fought in the Trojan War. In the 1100's B.C., Dorian invaders from the north overran Messenia. Nestor's palace at Pylos was uncovered in 1939 by American archaeologist Carl Blegen. It is considered one of the great monuments of Bronze Age Greece.

WORLD BOOK map

Messenia lies in southwestern Greece.

In the late 700's B.C., Sparta conquered Messenia and enslaved the people. Messenians revolted unsuccessfully twice, and they stayed under Spartan rule. But in 371 B.C., Thebes defeated Sparta in the Battle of Leuctra and freed the Messenians. The Theban leader Epaminondas helped the Messenians build a new capital and fortress at Messene (now Messini). The walls of that fortress still stand. Messenia remained independent under the protection of Macedonia and the Achaean League until the Romans conquered all of Greece in 146 B.C.

During the Middle Ages (A.D. 400's to the 1500's), Slavs, Franks, Venetians, and Turks occupied Messenia. Frankish and Turkish castles still stand at Kalamai, Koroni, Methoni, and Pilos. Norman A. Doenges

Messerschmitt. See **Airplane** (During World War II).

Messiaen, *mehs YAHN,* **Olivier,** *aw lee VYAY* (1908-1992), was a French composer. His wide-ranging style uses elements of bird calls, church vocal music called *plainsong,* and Greek and Hindu rhythms. His 10-movement symphony, *Turangalila* (1949), features some of these techniques. As a German prisoner of war during World War II, Messiaen composed *Quartet for the End of Time* (1941), his most famous work. He also composed *Twenty Glances at the Infant Jesus* (1944) for piano, *Oiseaux Exotiques (Exotic Birds,* 1955) for piano and orchestra, and the opera *St. Francis* (1983).

Olivier Eugène Prosper Charles Messiaen was born in Avignon, France. In 1931, he became an organist at the Church of the Holy Trinity in Paris. He became a professor of harmony at the Paris Conservatory in 1942. Messiaen taught and greatly influenced many modern composers, including Pierre Boulez of France and Karlheinz Stockhausen of Germany. The most notable of his extensive writings on music is *The Technique of My Musical Language* (1956). Stephen Jaffe

Messiah, *muh SY uh,* is a person who is thought of as a savior or liberator by his or her followers. The term *messiah* comes from a Hebrew word meaning *anointed one.*

The concept of a Messiah is central to Judaism and Christianity. The term *messiah* originally was applied to ancient Hebrew priests and kings who had been anointed with holy oil. During Biblical times, the Jews looked for a Messiah to deliver them from oppression. They also regarded certain prophets as Messiahs. The term came to refer specifically to a descendant of the great Israelite leader King David. This Messiah would bring an age of justice, peace, and prosperity to Israel. However, Jews vary in their expectations about the nature and mission of the Messiah. Some believe in a personal Messiah who will save those who have been faithful. Others think that an era called the *Messianic Age* will come, when peace and freedom will reign.

The notion of an *eschatological Messiah* developed among some Jewish sects. Such a Messiah would come to announce the end of the world. The Book of Daniel refers to an eschatological Messiah called "Son of Man," who will rule "an everlasting kingdom."

Christians believe Jesus is the promised Messiah. They gave Him the title *Christ,* the Greek word for Messiah. Many Christians also believe the Messiah will come again at the end of the world.

Throughout history, especially during periods of social or political unrest, people have claimed to be Messiahs. Some have temporarily gained large followings. Such people are known as *false Messiahs.* Jill Raitt

Messier, *meh SYAY,* **Charles,** *sharl* (1730-1817), was a French astronomer. He prepared the first catalog of *nonstellar* objects visible from the Northern Hemisphere. Such objects include galaxies, *nebulae* (clouds of dust and gas), and star clusters. Messier began the catalog in the late 1750's and completed it in 1784. His listing, called the *Catalogue of Nebulae and of Star Clusters,* contains 103 nonstellar objects. Messier discovered most of these objects himself. Astronomers still specify the objects in his catalog by their catalog numbers, placing an *M* for *Messier* before the number.

Messier did not originally intend to produce a catalog of nonstellar objects. He specialized in tracking comets and, while searching for them, saw hazy objects that did not change position. Messier concluded that these stellar objects were not comets. He recorded their position in the sky so that other astronomers would not confuse them with comets. Messier also discovered 21 comets.

Messier was born in Badonviller, France, near St.-Dié.

He became chief astronomer of the Marine Observatory in Paris in 1759. Frank D. Drake

Messina, *muh SEE nuh* (pop. 231,693), is one of the largest cities in Sicily, an Italian island in the Mediterranean Sea. Messina lies on the northeastern coast of the island, on the Strait of Messina (see **Italy** [political map]). The city serves as a gateway to Sicily. Every day, thousands of people travel by ferry across the less than 2 miles (3.2 kilometers) of water separating Messina and the Italian mainland. Messina, a market center, exports fruit, wine, and other products.

Historians believe that the Greeks founded Messina during the 700's B.C. By 500 B.C., the city had become a well-known Greek colony. Since ancient times, Messina has been fought over by many nations. Earthquakes almost destroyed the city in 1783 and 1908. Messina suffered heavy damage from Allied air raids in 1943, during World War II. David I. Kertzer

Mestizo, *mehs TEE zoh,* is a Spanish word that comes from the Latin *mixtus,* meaning *mixed.* The word refers to a person with mixed ancestry. A mestizo may be someone of mixed white and black or Malay ancestry. More commonly, the term is applied to a person of mixed white and American Indian parentage, especially in Latin America. Douglas H. Ubelaker

See also **Latin America** (People; picture).

Meštrović, *MEHSH truh vihch,* **Ivan** (1883-1962), was an internationally known Croatian sculptor. He worked chiefly in marble, wood, and bronze. Much of his sculpture was strongly influenced by Greek classical styles. Religious and patriotic themes dominate Meštrović's art. Meštrović's major works include the marble sculptures *Maiden of Kosovo* (1907) and *Pietà* (1942-1946).

Meštrović was born in Vrpolje, Dalmatia (now part of Croatia). He learned carving from a master mason in Split. During World War I (1914-1918), he was a leader in the movement to create the nation of Yugoslavia. Meštrović worked and taught mainly in Yugoslavia until the mid-1940's, when he moved to the United States.

Joseph F. Lamb

Metabolism, *muh TAB uh lihz uhm,* is the sum of the chemical processes by which cells produce the materials and energy necessary for life. Metabolism has two phases: (1) *anabolism,* or *constructive metabolism,* during which cells combine molecules to assemble new organic materials, and (2) *catabolism,* or *destructive metabolism,* during which cells break down molecules to obtain energy and release heat. All organisms conduct both phases constantly. This article specifically discusses human metabolism, but the processes are similar in other higher animals.

Control of metabolism. Hormones control both the rate and direction of metabolism. For example, thyroxine, a hormone secreted by the thyroid gland, plays a key role in determining the rate of metabolism. Hormones secreted by special cells in the pancreas determine whether most of the body's metabolic activity will be anabolic or catabolic. The body conducts more anabolic than catabolic activities after a meal. Eating increases the level of glucose in the blood. The pancreas responds to this high level of glucose by releasing the hormone insulin. Insulin serves as a trigger for cells to begin anabolic activities. When the level of glucose is low—for example, when a person is fasting—the pancreas releases the hormone glucagon. Glucagon signals the cells to conduct more catabolic processes.

The rate of metabolism when a person is at rest is called the *basal metabolic rate* (BMR). The BMR is a measure of the heat produced by metabolism. This rate varies among people according to sex, age, and body size. Dietitians measure the BMR to determine a person's caloric needs. At one time, physicians used the BMR to detect an overactive or underactive thyroid gland. Since the 1970's, doctors generally have diagnosed such disorders with tests that measure the blood levels of thyroid hormones.

Raw materials of metabolism. Most series of metabolic reactions involve molecules of glucose, fatty acids, or amino acids. The diet is the basic source of these molecules. During digestion, enzymes split dietary proteins into amino acids, dietary fats into fatty acids and glycerol, and dietary *carbohydrates* (starches and sugars) into simple sugars, particularly glucose. These compounds are then absorbed and transported by the blood to the cells.

Anabolism produces complex compounds by combining simpler molecules. During anabolism, cells combine amino acids to form *structural proteins* and *functional proteins.* The body repairs and replaces tissues with structural proteins. Functional proteins perform specific jobs. Functional proteins include enzymes, which speed up chemical reactions; antibodies, which help fight disease; and many hormones, which regulate various body processes.

Cells convert glucose and fatty acids to energy storage compounds during anabolism. Cells in the liver and the muscles combine molecules of glucose to form a storage compound called *glycogen.* Cells in the body's *adipose* (fatty) tissues combine fatty acids with glycerol to form body fat. By a complex series of reactions, excess glucose and amino acids also can be converted into body fat.

Catabolism is the breaking down of glucose, fatty acids, and amino acids to obtain energy and produce heat. Compounds involved in catabolism come either from newly digested food, the breakdown of storage glycogen or fat, or the breakdown of body protein.

Glucose catabolism has two steps. The first step, *glycolysis,* works without oxygen. Glycolysis breaks down glucose into pyruvic acid and releases a small amount of energy. If oxygen is present, the pyruvic acid is converted to a compound called *acetyl-coenzyme A* (abbreviated *acetyl-CoA*). The second step of glucose catabolism, the *Krebs cycle,* then takes place. In the Krebs cycle, a series of chemical reactions combines acetyl-CoA with oxygen to produce carbon dioxide and water, and to obtain energy.

The catabolism of fatty acids also has two steps. First, enzymes convert fatty acids to acetyl-CoA. Acetyl-CoA then enters the Krebs cycle. Although amino acids generally serve as building blocks for new proteins, the body may use excess amino acids as an energy source. Before they can be catabolized, amino acids must be chemically altered in the liver or other tissues. They can then enter the Krebs cycle.

About 60 per cent of the energy released during catabolism takes the form of heat. The rest of the energy is

stored in the chemical bonds that link atoms in a compound called *adenosine triphosphate,* or *ATP.* When the body needs this energy, enzymes break the bonds and release it. Patricia B. Swan

Metal forms a large part of the earth on which we live. Nearly 80 percent of the known elements are metals. Metals are important in all aspects of construction and manufacturing. Industries use metals and combinations of metals called *alloys* to build cars and a wide variety of machinery. Compounds that contain metals are used in drugs, batteries, and many other products.

What metal is. Metals have certain properties that distinguish them from other elements. Metals reflect light and have a shiny appearance. They also are good conductors of electricity and heat. Most metals are *malleable*—that is, they can be hammered into thin sheets. Most metals are also *ductile,* which means that they can be drawn out into wires.

In a chemical reaction with a nonmetal, a metal atom gives up one or more electrons to the nonmetal. For example, the metal sodium (Na) reacts with chlorine (Cl) to form the compound sodium chloride (NaCl). In this chemical reaction, each sodium atom gives up one electron, which has a negative charge, to form a positive sodium ion (Na). The chlorine takes on this electron to become a chloride ion (Cl). The oppositely charged ions bond to form NaCl—common table salt.

The properties of a pure metal are different from the properties of a compound containing the metal. For example, in the metallic state, sodium is shiny and highly malleable, and it is extremely reactive with air. But the compound sodium chloride is colorless and brittle, and is stable in air.

In the earth's crust, most of the metallic elements occur in compounds and not in the metallic state. For example, the earth's crust includes about 8 percent aluminum, 5 percent iron, and 4 percent calcium. All these are present in compounds. A few of the rare and least reactive metals may be found in the metallic state in the earth's crust. These metals include copper, gold, mercury, and platinum. Scientists think the earth's core is mainly made up of iron in the metallic state.

Combinations of metals retain the properties of metals. These combinations include bronze, bell metal, gun metal, and type metal. The alloys and metals that do not contain iron are referred to as *nonferrous* alloys and metals.

Metals through the ages. Ancient people knew and used many native metals. Gold was used for ornaments, plates, jewelry, and utensils as early as 3500 B.C. Gold objects showing a high degree of culture have been excavated at the ruins of the ancient city of Ur in Mesopotamia. Silver was used as early as 2400 B.C., and many ancient people considered it to be more valuable than gold, because it was rarer in the native state. Native copper also was used at an early date for making tools and utensils, because it was found near the surface of the ground and could be easily worked and shaped.

Since about 1000 B.C., iron and steel have been the chief metals for construction. Today, supplies of the best iron ore for steelmaking are being exhausted. The same is true for copper, lead, and zinc deposits. The earth's supply of aluminum is almost unlimited.

Magnesium, another light, strong metal, has also become important. It is extracted from sea water and the common rock called *dolomite.* The radioactive metal uranium is used as a fuel in nuclear reactors.

Metal detector is an instrument used to locate hidden or lost metal objects. It gives off signals in the presence of metal. Detectors are widely used by treasure hunters, who search outdoors for old coins, jewelry, and other valuable relics. Police use metal detectors in criminal investigations. Archaeologists and prospectors also use them.

Metal detectors vary in design and shape, but they all operate in basically the same way. A detector transmits radio waves by means of an antenna. A metal object absorbs some of these waves and reflects them back to the instrument. The detector's receiving circuit amplifies the reflected waves into a strong signal that tells the user of the object's presence.

All detectors can locate metals that lie buried underground or are hidden behind brick or stone walls. Many detectors have a feature called a "discriminating circuit," which distinguishes objects made of valuable metal from those of a nonvaluable material. Metal detectors are manufactured in a number of sizes. Most of these

Garrett Electronics

A metal detector is used to find coins, jewelry, and other valuable objects that are buried underground.

instruments can be easily carried by their users.

Charles L. Garrett

Metal fatigue is the gradual weakening of metal after extensive use. Such weakening is caused by the repeated application of tension, pressure, or other forms of stress. Stress cycles often alter the molecular structure of the materials so that they crack. Metal fatigue usually begins at the surface of a metal piece where small defects, or even minute tool marks, serve as a concentration point for stress. The crack spreads through the piece, eventually making it too weak to carry its normal load. Engineers allow for metal fatigue in planning airplanes, bridges, and machinery. Gordon H. Geiger

Metallography, *MEHT uh LAHG ruh fee,* is the study of the internal structure of metals and alloys. The term also may be applied to the study of ceramics and *composites* (combinations of materials that often include metals). Metallographers determine how materials will react under certain conditions, such as extreme heat or cold. Industry depends on metallography in the creation, testing, and improvement of such products as missiles and spacecraft. Metallographers study material samples with X rays and microscopes. Powerful electron microscopes have helped them develop new kinds of materials. I. Melvin Bernstein

Metallurgical engineering. See Metallurgy; Engineering (Materials engineering).

Metallurgy, *MEHT uh LUR jee,* is the science of separating metals from their *ores* (the minerals or rocks in which they are found), preparing them for use, and improving their performance. Metallurgy falls into two major divisions: *extractive,* or *process, metallurgy;* and *physical,* or *alloy, metallurgy.*

Extractive metallurgy

Extractive metallurgy deals with taking metals from their ores and *refining* (purifying) them. It includes a wide variety of specialized commercial processes, such as mineral dressing, roasting, sintering, smelting, leaching, electrolysis, and amalgamation.

Mineral dressing occurs between the mining of the ore and the extraction of metals from it. Mineral dressing removes as much of the waste materials as possible from the ore. This process usually begins by grinding the ore so that the metals in it, along with certain nonmetallic materials, separate from the waste. Then the various waste materials may be floated or washed away. In this *flotation process,* crushed ore is *agitated* (set in motion) in water with bubbles of air or gas. Various chemicals or oils that have been added to the water cause the mineral particles to stick to the bubbles. The minerals are then removed in a froth. The waste materials that remain are called *gangue* (pronounced *gang*). The removal of the gangue reduces the amount of ore that must be handled when the metal is extracted. Because this ore has a higher concentration of metal, it can be more economically refined into the final metal.

Roasting removes sulfur and other impurities from the ore. When the ore is heated in air, the sulfur and certain other impurities combine with the oxygen in the air, and pass off as gases. The remaining solid material contains a *metallic oxide* (combination of metal and oxygen) that must be further purified or reduced to yield the pure metal.

Sintering may occur when the temperature at which ores are roasted becomes very high. In this process, fine particles in contact with one another join to form coarse lumps. The joining is caused by surface tension. It is the same force that causes small water drops to combine into larger drops. Sintering is sometimes accompanied by partial melting of the fine particles, but the particles often remain entirely solid during the process. The coarse lumps produced by sintering are easier to handle and use in later processes.

Smelting. After the ores have been subjected to such preliminary processes as dressing, roasting, or sintering, processors begin the actual work of extracting the metal. The usual method of metal extraction is *smelting* (melting the ore in such a way as to remove impurities). In the case of iron, for example, the ore is placed in a huge, brick-lined furnace called a *blast furnace,* and subjected to high heat. Quantities of coke and limestone also are placed in the furnace. As the heat of the furnace is raised, the coke begins to burn and give off carbon monoxide. This gas takes oxygen from the ore, helping to purify the iron.

Many of the other impurities of the ore melt and combine with the limestone to form a liquid collection of *refuse* (waste materials) which is usually lighter than the iron. This refuse rises to the top of the molten metal, and is taken from the furnace as slag. The slag is drawn off from holes in the side of the furnace at a height above the level of the molten iron. The molten iron is still not completely free of impurities. But almost all the iron has been taken from the ore. The metal must now

be refined further, usually by causing it to react with oxygen in a furnace.

Leaching. Some metals can be effectively separated from their ores by *hydrometallurgy* (leaching). This is a method of dissolving the metal out of the ore with a chemical solvent. The metal may then be recovered from the chemical solution by a process called *precipitation.* For example, gold is usually separated from its ore by treating the ore with a dilute alkaline solution of sodium cyanide. After the gold is dissolved in the sodium cyanide, it is placed in contact with metallic zinc. This causes all the gold to *precipitate* (separate) from the solution and gather on the metallic zinc.

Electrolysis. After the metal has been taken from its ore by leaching, it is sometimes recovered from the leaching solution by electrolysis. For example, copper is leached from some ores with sulfuric acid. Then it is placed in an electrolytic cell. There, electric current flows from a lead *anode* (positive pole) through the solution to a copper *cathode* (negative pole). The copper particles in the solution have a positive charge. These particles then seek their opposites, or the negatively charged copper cathode. Aluminum and magnesium also are recovered by electrolysis.

Electrolysis is also used to purify the metal. Copper is one of the metals that can be refined by electrolysis. The impure metal is used as the anode. When electric current is passed through the solution, the atoms of pure copper on the anode give up electrons and pass into solution as positively charged particles. These particles pass through the solution toward the cathode. There, they acquire the necessary electrons to become neutral copper atoms. Most impurities are left behind, and a plating of purified copper forms on the cathode.

Amalgamation is a method that is sometimes used to recover gold and silver from their ores. A solution carries finely ground particles of ore over plates covered with mercury. The mercury attracts the metal and combines with it. The mercury forms an alloy, called an *amalgam,* with the gold or silver. Then the amalgam is heated. The heat causes the mercury to come to a boil and pass off as a gas, which is recovered and recycled. This process leaves behind a metallic sponge of pure gold or silver.

Physical metallurgy

Physical metallurgy is the branch of metallurgy that adapts metals for their final use and improves their performance. It includes any operation used to process a refined commercial metal into a finished product.

Different metals may be mixed to create a metal with special properties. Metal mixtures are called *alloys.* For example, mixing steel with nickel and chromium produces a strong, chemically resistant material called *stainless steel.* Heat treatments may improve such properties as strength and *ductility* (ability to be shaped). New metallic alloys include nickel base *super alloys,* which are used in jet engines. *Shape memory alloys* change shape in response to changes in temperature.

Metal is formed into its final shape by casting, rolling, forging, welding, pressing, extrusion, drawing, stamping, and other methods. Surface treatment may include heating and *carburizing* (combining with carbon). A coating may also be applied to the metal's surface. For example, in a process known as *galvanizing,* a thin layer of zinc is applied to iron or steel to prevent rust.

New combinations of metallic and nonmetallic materials, called *composites,* are replacing traditional metallic alloys for many uses. Some composites are made of nonmetallic materials only. These include fiberglass and carbon epoxy, which is used in sports equipment and jet fighters. Another new approach involves the production of powders of metals and nonmetals. For example, in a process called *gas atomization,* droplets of molten metal are sprayed with gas to form very fine solid particles. These particles can be combined at high temperatures and under high pressure to form alloys with special properties.

History

Metallurgy is one of the oldest sciences. The people of prehistoric times knew something of physical metallurgy. For example, the ancient Chinese and Egyptians found gold and silver in their pure state as grains and nuggets, and hammered the metal into many different kinds of ornaments and other objects. The American Indians found large amounts of pure copper in the area near Lake Superior and hammered the metal into weapons, implements, and jewelry.

Sometime before written history began, some of the ancient peoples discovered the simplest principles of smelting metals from their ores. Lead was probably the first metal ever to be separated from its ore by smelting, because this ore is very easy to smelt. But as long as 4,000 years ago, the Egyptians knew how to separate iron from its ore—and iron ore is considered one of the hardest to smelt. By the time of the Assyrian civilization, the smelting of iron ore was a highly developed art. The ancient Assyrians even knew how to change iron into steel. In the Middle Ages, when alchemists were studying ways to make gold from other substances, great advances were made in metallurgy. The alchemists laid the foundations of the modern science of metallurgy. See **Metal** (Metals through the ages).

Careers in metallurgy

A growing demand for new alloys and composites and new treatments for pure metals has increased the importance of metallurgy as a career. *Metallurgists,* also called *metallurgical engineers,* can find jobs in industries that extract, adapt, and use metals. The mining industry also employs large numbers of metallurgists. Other openings are available in other industries, in government, and in research.

Metallurgists and other persons interested in materials production have increased their efforts to explain complex metallurgical behavior in terms of the basic laws of physics and chemistry. They also have extended the use of metallurgical research methods and skills to such nonmetallic materials as ceramics, semiconductors, plastics, organic solids, and glass. The name *materials science* has been given to the field that deals with both metals and nonmetals.

People interested in metallurgy or materials science as a career should have an aptitude in science and should take as many high-school science and mathematics courses as possible. Most jobs require a bachelor of science degree in metallurgical or materials engineer-

ing. Most research positions require an advanced degree. I. Melvin Bernstein

Metamorphic rock, *meht uh MAWR fihk,* is one of the three main types of rock in the earth's crust. It forms from the other two main types, *igneous* and *sedimentary.* For example, marble is a metamorphic rock that forms from the sedimentary rock limestone. Schist and slate are metamorphic rocks that come from shale.

Metamorphic rock forms when heat or pressure, or both, cause changes in the "parent" rock. One of the changes is the formation of new minerals, called *recrystallization.* The new mineral grains often are larger than the old ones. Also, platy materials, such as mica, may crystallize in parallel planes. When this happens, the rock breaks easily along these planes. This characteristic of metamorphic rocks is called *rock cleavage.*

Several processes can create metamorphic rock. In *contact metamorphism,* heat produced by nearby *magma* (molten igneous rock) causes recrystallization. In *regional metamorphism,* both heat and pressure change rock. Pressure comes from the burial of the rocks deep in the earth's crust. Movements in the earth's crust may also affect the rock by deforming it. These movements are often associated with the formation of mountains. In a less common process, *dynamic metamorphism,* only deformation due to crustal movements alters rock. In *hydrothermal metamorphism,* hot water provides heat that changes the rock. The water often also reacts with the rock, causing chemical changes. Maria Luisa Crawford

Metamorphism, *MEHT uh MAWR fihz uhm,* is the set of processes by which rocks are changed in form. During metamorphism, the size, shape, and arrangement of the minerals in rocks are modified. As a result, new minerals may form or existing minerals may increase in size.

Metamorphism is caused by heat or pressure or both, and sometimes fluids. Metamorphism does not involve the melting of rock or the addition or subtraction of chemicals. In *contact metamorphism,* rocks change as a result of contact with a hot *igneous* body, such as a lava flow. The change caused by the heat and pressure below the earth's surface is called *regional metamorphism.* Regional metamorphism often occurs over a large area. *Dynamic metamorphism* includes changes that result from high pressure and low temperatures, such as those at the surface of a large fault. John C. Butler

See also **Metamorphic rock; Rock** (Metamorphic rock; table).

Metamorphosis, *MEHT uh MAWR fuh sihs,* is a Greek word that means *transformation.* Biologists use this word to describe the extreme changes in form and appearance that occur in lower animals between the growing phase of life and the mature adult phase.

Such higher animals as cats, dogs, and horses—like human beings—are similar in form and structure to the adult when they are born. They differ chiefly in size from the mature animals. These animals exhibit what is known as *direct development.* When such lower animals as ants, butterflies, and sea urchins emerge from the egg, they appear to be different from their parents. In many of these young animals, major changes in structure and appearance must occur before they become adults.

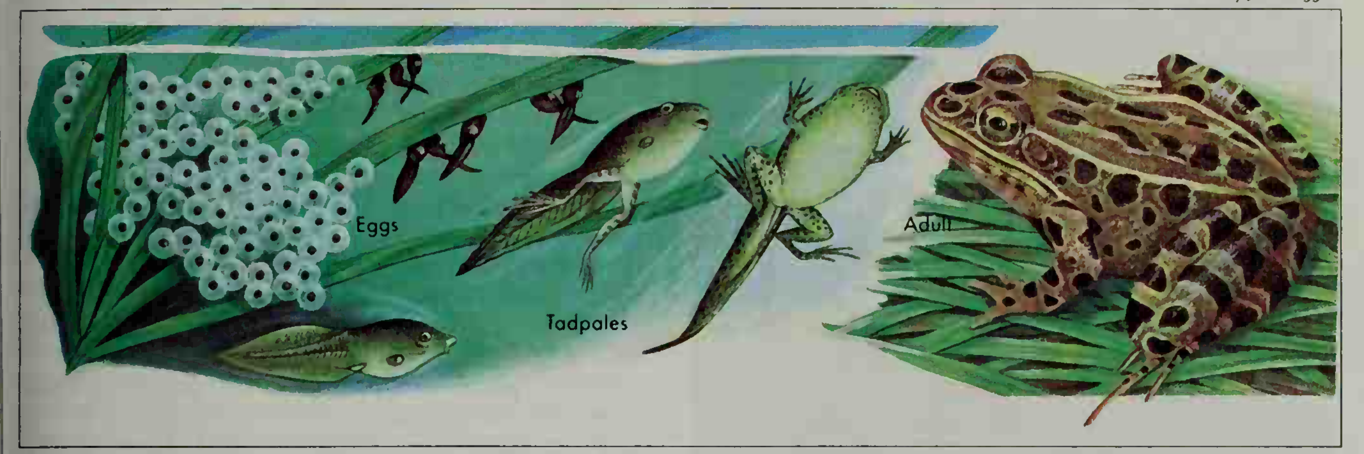
The changes that occur in the life cycle of a butterfly or a moth are among the most striking examples of metamorphosis. Because butterflies and moths pass through four distinct stages, scientists consider them as examples of *complete metamorphosis.* The first stage is the egg in which the embryo forms. Eggs of butterflies and many moths are deposited on plants that will provide food for the next stage, called the *larva.*

The larva of a butterfly or a moth is also known as a *caterpillar.* Caterpillars may be hairy, spiny, or smooth-skinned. They may be a single color or have striking colors or patterns. Caterpillars differ from the adult in having suckerlike *prolegs* on the abdomen and chewing mouthparts. The adult lacks prolegs and has sucking mouthparts. In addition, caterpillars have no wings.

Caterpillars grow rapidly, *molting* (shedding) their outer skins several times. After about a month in the larval stage, a butterfly caterpillar attaches itself to a twig or other support. Then it molts once more to enter the third stage of metamorphosis, the *pupa.* Many moths form a cocoon before entering the pupal stage. Other moths pupate in underground cells or in plant stems.

The pupa. During the pupal stage, the developing butterfly or moth is inactive. The butterfly pupa, also called a *chrysalis,* is protected only by its abdomen.

Complete metamorphosis of a house fly



During the life cycle of a house fly, the egg hatches into a larva, which eats and grows and then forms a pupa. Inside the pupa, the adult develops and emerges from the pupa shell.

WORLD BOOK illustration by Shirley Wheeler, Oxford Illustrators Limited

Metamorphosis of a frog

WORLD BOOK illustration by John F. Eggert

Within the pupal case, larval structures are replaced by those of the adult. Usually there is a another period of inactivity, known as *diapause,* in which even these changes cease. The pupal stage is ideal for passing periods of environmental extremes, such as drought or winter. The pupal stage may last only a few days, or several months, depending on climate and species.

The adult. The adult insect, also called the *imago,* emerges by pushing against its pupal casing, which splits open. The adult crawls onto a twig or other support and pumps blood into its shrunken wings until they are full-size and strong. It then flies away to feed on liquid food, such as flower nectar or tree sap, and carry out its reproductive functions.

Other examples. Beetles, flies, bees, wasps, ants, and many other insects exhibit complete metamorphosis. More primitive insects, including grasshoppers and cockroaches, have only three stages: egg, *nymph* (larva), and adult. This type of metamorphosis, which lacks the pupal stage, is called *incomplete metamorphosis.*

Metamorphosis occurs in most other major animal groups. Among *vertebrates* (animals that have backbones), frogs and toads are the best-known examples. They lay eggs in water, and the eggs hatch into legless tadpoles with tails and gills. A tadpole gradually develops into a four-legged frog, as lungs replace the gills and the tail disappears. Unlike tadpoles, which must live in water, frogs and toads can survive both in and out of water. Charles V. Covell, Jr.

Metaphor, *MEHT uh fuhr* or *MEHT uh fawr,* a figure of speech, is an expression taken from one field of experience and used to say something in another field. For example, when we say, "He's a sly fox," we are using metaphor. That is, we are using the name of an animal to describe a man. A metaphor suggests a comparison without using the word *like* or *as.* The statement "He is *like* a sly fox" or "He is sly *as* a fox" is a simile (see **Simile**).

Everyday speech is rich in metaphors. If we ask someone, "Did you *land* a job today?" the reply may be, "No, not a *bite."* These words from the special language of *fishing* are used to express thoughts about job-hunting. Common words actually develop new senses when they are repeatedly used as metaphors. For instance, we hardly realize that in the phrase "table leg," the word *leg* was originally a metaphor. But when told not to "make pigs of yourselves," we are probably aware of the unpleasant comparison the metaphor suggests.

Metaphors are important in the speech of politicians, scientists, and journalists. In 1946, Sir Winston Churchill used the now-famous phrase "iron curtain" to describe an international problem. Scientists speak of the "wave theory of light." And the phrase "priming the pump" is sometimes used to refer to government spending to stimulate a nation's business and industry. In each case, the metaphor has been an important tool of thought.

Great works of literature are enriched by metaphor. Psalm 23 of the Bible is based on a metaphor. It begins with the words, "The Lord is my shepherd," and suggests the relation of God to humanity by considering the relation of a shepherd to sheep. The plays of Shakespeare contain brilliant metaphors, such as the passage in *As You Like It* beginning, "All the world's a stage."

Mixed metaphors, using two or more unrelated metaphors in the same expression, are often unintentionally amusing. An example: "I smell a rat, but we shall nip it in the bud." Paul B. Diehl

Metaphysical poets, *MEHT uh FIHZ uh kuhl,* is the name given to certain English poets of the 1600's who were influenced by John Donne, the most important member of the group. Donne wrote on both religious and nonreligious subjects. Metaphysical poets who wrote mainly on religious subjects included Richard Crashaw, George Herbert, and Henry Vaughan. Lord Herbert of Cherbury, John Cleveland, Abraham Cowley, and Andrew Marvell wrote mostly on nonreligious topics.

Metaphysical poetry contains irregular, "unpoetic" rhythms and colloquial language. It also sometimes uses far-fetched or outlandish comparisons, either similes or metaphors, called *metaphysical conceits.* The metaphysical conceit often extends a comparison to great length to describe an emotion, idea, or situation.

In the late 1700's, English critic Samuel Johnson first named this group "metaphysical poets" in his *Lives of the Poets* (1779-1781). Johnson criticized their exhibition of learning and especially their use of metaphysical conceits. Despite Johnson's label, however, these poets

were actually no more "metaphysical" in the philosophical sense than other thoughtful writers.

After being condemned by critics like Johnson, the metaphysical poets returned to favor in the early 1900's. The essays of T. S. Eliot helped stimulate this revival. Modern poets influenced by the group include Eliot, Wallace Stevens, Hart Crane, Elinor Wylie, and Richard Eberhart. Gary A. Stringer

Metaphysics, *MEHT uh FIHZ ihks,* is the branch of philosophy concerned with the basic nature of reality. Its aim is to give a systematic account of the world and the principles that govern it. In contrast to the natural sciences, which study specific features of the world, metaphysics is a more general investigation into the fundamental features of what exists. The metaphysician relies on forms of analysis that depend on pure reason rather than the experimental methods of the natural scientist. Metaphysical speculation has always focused on certain key concepts such as space and time, causality, identity and change, possibility and necessity, universals and particulars, and mind and body.

Space and time. When philosophers want to understand the nature of the universe, they often begin by examining the nature of space and time. Such questions as "Can there be time without change?" and "Is space something distinct from the objects in the universe?" belong to the realm of metaphysics. Some metaphysicians have argued that space and time are *absolute*—that is, independent of any change in the arrangement of the contents of the universe. But according to the relativistic account, both space and time can be reduced to the relationships between things in the universe.

Causality. Theories of causality attempt to answer questions about how or why events happen. The concept of causality is closely related to problems of *determinism* and free will. Determinism states that strict causal laws govern all events, even human actions. *Nondeterministic* metaphysical theories claim that events are not controlled by external causes. These theories state that people freely choose their own actions, and in any situation could choose otherwise than they actually do.

Identity and change. Studying the relationship between identity and change helps philosophers understand how things can persist through time even though they seem to change. Most people will agree that objects can change without becoming different things. For example, a coat of paint will not transform a house into a different house. However, it is unclear to what extent changes can take place without destroying the original object. Thus, if we gradually replace all the parts of a house, it seems that we will have slowly destroyed the old house and built a new one in its place. Some metaphysical theories distinguish an object's *form,* or organization, from the matter out of which it is made. They argue that the form persists through time and guarantees the identity of the object through changes.

Possibility and necessity. When philosophers want to know how people make judgments of truth, they often examine the concepts of possibility and necessity. These questions are related to issues of *necessary truths* and *contingent truths.* That there are 9 planets in our solar system is a contingent truth, because there could be 10 planets or even no planets. On the other hand, the fact that $2 + 2 = 4$ is a necessary truth, because it could not be otherwise. Once philosophers have distinguished between possibility and necessity, they can consider whether there are essential properties of objects. If it is a necessary truth that a thing have a certain property, philosophers call that property an *essential* property. Thus, warm-bloodedness is presumably an essential property of dogs, and brownness is an *accidental* (nonessential) property of some dogs.

Universals and particulars. Thinking about the nature of objects and their properties often leads philosophers to discussions of universals and particulars. A universal is something that many separate things have in common. A particular is an object with many properties. For example, the property of redness is common to many individuals. Some metaphysicians believe there is therefore a universal redness. *Realism* about universals is the doctrine that universals can exist separately from particulars and that there is a universal redness common to all red things. Thus, in a realistic theory, universal redness is something more than the totality of all red things. In contrast, *nominalistic* theories claim that there is no universal redness and that *red* is simply a word that people apply to all red things in the world.

Mind and body. Many metaphysical problems arise from the observation that mind and body seem to interact, even though they appear to have nothing in common. These problems can be phrased in such questions as "Is the mind a physical thing?" and "Are people's minds identical with their brains?" *Dualism* contends that mind and matter are two fundamentally distinct kinds of things. A basic problem for dualism is to explain how a physical process can have a nonphysical effect, or how mental events can result in changes in the physical world. *Monism* denies that mind and matter are two different things. Monism can be either *materialistic,* asserting that only matter exists, or *idealistic,* claiming that mind is basic to everything.

Opinions about metaphysics. The apparent failure to reach widespread agreement on metaphysical issues has prompted some philosophers to insist that these questions are beyond the power of human beings to answer. In the early 1900's, philosophers who called themselves *logical positivists* argued that metaphysical questions were meaningless because no amount of evidence could possibly decide them one way or another.

The positivists' critique of metaphysics was widely accepted in the 1920's and 1930's, but most philosophers today are less inclined to dismiss metaphysical theories. There are no easy answers to metaphysical questions. But philosophers now believe that they can judge these theories by how well they satisfy people's basic intuitions, and combine with accepted scientific theories to provide a unified view of the world. Douglas M. Jesseph

Metcalfe, Charles Theophilus (1785-1846), Baron Metcalfe, a British statesman, served as governor-general of Canada from 1843 to 1845. He clashed with members of the Canadian Cabinet by making official appointments without first seeking their advice. This conflict continued a bitter struggle between the Reform and Conservative parties over *responsible government* (self-

government). The election of 1844 showed that a small majority favored Metcalfe's policy. But poor health soon forced him to resign.

Metcalfe was born on Jan. 30, 1785, in Calcutta (now Kolkata), India. He attended Eton College in England. He served in the British civil service in India from 1801 to 1836, and as governor of Jamaica from 1839 to 1842.

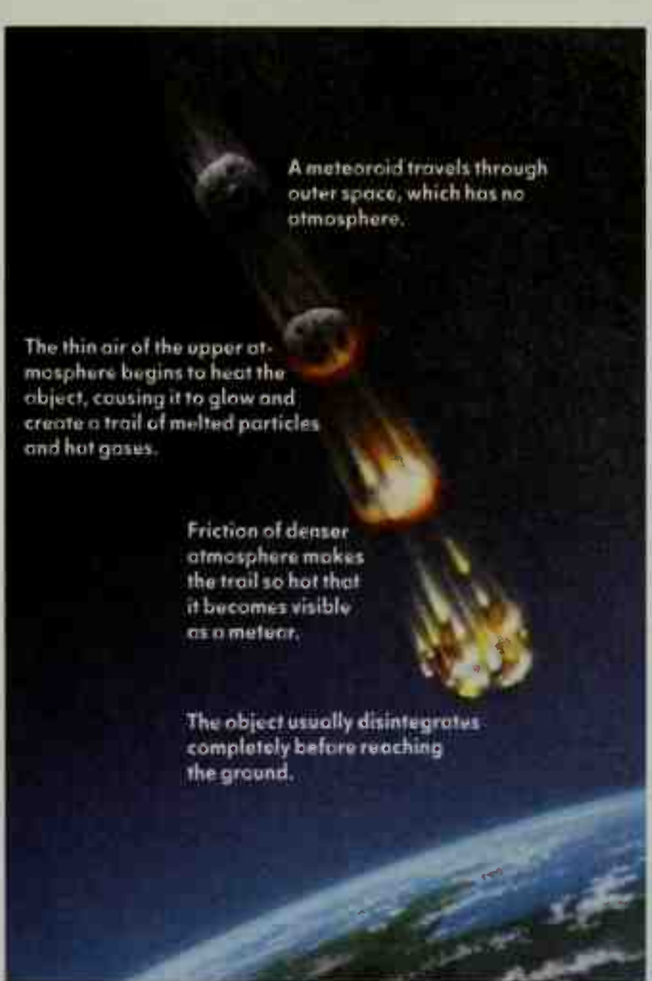
David Jay Bercuson

Metchnikoff, *mehch nee KAWF,* **Élie,** *ay LEE* (1845-1916), was a Russian biologist. He shared the 1908 Nobel Prize for medicine for his work in *immunology* (the study of immunity). In particular, he discovered the function of *phagocytes.* In the human immune system, phagocytes are white blood cells that attack disease germs. Metchnikoff determined that inflammation at a wound is caused when phagocytes surround germs. Doctors at first opposed his ideas on phagocytes. But his discovery was generally accepted before his death.

Metchnikoff's writings include *Immunity in Infectious Diseases* (1901) and *Lectures on the Comparative Pathology of Inflammation* (1892). He later studied aging. In *The Prolongation of Life* (1905), he suggests that eating cultures of sour milk bacteria, commonly available in yogurt, would slow the aging process.

Metchnikoff was born on May 15, 1845, in Ivanovka, near Kharkov. He studied in Russia and Germany and taught zoology at Odessa University. He joined the staff of the Pasteur Institute in Paris in 1892 and became its subdirector in 1895. Dale C. Smith

Meteor is a bright streak of light that appears briefly in the sky. Observers often call meteors *shooting stars* or *falling stars* because they look like stars falling from the sky. People sometimes call the brightest meteors *fireballs.* A meteor appears when a particle or chunk of metallic or stony matter called a *meteoroid* enters the earth's atmosphere from outer space. Air friction heats the meteoroid so that it glows and creates a shining trail of gases and melted meteoroid particles. The gases include vaporized meteoroid material and atmospheric gases that heat up when the meteoroid passes through the atmosphere. Most meteors glow for about a second.



Most meteoroids disintegrate before reaching the earth. But some leave a trail that lasts several minutes. Meteoroids that reach the earth are called *meteorites.*

Millions of meteors occur in the earth's atmosphere

Meteor Crater Enterprises

The Meteor Crater in Arizona lies between the towns of Flagstaff and Winslow. Scientists believe that a meteorite struck the earth about 50,000 years ago and dug a hole about 4,180 feet (1,275 meters) across and 570 feet (175 meters) deep.

WORLD BOOK illustration by Rob Wood

A meteor appears in the sky whenever an object called a *meteoroid* hurtles into the earth's atmosphere from space.

every day. Most meteoroids that cause meteors are about the size of a pebble. They become visible between about 40 and 75 miles (65 and 120 kilometers) above the earth. They disintegrate at altitudes of 30 to 60 miles (50 to 95 kilometers).

Meteoroids travel around the sun in a variety of orbits and at various velocities. The fastest ones move at about 26 miles per second (42 kilometers per second). The earth travels at about 18 miles per second (29 kilometers per second). Thus, when meteoroids meet the earth's atmosphere head-on, the combined speed may reach about 44 miles per second (71 kilometers per second).

Meteor showers. The earth meets a number of *streams* (trails) or *swarms* (clusters) of tiny meteoroids at certain times every year. At such times, the sky seems filled with a shower of sparks. Streams and swarms are believed to be fragments of comets.

The most brilliant meteor shower known took place on Nov. 12-13, 1833. It was one of the *Leonid showers,* which occur every November and seem to come from the direction of the constellation Leo.

Meteorites. There are three kinds of meteorites, *stony, iron,* and *stony-iron.* Stony meteorites consist of minerals rich in silicon and oxygen, with smaller amounts of iron, magnesium, and other elements. One group of stony meteorites, called *chondrites,* are pieces of the same material from which the planets formed. Another group of stony meteorites, the *achondrites,* were

P. Hollembeak, American Museum of Natural History

The Willamette meteorite is the largest meteorite ever found in the United States. It measures 118 inches (287 centimeters) long and weighs about 15 $\frac{1}{2}$ tons (14 metric tons). Rust and atmospheric friction caused pits in one side. It was named after Oregon's Willamette Valley, where it was found in 1902.

Important meteor showers

Shower	Date
Quadrantid	January 3
Lyrid	April 21
Eta Aquarid	May 4
Delta Aquarid	July 29
Perseid	August 12
Orionid	October 22
Taurid, North	November 1
Taurid, South	November 16
Leonid	November 17
Geminid	December 12

once part of a parent body, such as an asteroid, that was large enough to have melted and separated into an iron-rich core and a stony crust. Achondrites come from the outer crust; stony-iron meteorites, from the inner crust; and iron meteorites, from the metallic core. Iron meteorites consist mostly of iron and nickel. Stony-iron meteorites have nearly equal amounts of silicon-based stone and iron-nickel metal.

The size of meteorites varies greatly. Most of them are relatively small. The largest meteorite ever found weighs about 66 tons (60 metric tons). It fell at Hoba West, a farm near Grootfontein, Namibia. However, much larger bodies, such as asteroids and comets, can also strike the earth and become meteorites.

Meteorites reach the earth's surface because they are the right size to travel through the atmosphere. If they are too small, they will disintegrate in the atmosphere. If they are too large, they may explode before reaching the earth's surface. One such object exploded about 6 miles (10 kilometers) above the Tunguska River in Siberia in 1908, leaving a 20-mile (32-kilometer) area of felled and scorched trees.

Thousands of small meteorites have been found in Antarctica, providing a rich supply of specimens for scientists to study. Scientists study meteorites for clues to the types of material that formed the planets.

Impact craters and basins. When large bodies such as asteroids and comets strike a planet, they produce an *impact crater* or *impact basin.* Impact craters are bowl-shaped depressions that measure up to about 10 miles (25 kilometers) in diameter. They have shallow, flat floors and uplifted centers. Impact basins are larger, and inside their rims there are one or more rings on the planet's surface.

Scientists have found more than 120 impact craters and basins on the earth. One of the most famous, the Meteor Crater in Arizona, is about 4,180 feet (1,275 meters) across and 570 feet (175 meters) deep. It formed nearly 50,000 years ago when an iron meteorite weighing 330,000 tons (300,000 metric tons) struck the earth.

Most impact craters and basins larger than the Meteor Crater are heavily worn away or have been buried by rocks and dirt as the earth's surface changed. The largest known of these is the Chicxulub (pronounced *CHEEK shoo loob*) Basin centered in Mexico's Yucatán Peninsula. The diameter of the basin is about 190 miles (300 kilometers). Rock samples obtained by drilling into the basin indicate that an asteroid struck the earth there about 65 million years ago. This was about the time the last dinosaurs became extinct. The impact hurled much debris into the sky. Many scientists believe this debris caused climate changes that the dinosaurs could not survive.

Virgil L. Sharpton

Meteor Crater, also known as Barringer Crater, is a huge circular depression in the earth in north-central Arizona, (see **Arizona** [physical map]). It measures about 4,180 feet (1,275 meters) wide and 570 feet (175 meters) deep. It was formed about 50,000 years ago when a meteorite struck the earth.

In 1903, Daniel M. Barringer, a Philadelphia mining engineer, acquired the land and spent years mining for the iron meteorite that he believed lay beneath the crater floor. He never found it. Scientists believe the meteorite disintegrated upon impact. Meteor Crater Enterprises, which leases the land from the Barringer family, operates a visitors center at the site. Lay James Gibson

Meteorite. See Meteor.

Meteorology, *MEE tee uh RAHL uh jee,* is the study of the earth's atmosphere and the variations in atmospheric conditions that produce weather. Meteorologists measure precipitation and such conditions as wind, temperature, and humidity. They also collect and measure gases, such as ozone and carbon dioxide, that occur in the atmosphere. Meteorologists use the data they gather to study and predict weather and climate. The word *meteorology* comes from *Meteorologica,* the title of a book by the ancient Greek philosopher Aristotle. In this book, Aristotle included his explanations of various weather conditions.

Meteorologists can predict the weather as far ahead as a few days. Their forecasts include ranges of temperature and cloudiness, and the chances of rain or snow. A forecast may also warn of strong winds, floods, hail, or severe air pollution. When dangerous weather conditions, such as hurricanes, tornadoes, or blizzards, are ex-

pected, meteorologists work with government officials and the public to develop emergency plans.

Some forecasters work for government agencies. Others work in television or radio and for airlines and power companies. Some meteorologists act as private consultants to groups especially dependent on weather, such as farmers and builders.

Many meteorologists conduct research. Some work to improve the use of computers to predict the weather. Others develop observation instruments. Still others study the causes of such events as tornadoes and floods.

How meteorologists measure the atmosphere. Meteorologists gather information about the atmosphere from land, at sea, in the air, and even from outer space. They use a variety of instruments, including thermometers; *barometers,* which measure air pressure; and *hygrometers,* which measure humidity.

Meteorologists track severe storms with *Doppler radar,* which can detect changes in wind speed or direction. They also rely on reports of *storm spotters,* people who watch for storms. Ocean buoys record air and sea conditions. Specially equipped aircraft and weather balloons provide data that meteorologists use to determine the temperature and humidity of the air and the speed and direction of winds. Meteorologists use weather satellites to follow storms and to estimate wind speeds. They also use data gathered by satellites to estimate temperature and humidity and to measure ozone.

Computer modeling. Meteorologists make extensive use of *computer models* to predict the weather. A computer model, sometimes called a *numerical weather prediction model,* is a set of mathematical equations processed by computers. The equations *simulate* (represent) how weather systems form and change.

A simulation begins with the current state of the atmosphere, as determined by the most recent observations. First, the computer predicts the state of the atmosphere after a specific time interval—for example, the next 90 seconds. Using the new state as a starting point, the computer then makes a forecast for 90 seconds later. This process repeats until the computer has produced forecasts for the next 12, 24, 36, and 48 hours. Computer models also produce weather maps.

History. Scientific observation of the weather began in 1593, when the Italian astronomer and physicist Galileo invented a thermometer to measure air temperature. By the late 1700's, people had invented instruments to measure humidity, wind speed, air pressure, and precipitation. During the 1800's, scientists used weather maps to forecast the weather.

In the early 1900's, meteorologists began to explain the structure of the atmosphere. The Norwegian meteorologist Vilhelm Bjerknes discovered that the atmosphere contains zones of rapidly changing conditions called *fronts.* In the late 1940's, the Swedish-American meteorologist Carl-Gustaf Rossby studied *jet streams,* which are atmospheric regions of extremely strong winds. Satellites became important in weather forecasting in the 1960's.

By 2000, meteorologists throughout the world had taken advantage of much improved technology. For example, extensive networks of Doppler radars helped forecast severe storms in the United States. Meteorologists also used powerful computers to quickly analyze data and make forecasts. Margaret A. LeMone

Meter, also spelled *metre,* is the base unit of length in the metric system. Its symbol is *m.* A meter is equal to 39.370 inches. Scientists define the meter as the distance traveled by light in a vacuum during $\frac{1}{299,792,458}$ of a second. See also Centimeter; Metric system.

Meter, in poetry, refers to the pattern of rhythm in a poem. The pattern may be easy or difficult to hear. Poets who create meters in English usually work within one of three metrical traditions: (1) stress, (2) syllabic, or (3) foot-verse. For a discussion of meter and examples of the most important meters, see Poetry (Rhythm and meter).

Meter is not necessary to poetry. In many poems, the rhythm does not create a pattern (see Free verse). The rhythm of such poetry often follows the structures of phrases and clauses, and the arrangement of lines on the page. Paul B. Diehl

See also Blank verse; Couplet.

Meter, Electric. See Electric meter.

Methadone is a drug used in experimental programs that help people overcome addiction to such narcotics as heroin, morphine, or opium. Most of these programs also include counseling to help addicts with psychological, social, and occupational problems.

Methadone itself can cause addiction with symptoms similar to those of heroin addiction. But if people already addicted to heroin, morphine, or opium take methadone, they no longer crave or even enjoy the other drugs. Methadone must be taken orally to produce those effects. If methadone doses are stopped, former drug cravings return. As a result, a former heroin addict may have to take methadone for life.

Lengthy methadone treatment has been criticized as a substitution of one addiction for another. But methadone therapy produces different effects than does addiction to heroin. A heroin user experiences *highs* (extremely happy feelings), dreamlike states, and sleepiness. Most heroin addicts cannot hold a job or maintain normal social relationships. But a former heroin addict who takes methadone in the prescribed manner has a clear mind and a feeling of well-being. In time, most addicts who are treated with methadone can lead normal lives. Long-term methadone therapy was developed in 1964 by two American physicians, Vincent Dole and Marie Nyswander. Donald J. Wolk

Methamphetamine, *MEHTH am FEHT uh meen,* is a powerful drug nicknamed "speed." It quickly produces feelings of joy, strength, and alertness. Methamphetamine gives a user the capacity to work and talk for long periods of time. Misuse of this drug can be dangerous, and it can be obtained legally only with a doctor's prescription. Methamphetamine is one of a group of drugs called amphetamines. It has been sold under many brand names, including Methedrine and Desoxyn.

Doctors once prescribed methamphetamine pills for weight control. The pills have also been used to combat fatigue and to help people under tension improve their work. Excess use of methamphetamine causes severe weight loss, pains in muscles and joints, excessive activity, and overconcentration on minor tasks. Some people become suspicious and develop antisocial behavior.

People who stop using methamphetamines may experience withdrawal symptoms. Such an experience suggests that the drug may cause physical dependence. In time, tolerance to the drug develops and the user's body needs larger and larger doses to achieve the same effect. Users may become mentally dependent on the drug if, when they go without it, they find the world cold and demanding. Sudden withdrawal from methamphetamines may cause deep depression, fatigue, or even a temporary *psychosis* (severe mental illness).

Methane, *METH ayn,* is an important industrial compound that makes up a large part of natural gas. It is formed when plants decay in places where there is very little air. Methane is often called *marsh gas* because it is found around stagnant water and swamps. It is also the chief substance in *firedamp,* a gas that causes serious explosions in mines.

The chemical industry uses methane as a starting material for many other chemicals. Methane reacts at high temperatures with a limited amount of air to form acetylene and with ammonia to produce hydrogen cyanide. It also undergoes *partial combustion* (incomplete burning), producing hydrogen and carbon monoxide gases. This mixture serves as a source for commercial hydrogen, and for carbon monoxide used in making methyl alcohol (methanol).

Methane is a colorless, odorless gas. It is nontoxic but highly flammable. It is soluble in alcohol but only slightly soluble in water. Methane's chemical formula is CH_4, and it is the first member of the *paraffin* series of hydrocarbons. Mixtures of methane with air, oxygen, or chlorine are explosive. Methane is a significant part of the atmospheres of Jupiter, Saturn, Neptune, and Uranus.

Robert C. Gadwood

See also **Acetylene; Damp; Gas** (The composition of natural gas); **Hydrocarbon; Methanol.**

Methanol, *METH uh nohl* or *METH uh nahl,* is a type of alcohol used for many industrial purposes. It is also called *methyl alcohol* or *wood alcohol.* Methanol is a clear, colorless organic compound. It is flammable and highly poisonous. Drinking methanol, or inhaling its fumes for prolonged periods, can cause blindness or death. Methanol also can be absorbed through the skin.

Methanol's chemical formula is CH_3OH. It has a molecular weight of 32.04. It boils at 65 °C and freezes at −94 °C. At 20 °C, its density is 0.7915 grams per cubic centimeter (see **Density**).

Methanol readily dissolves a number of other chemicals. This makes it an important *solvent* (substance that dissolves other substances) in the manufacture of dyes, medicines, and other products. Methanol also mixes readily with water. Solutions of methanol and water function in motor vehicles as antifreezes for windshield washer fluids and fuel lines. Such solutions remain liquid at temperatures that would freeze pure water.

A wide variety of products are manufactured from mixtures of methanol and *ethanol,* which is also called *grain alcohol.* Ethanol is an ingredient of many alcoholic beverages, but mixing it with methanol makes it *denatured* (unfit to drink).

A variety of substances undergo chemical reactions with methanol. For example, oxygen reacts with methanol to produce *formaldehyde,* a chemical used in making plastics. Organic acids react with methanol to form compounds called *esters,* which are used in such products as paints and varnishes. In addition, methanol can be converted to high-octane gasoline, but only by means of an expensive process.

Campers use methanol as fuel in portable stoves. Methanol also can function as a motor fuel in place of gasoline, but its rates of corrosion and combustion differ from those of gasoline. Therefore, such use of pure methanol requires adjustments to the carburetor, other engine parts, and the fuel tank.

Most commercial methanol is produced by heating carbon monoxide and hydrogen under pressure in the presence of a metal oxide catalyst (see **Catalysis**). Mixtures of carbon monoxide and hydrogen can be obtained from such sources as coal, natural gas, petroleum, wood, garbage, or sewage. Robert C. Gadwood

Method acting is the general approach to acting used by many modern American actors. This approach is based upon the idea that actors should achieve a detailed emotional identification with their characters. Actors try to think and feel what their characters would think and feel. Method acting tries to help actors create truthful and deeply felt performances.

The major features of Method acting are taken from the teachings of Russian stage director Konstantin Stanislavski. In 1931, the Group Theatre was organized in New York City by Harold Clurman, Lee Strasberg, and Cheryl Crawford. Using Stanislavski's ideas, the Group developed acting techniques over 10 years marked by lively experimentation and passionate debate. In 1947, several former members of the Group founded the Actors Studio as a place where professional actors could continue to refine their skills. Under Strasberg's direction, the Actors Studio became the most influential American home of Method acting.

Robert Lewis helped to found Actors Studio. His book *Method—or Madness?* (1958) describes many exercises and techniques of Method acting. Maarten Reilingh

Methodists belong to those Protestant denominations that trace their beginnings back to John Wesley, a clergyman of the Church of England. A number of churches throughout the world share the name *Methodist* and a common heritage in Wesley's teaching and organization. The largest is The United Methodist Church, which is predominantly North American. There is no central organization of Methodists, but many denominations are part of the World Methodist Council, a cooperative association. Methodists have followed John Wesley in adopting the teachings and practices of the Church of England. They accept the Bible as the primary rule of faith, with Christian tradition and reason as secondary authorities. They also stress religious experience as an important standard of faith.

Early history. Methodism originated as a movement with groups of students at Oxford University in the late 1720's. They helped each other to be disciplined and methodical in their study, spiritual devotions, and practical good works. These activities earned them the nickname "Methodists." One of the founders was Charles Wesley, and their leader was his brother John. Both

brothers, after deep personal experiences of faith in 1738, joined the Evangelical Revival of the 1700's by venturing into open-air preaching.

There were two distinctive features of the Wesleys' preaching and the Methodist movement. The first was a message that invited all to respond to God's gracious reconciliation through Jesus Christ. The second was the incorporation into societies of those who did respond. In the societies, members developed the practical disciplines of a Christian life, primarily through subdivisions of the societies, known as *classes.* Classes met weekly under the spiritual guidance of a class leader, who asked members to give an account of their discipleship according to the General Rules of the Societies (1743).

As the movement spread, John Wesley emerged as its leader and Charles as its poet. Charles composed more than 7,000 hymns, giving Methodists a further distinctive characteristic—the singing of their faith. The *Collection of Hymns* (1780) remains a spiritual classic of the world church. John's major role was to organize the societies into a connected system governed by an annual conference that first met in 1744. Methodism was also noted for John's use of *lay* (unordained) preachers.

John Wesley wanted the societies to remain a reforming movement within the Church of England. However, the resistance of Anglican clergy and the need to provide pastoral supervision for society members led to a separation from the church. Wesley acknowledged this separation in 1784, when he ordained Thomas Coke as the first superintendent of the Methodist church in America. He also gave Coke authority to ordain Francis Asbury to serve in the same capacity.

In 1784, at the Christmas Conference in Baltimore, the Methodist Episcopal Church was formed, with Coke and Asbury becoming its first bishops. The new denomination spread rapidly, chiefly through the work of traveling preachers, known as *circuit riders,* who took Methodism's message to the expanding American frontier.

Social change and division. As Methodism became consolidated, the discipline of the early societies gave way to the less demanding social structure of a church. Tensions developed, some of which were due to unresolved issues of church government following John Wesley's death in 1791. But the deeper reason for the tensions was that Methodism stressed a Christian lifestyle in the world. This emphasis involved its members in the social changes of the 1800's. In England, the major social conflict was the emerging trade union movement. In the United States, it was slavery.

These issues led to many divisions among the Methodists. In the United Kingdom, the first was the formation of the Methodist New Connexion in 1797, which was followed by the Primitive Methodists in 1810. In the United States, the divisions resulted in the establishment of the Methodist Protestant Church (1830), the Wesleyan Methodist Connection (1843), and the Free Methodist Church (1860). Several black Methodist churches were also formed, including the African Methodist Episcopal Church (1787), the African Methodist Episcopal Zion Church (1796), and the Colored (later the Christian) Methodist Episcopal Church (1870). The most important dispute over slavery occurred in 1844, dividing the Methodist Episcopal Church into North and South denominations. Doctrinal differences led to the formation of the Church of the Nazarene (1908).

Major reunions took place in the United Kingdom in 1932 and in the United States in 1939. The United Methodist Church was formed in 1968. Methodists became part of the United Church of Canada in 1925, and the Uniting Church in Australia in 1977. David Lowes Watson

Methuselah, *muh THOO zuh luh,* was the son of Enoch, the father of Lamech, and the grandfather of Noah in the Old Testament. According to the Bible, he lived 969 years (Gen. 5:25-27), making him the oldest Biblical person. The expression "as old as Methuselah" describes a very old person. Babylonians believed some of their heroes lived 36,000 years. Carole R. Fontaine

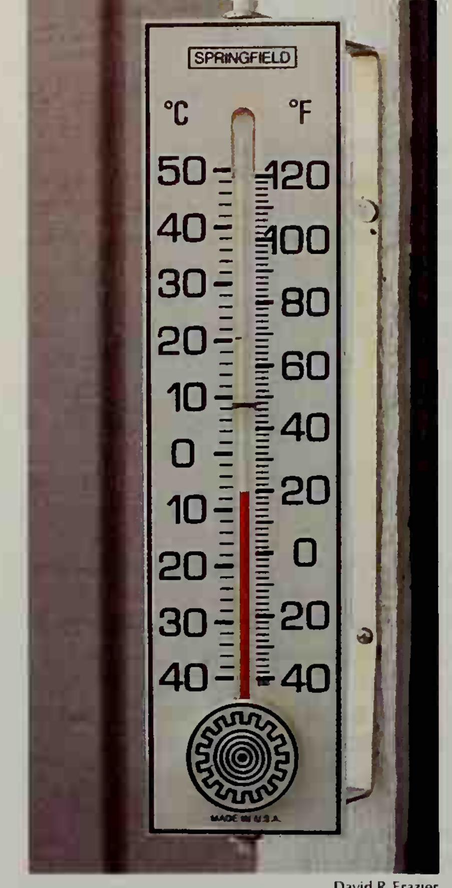
Métis, *may TEES* or *may TEE,* refers to people of mixed white and American Indian ancestry. Métis culture developed primarily in the Red River Colony (in present-day Manitoba) in the 1800's. The word *métis* comes from an old French word that meant *mixed.*

Métis settlements developed in the Red River Colony from contacts between Indians and colonial fur-trading companies. Métis settlers farmed and traded furs, but they primarily hunted buffalo. Several culturally distinct métis groups lived in the colony, including French-speaking Roman Catholics and English-speaking Protestants. Most métis also spoke the Cree Indian language, and eventually many spoke a dialect that was a mixture of French and Cree.

The métis rebelled in 1869-1870, after Canada's government prepared to move white settlers into the Red River area. The area became part of Canada in 1870.



Over the next several years, the government systematically forced the métis off their land. Many English-speaking métis merged into nearby white communities. But most métis moved to what is now Saskatchewan.

In Saskatchewan, métis again battled the Canadian government, this time in the North West Rebellion of 1885. After the rebellion failed, many métis in Saskatchewan mixed into white communities. Today, many people of partial Indian ancestry in Canada and in certain border areas of the United States refer to themselves as métis. J. M. Bumsted

Metonymy, *muh TAHN uh mee,* is a figure of speech by which a phrase or word is used for a related phrase or word. For example, when we "turn on the light," we actually flip a switch, closing an electric circuit and causing the light. But we give the name of the effect to the cause. When we "listen to recordings," we really hear music, but we name the cause to mean the effect. See also Slang (Figures of speech).

Metric units are used for everyday measurements in most countries. Many product labels and public signs show both the metric measurement and its equivalent in the inch-pound system.

Metric system

Metric system is a group of units used to make measurements in science and engineering, in commerce, and in everyday life. The original metric system was adopted by France in 1795. The modern system, called the International System of Units, is a modified version of that system. People commonly refer to the modern system by the initials SI, which stand for its name in French—*Système International d'Unités.* Representatives from throughout the world meet every four years at a General Conference on Weights and Measures (CGPM) to deal with matters concerning SI.

SI is the main system of measurement in all the technologically advanced nations of the world except the United States. Scientists and many engineers in the United States use SI. For most commercial and everyday measurements, however, Americans use the *inch-pound system.* Inch-pound units entered what is now the United States in the 1600's, when the English began to settle along the Atlantic coast of North America.

Kinds of metric units

SI is a *comprehensive* system of measurement, one that has units for all measurable properties of physical objects and processes. An example of a measurable property of an object is the length of a city block: A block might be 200 meters long. The *velocity* (speed) of a moving object is an example of a measurable property of a process: A baseball pitched by a major-league professional might travel at a velocity of 40 meters per second. Scientists refer to measurable properties as *physical quantities,* or simply *quantities.*

SI units are related to one another in a simple, logical way that makes the metric system easy to use. Seven *base units* serve as the "building blocks" from which all the other units are constructed. For example, the meter is the base unit used to measure length, and the second is the base unit to measure time. *Derived units* are built up from base units. *Meter per second* is an example of a derived unit. Base units and derived units together are known as *SI units.*

Multiples and *submultiples,* in turn, are built from SI units. A multiple is larger than the SI unit from which it is built. For example, the *kilometer,* a multiple of the meter, is 1,000 times as large as the meter. A submultiple is smaller than its SI unit. The *millimeter,* a submultiple of the meter, is $\frac{1}{1,000}$ the size of the meter.

Every unit in SI has a symbol. For example, the symbol for meter is m. The SI symbols are not ordinary abbreviations. They are not written with a period, except at the end of a sentence; they are the same in singular and plural; and they are the same in all languages.

Advantages of the metric system

Four features help make SI easy to use and give it an advantage over the inch-pound system: (1) Only one "family" of units—one SI unit and its multiples and submultiples—is needed for all measurements of any one quantity, (2) SI uses the decimal system for building multiples and submultiples, (3) SI uses standard prefixes for naming multiples and submultiples, and (4) units used to measure different quantities are related in a simple way. The inch-pound system has none of these features.

Bruce B. Barrow represents the Institute of Electrical and Electronics Engineers, Incorporated, on the committee that maintains the primary American National Standard on metric practice.

Use of one "family" of units per quantity. An example of the first feature is the use of the "meter family" to measure length. People use the meter to measure large distances, such as the lengths of athletic fields and the heights of mountains. To measure the distance between cities, people use the kilometer. The *centimeter,* which is $\frac{1}{100}$ the size of the meter, is used to measure such quantities as the length of a pencil and the height of a person. The millimeter is useful for measuring such small objects as coins and computer chips.

Use of decimal multiples. An SI unit is related to its multiples and submultiples by factors of 10. For example, the kilometer differs from the meter by three factors of 10: It is $10 \times 10 \times 10 = 1{,}000$ times as long as the meter. The centimeter differs from the meter by two factors of 10: A centimeter is $\frac{1}{10} \times \frac{1}{10} = \frac{1}{100}$ of a meter.

This use of decimal multiples makes it easy to convert from one unit to another unit in the same "family" of units. For example, to convert meters to kilometers, you would divide by 1,000, merely shifting the decimal point three places to the left. Thus, 4,356 meters would convert to 4.356 kilometers.

Use of standard prefixes. The third helpful feature of SI appears in the use of the prefixes *kilo, centi,* and *milli* in our examples. These are standard SI prefixes. Attaching them to any SI unit multiplies the value of that unit by 1,000, $\frac{1}{100}$, and $\frac{1}{1{,}000}$, respectively. For example, attaching *kilo* to the *watt,* the SI unit for power, creates the *kilowatt,* which equals 1,000 watts. Attaching *milli* creates the *milliwatt,* equal to $\frac{1}{1{,}000}$ watt.

Use of related units. The simple relationships between the "families" of units for length, area, and volume illustrate the fourth helpful feature. The meter is the base unit for all three families. The "meter family" is for measuring length. To measure area, you can use the square meter, square kilometer, square millimeter, and other members of the "square meter family." The cubic meter, cubic kilometer, cubic millimeter, and other members of the "cubic meter family" are for measuring volume.

The inch-pound system has no decimally related multiples and submultiples. In most cases, that system offers a choice of different-sized units for measuring a single quantity. To measure length, for example, you can choose, in order of increasing size, the inch, the foot, the yard, or the mile. But the factors relating these units to one another are difficult to use in making conversions. There are 12 inches in a foot, 3 feet or 36 inches in a yard, and 1,760 yards or 5,280 feet in a mile. Furthermore, the names of the units provide no clue to their numerical relationships.

Structure of the metric system

SI extends the systematic approach of the early metric system. Over the years, the CGPM has chosen certain physical quantities as *base quantities.* For each base quantity, the CGPM has defined an SI base unit. It has then derived other quantities using multiplication and division, leading to the creation of corresponding SI derived units. The CGPM has given special names to some important derived units.

SI base units are (1) the meter; (2) the *kilogram,* which is the unit for *mass* (amount of matter); (3) the second, for time; (4) the *ampere,* for electric current; (5) the *kelvin,* for temperature; (6) the *candela* (pronounced *kan DEHL uh),* for the brightness of light; (7) and the *mole,* for *amount of substance,* a term used in chemistry.

The remainder of this section discusses the structure of SI as the system is applied in six areas: (1) space and time, (2) mechanics, (3) heat, (4) electricity, (5) light, and (6) chemistry.

Space and time. Length is the base quantity for space measurement, and the meter is the base unit. The area of a rectangle is its length times its width. So the derived unit of area is the product of the unit of length and the unit of width. This product is *meter times meter,* or *square meter*—in algebraic notation, m^2. Thus, the area of a floor that measures $3\ m \times 5\ m$ is $15\ m^2$.

When a prefix is used in an area measurement, the prefix is squared also. Thus, a square centimeter (cm^2) is a square that is 1 cm on a side. The area of this square in square meters is $0.01\ m \times 0.01\ m$, or $0.0001\ m^2$.

The volume of a rectangular object is the product *length times width times height*—three length quantities. Thus, the SI derived unit for volume is the cubic meter, m^3. The volumes of everyday objects, such as a refrigerator or a gasoline tank, are measured in *cubic decimeters.* A cubic decimeter (dm^3) is equivalent to a cube that is 1 dm on a side, and 1 dm equals 0.1 m. Therefore, the volume of a cubic decimeter is $0.1\ m \times 0.1\ m \times 0.1\ m$, or $0.001\ m^3$.

For the measurement of time, the second (s) is the base unit. Races in a track meet are sometimes won by milliseconds. Calculations in a personal computer are performed in *microseconds* (millionths of a second).

Because velocity or speed is distance traveled divided by the time required, the derived unit for velocity is meter per second (m/s). A sprinter can achieve a speed of 10 m/s over a short distance.

Acceleration is a change in velocity during a period of time. The SI derived unit for acceleration is therefore the unit of velocity divided by the unit of time—meter per second squared (m/s^2).

Frequency measures how often a regularly repeating event occurs over time. Frequency is measured in *cycles* (repetitions) per second, a unit that has been given the special name *hertz* (Hz). Many computers run at 500 megahertz or higher, which means that the electronic clock that is timing the computer's operations is "ticking" 500 million times a second.

Mechanics deals with such questions as why moving objects move as they do, and how buildings and bridges support weight. These kinds of questions involve mass and force.

Mass is an SI base quantity, and its unit is the kilogram (kg). One kilogram is almost exactly the mass of 1 liter of water. In everyday language, mass is usually called *weight,* as in the statement, "My weight is 80 kilograms." Most adults weigh between 50 and 100 kg. Groceries are measured in grams and kilograms, while most medicines are measured in milligrams.

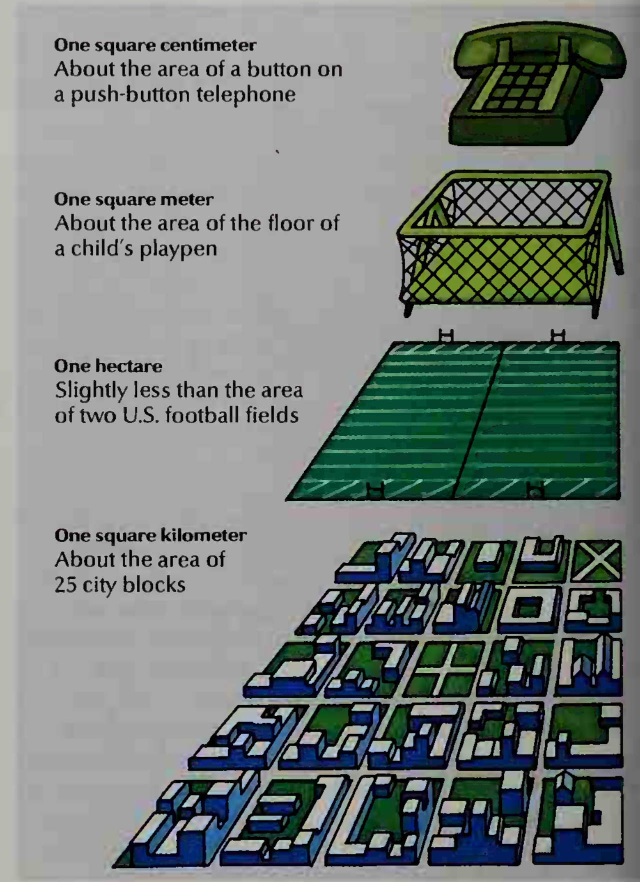
The kilogram is the only base unit whose name includes a standard prefix. The CGPM had the option of choosing the *gram,* equal to $\frac{1}{1{,}000}$ kilogram, as a base unit. It chose the kilogram instead because the gram is such a small unit—a dollar bill has a mass of about 1 gram. When units larger or smaller than the kilogram are needed, one must attach prefixes to *gram.*

The metric system at a glance

Length and distance

Length and distance measurements in the metric system are based on the meter. All units for length and distance are decimal fractions or multiples of the meter. Commonly used units include the millimeter, centimeter, meter, and kilometer.

One millimeter
About the thickness of a paper match

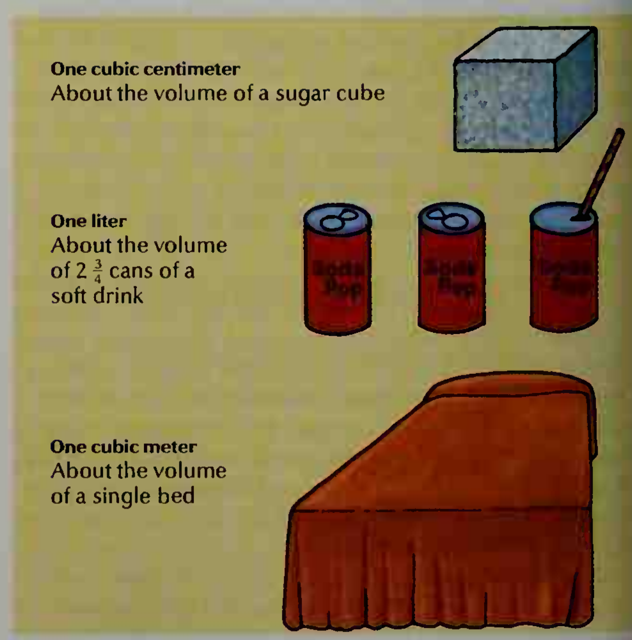


One centimeter
About the radius of a United States nickel

One meter
About the length of four volumes of the *World Book* placed top-to-bottom

One kilometer
About the length of five city blocks

Surface or area

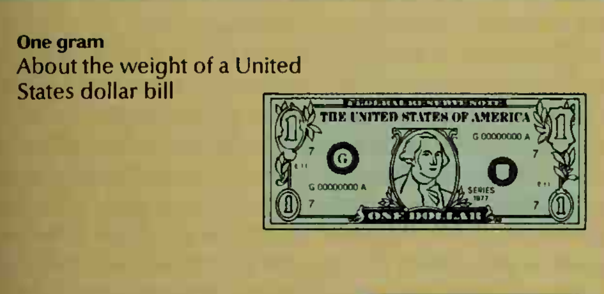


Surface or area measurements in the metric system are also based on the meter. But area is measured in square units. Common area units include the square centimeter, square meter, hectare (10,000 square meters), and square kilometer.

WORLD BOOK illustrations by George Suyeoka

Volume and capacity

Volume and capacity measurements in the metric system are based on the meter, but these measurements are made in cubic units. Common volume and capacity units include the cubic centimeter, liter (1,000 cubic centimeters), and cubic meter.



The illustrations on these pages help show the size of the most common metric units. The metric conversion table will aid in the conversion of measurements into or out of the metric system.

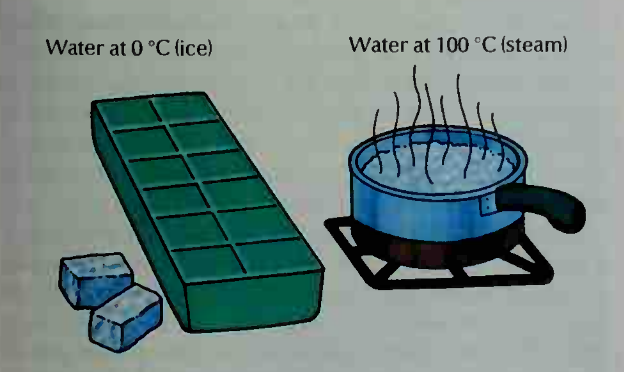
Weight and mass

Mass is the amount of matter an object contains. In everyday language, mass is usually called *weight.* The base unit for mass in the metric system is the kilogram. Commonly used metric units of mass, besides the kilogram, include the gram (0.001 kilogram) and the metric ton (1,000 kilograms).

One gram
About the weight of a United States dollar bill

One kilogram
About the weight of the U-V volume of *World Book*

One metric ton
About the weight of a small automobile



Metric conversion table

When you know:	Multiply by:	To find:

degrees Fahrenheit (°F)	$\frac{5}{9}$ (after subtracting 32)	degrees Celsius*
degrees Celsius (°C)	$\frac{9}{5}$ (then add 32)	degrees Fahrenheit*

*Answer is exact.

Temperature

Everyday temperature measurements in the metric system are made on the Celsius scale. This scale was formerly called the centigrade scale. Water freezes at 0 °C and boils at 100 °C.

Metric prefixes

These prefixes can be added to metric units to increase or decrease their size. For example, 1 kilometer equals 1,000 meters. The spelled-out numbers above 1 million and below one-millionth represent usage in the United States.

Prefix	Symbol	Increase or decrease in unit	
yotta *(YAH tuh)*	Y	1,000,000,000,000,000,000,000,000	(One septillion)
zetta *(ZEH tuh)*	Z	1,000,000,000,000,000,000,000	(One sextillion)
exa *(EHK suh)*	E	1,000,000,000,000,000,000	(One quintillion)
peta *(PEH tuh)*	P	1,000,000,000,000,000	(One quadrillion)
tera *(TEHR uh)*	T	1,000,000,000,000	(One trillion)
giga *(GIHG uh)*	G	1,000,000,000	(One billion)
mega *(MEHG uh)*	M	1,000,000	(One million)
kilo *(KIHL uh)*	k	1,000	(One thousand)
hecto *(HEHK tuh)*	h	100	(One hundred)
deka *(DEHK uh)*	da	10	(Ten)
deci *(DEHS uh)*	d	0.1	(One-tenth)
centi *(SEHN tuh)*	c	0.01	(One-hundredth)
milli *(MIHL uh)*	m	0.001	(One-thousandth)
micro *(MY kroh)*	µ	0.000001	(One-millionth)
nano *(NA noh)*	n	0.000000001	(One-billionth)
pico *(PY koh)*	p	0.000000000001	(One-trillionth)
femto *(FEHM toh)*	f	0.000000000000001	(One-quadrillionth)
atto *(AT toh)*	a	0.000000000000000001	(One-quintillionth)
zepto *(ZEHP toh)*	z	0.000000000000000000001	(One-sextillionth)
yocto *(YAHK toh)*	y	0.000000000000000000000001	(One-septillionth)

Force is a push or a pull. A force tends to cause a body to move, or a body that is in motion to change its motion. A force is equal to the product of the mass that it accelerates and the acceleration. The derived unit for force is therefore the unit of mass times the unit of acceleration, kilogram meter per second squared. This SI unit has the special name *newton* (N). To feel a newton, lift a small apple or a lemon. The force of gravity on the fruit will be roughly 1 newton.

Pressure is force per unit area. The SI derived unit is the newton per square meter, which has the special name *pascal* (Pa). Atmospheric pressure at sea level is about 100 kilopascals.

Work occurs when a force acts through a distance, and it is the product of force and distance. The SI derived unit for work is the newton meter, given the special name *joule* (J). *Energy,* which is the capacity for doing work, is measured in the same unit.

A closely related quantity is *power,* which is energy divided by time. The SI derived unit is joule per second, which has the special name *watt* (W). As a unit of electric power, the watt is one of the most familiar SI units. It is also the proper unit to use in expressing mechanical power. The *horsepower,* an inch-pound unit of mechanical power, equals about 750 watts.

Heat is a form of energy, and so it is measured in joules. Temperature is the base quantity needed to study heat, and its SI base unit is the kelvin (K). A more familiar name given to the same unit is *degree Celsius* (°C). The Celsius scale is used for everyday measurements in the metric system.

Although the kelvin and the degree Celsius are the same size, the scales in which they are used have different zero points. The zero point of the kelvin scale is the coldest possible temperature, a point that is called *absolute zero.* The zero point of the Celsius scale is the freezing point of water. The size of the temperature unit is such that 0 K = −273.15 °C, and 0 °C = 273.15 K. At sea level, water boils at a temperature of 100 °C. Normal body temperature for human beings is about 37 °C.

Electricity. Electric current, motion of electric charge, is the base quantity for electricity. The corresponding base unit is the ampere (A). When 1 ampere flows for 1 second, the amount of charge moved is equal to 1 ampere second. The SI derived unit *ampere second* has the special name *coulomb* (C). The electromotive force that is required to move charges is known as *voltage,* and it is measured in a derived unit called the *volt* (V).

The ampere, the coulomb, and the volt have direct relationships to the SI units for work and power. If 1 coulomb of charge moves through a voltage difference of 1 volt, 1 joule of work is done on the charge. If a current of 1 ampere is flowing, then work is occurring at a rate of 1 joule per second, which is a power of 1 watt.

Electric power is the product of voltage and current. In homes in the United States, the voltage at ordinary electrical outlets is about 110 volts. For this voltage, the power equation "volts times amperes equals watts" shows that the current in a 100-watt light bulb will be a little less than 1 ampere.

Light. The base quantity for the measurement of illumination is *luminous intensity,* the brightness of light. The corresponding SI base unit is the candela (cd). The candela is defined in terms of the rate at which light energy flows from the source of the light. An ordinary candle has an intensity of roughly 1 candela.

The derived quantity *luminous flux* is the rate at which light energy falls on a surface. The derived unit for this quantity is the *lumen* (lm). A surface that is 1 square meter in area, placed 1 meter away from a source of 1 candela, receives 1 lumen. Light bulbs are rated in terms of the number of lumens they produce.

Chemistry is the study of the interactions of the atoms and molecules that make up material substances. Chemists use a base quantity called *amount of substance* that enables them to relate the number of individual atoms or molecules in one system to that in another. In this case, the word *system* refers to a set of elementary objects that are to be studied in an experiment or used in a reaction. The objects may be atoms, molecules, electrons, or other subatomic particles.

The SI unit for amount of substance is the mole (mol), and it is defined so that 1 mole of the most common form of carbon atoms weighs exactly 12 grams. One mole of any other substance will contain the same number of elementary objects as 1 mole of such carbon atoms. For example, 1 mole of atoms of carbon (chemical symbol C) combines with 1 mole of oxygen molecules (O_2) to form 1 mole of carbon dioxide (CO_2).

Chemical engineers determine the number of moles in a system by measuring its mass—that is, by weighing it—because it is not practical for them to count atoms or molecules. The masses of different atoms and molecules have been measured, and they may be compared by using a number called the *relative atomic mass* or the *relative molecular mass.* By international agreement, the relative atomic mass of the most common form of carbon is exactly 12, so 1 mole of it weighs 12 grams. The relative molecular mass of O_2 is very close to 32, and therefore 1 mole of O_2 would weigh very close to 32 grams.

Non-SI metric units. People still use many old metric units that are not a part of SI. The international authorities that set standards for the use of SI consider only a few such units to be acceptable for general use. These units include the *liter,* the *metric ton,* and the *hectare.*

The liter is a unit of volume equal to a cubic decimeter. Its symbol is L or l. Metric authorities in the United States prefer to use capital "L" because the lower-case letter resembles the number "1" in many kinds of type.

The metric ton is a unit of mass equal to 1,000 kilograms. The hectare (ha) is a unit of area used for measuring land. One hectare equals 10,000 square meters.

According to international agreement, most other non-SI metric units should be avoided. These include the *calorie* for energy (use joules), the *millimeter of mercury* for pressure (use pascals), and the *kilogram-force* or the kilogram used as a unit of force (use newtons). Also to be avoided are derived units from older metric systems that use the centimeter, gram, and second as base units. Among these units are a force unit called the *dyne* and a unit of acceleration known as the *gal.*

Selection of SI prefixes. Although any SI prefix may be attached to any SI unit, the prefixes *centi, deci, deka,* and *hecto* find limited use. An important exception is the *centi* in *centimeter,* which is a very useful unit for many purposes. The deciliter, dekaliter, and hectoliter are all of practical size and are used in household and commercial measurements. The decimeter, dekameter, and

hectometer appear in some special places such as maps and nautical charts. The square decimeter, square dekameter, and square hectometer are useful for measuring areas; the cubic decimeter, cubic dekameter, and cubic hectometer, for measuring volumes.

History

During the 1600's and 1700's, many people recognized the need for a measurement system that would be widely agreed upon and easy to use. At that time, different countries used their own systems, and there were many differences in units of measure within a single nation. Merchants found the lack of a universal system of measure inconvenient, especially as their markets expanded. A cloth merchant, for example, might deal with suppliers and customers who used several units of length measurement. The pace of scientific discovery was increasing as well. Scientists needed a universal system to help them share theories and experimental data with colleagues in other countries.

Creation of the metric system. In 1790, the National Assembly, the parliament of France, took action. The Assembly asked the French Academy of Sciences to work out a system of units suitable for adoption by the entire world. The next year, the Academy proposed a system based on a single unit of length measurement. This unit would be based in nature. It would be one ten-millionth of the distance from the North Pole to the equator.

The designers of the system defined the fundamental unit of mass in terms of the length unit, which they named the meter. The new unit of mass, the gram, would be equal to the mass of 1 cubic centimeter of water at a specified temperature. It followed from the definition that a liter of water, which contains 1,000 cubic centimeters, would weigh 1 kilogram. This meant that anybody, anywhere, who had a meter measuring stick could also develop a practical standard for weighing objects. Thus, the early metric system used one unit, the meter, to tie together in a simple, systematic way the units for length, area, volume or capacity, and mass.

France adopted the metric system in 1795. A survey carried out in France established the length of the meter. Physical models of the meter were cast for comparison with measuring sticks. A bar of platinum was chosen as the standard meter and was stored in Paris.

Evolution of the metric system. Formal international standardization of the metric system began in 1875, when 17 nations, including the United States, signed a document called the Treaty of the Meter. This document established an international framework for maintaining the metric system.

At that time, the metric system had no units for electricity or magnetism. But the British Association for the Advancement of Science (BAAS) had proposed such units a year earlier. These units were derived from the *CGS system,* which has the centimeter, gram, and second as base units. In the 1880's, the BAAS and an organization called the International Electrical Congress approved a set of *practical units* for electricity and magnetism. These included the ampere and the volt.

In 1889, the CGPM selected a physical standard for the kilogram. The kilogram became the mass of a particular weight, made of platinum and iridium, known as the *international prototype kilogram.* All standard weights in the world, including those for pounds and ounces, are still related to this standard. At the same time, the CGPM selected one standard bar, also made of platinum and iridium, to define the meter.

In 1939, the International Electrotechnical Commission, successor to the International Electrical Congress, recommended that the CGPM bring electrical units into its metric system. The resulting system would have four base units—the meter, the kilogram, the second, and the ampere. In 1954, the CGPM approved this recommendation. The CGPM also adopted two additional base units—the candela and the *degree Kelvin* (°K), which became known as simply the kelvin in 1967.

The CGPM named the "official" metric system the International System of Units in 1960. Also in 1960, the CGPM defined the meter in terms of the wavelength of light. The CGPM added the mole as a base unit in 1971, bringing the number of base units to the present seven.

Acceptance of the metric system. Although France officially adopted the metric system in 1795, the French government did not require its people to use the system until 1840. Other nations then began to adopt it. By 1850, the metric system was also the official system of measurement in Greece, the Netherlands, Spain, and parts of Italy. By 1900, most of the commercially advanced countries of the world had adopted it. The main holdouts were the United States and nations of the British Empire.

But by the early 1960's, the United Kingdom had drawn close to mainland Europe commercially. In 1965, the United Kingdom began a changeover to the metric system. New Zealand began to convert in 1969, Australia in 1970, and Canada in 1975.

In the United States, pharmacists had begun to use metric units to fill prescriptions in the 1950's. The Department of Defense and the National Aeronautics and Space Administration (NASA) began to use metric measurements. Major U.S. makers of automobiles and farm machinery changed to the metric system in the 1970's.

In 1975, the U.S. Congress passed a law establishing a policy of voluntary conversion to the metric system. Congress amended this law in 1988, naming the metric system the preferred system of weights and measures for U.S. trade and commerce. The amendment also called for federal agencies to use the metric system for purchases, grants, and other business-related activities.

By the early 2000's, almost all scientific work and an increasing amount of engineering work in the United States was done using metric units. Contractors designed and built most major highways and many federal buildings in metric units. Major industrial firms had converted their U.S. facilities to metric. Packaged groceries were labeled in metric units as well as inch-pound units. Many beverages and other consumer products were sold in metric-sized containers. Bruce B. Barrow

Metronome, *MEHT ruh nohm,* is an instrument that beats time for musicians. The Dutch inventor Dietrich Winkel invented it. But the German Johann N. Mälzel patented it in 1816. The mechanical type consists of a wooden or plastic box with a pendulum. A movable counterweight is attached to the pendulum. The mechanism ticks as the pendulum moves. The lower the counterweight is set, the faster the machine ticks. Most modern metronomes are small electronic devices. They may tick, display a flashing light, or both. Thomas W. Tunks

WORLD BOOK photo by Steinkamp/Ballogg

The metronome is a clocklike device with a pendulum that can be adjusted to make a ticking sound at various speeds. Metronomes mark time for people practicing on musical instruments.

Metropolitan is the title of a high-ranking clergyman in the Anglican, Eastern Orthodox, and Roman Catholic churches. He is the head of a church province, diocese, or all the Christians in an important city. Like archbishops, metropolitans rank above bishops. They consult with bishops about matters other than regular affairs in the bishop's diocese. A metropolitan also calls and presides over church councils called *synods.* In some Eastern Orthodox Churches, the head of an independent national church is called a metropolitan. See also **Archbishop; Patriarch.** Ralph W. Quere

Metropolitan area consists of a central city and the developed area that surrounds it. The developed area may be made up of such jurisdictions as cities, boroughs, towns, townships, or villages.

In the United States, a metropolitan area is officially called a *Metropolitan Statistical Area.* Two or more adjacent metropolitan statistical areas form a *Consolidated Metropolitan Statistical Area.* U.S. metropolitan areas have at least one city or urban area with a population of 50,000 or more, and include the entire county in which the city is located. Adjacent counties may be considered part of the area, depending on their population density and the number of workers who commute to jobs in the central county. The term *greater* applied to a city refers to a metropolitan area, such as Greater Paris. In England, clusters of small cities around a large city are called *metropolitan counties.*

In developed countries, most people live in metropolitan areas. In the United States, about 80 percent of the people live in the nation's 276 metropolitan statistical areas. In Canada, about 60 percent of the people reside in 25 metropolitan areas.

The development of suburbs

As cities grow, people move beyond official city boundaries, creating suburbs. This process of *suburbanization* has been going on since the late 1800's. Several factors contributed to the development of metropolitan areas. Originally, large numbers of people came from rural areas to central cities in search of employment. This population shift produced overcrowded cities, causing other people to move to outlying areas. The use of automobiles, together with the improvement of roads and highways, increased tremendously following the end of World War II in 1945. As a result, more and more people have settled in communities outside of central cities since the late 1940's. By 1970, more people in U.S. metropolitan areas lived in suburbs than in central cities.

Many people moved to the suburbs to avoid such problems of city life as crime, housing shortages, and racial conflicts. However, as the suburbs grew larger, they developed the same types of problems. These problems, as well as urban revitalization programs, persuaded some people to move back to central cities. Nevertheless, the total population of suburban areas continued to grow.

People who live in the suburbs of a central city have traditionally considered the city as their workplace because of its commercial and industrial activities. Suburbanites also use the city's cultural, professional, and recreational facilities and services. Since the 1950's, however, many businesses and industries have moved to the suburbs. Today, many suburbanites who once commuted to and from work in the city work, shop, and enjoy various recreational activities in the suburbs.

Problems of metropolitan areas

Government. Most metropolitan areas have no central government to handle problems that affect the entire area. In most cases, government is almost completely decentralized—that is, each city, town, village, or other community in the metropolitan area has its own government. Little or no relationship exists between these governments and that of the central city.

The metropolitan statistical areas in the United States contain such local governmental units as counties, townships, municipalities, school districts, and special

districts. Each unit has considerable political independence and establishes its own policies. As a result, government in most metropolitan areas is characterized by overlapping authority, policy conflicts, and lack of cooperation in solving mutual problems.

Many people who live in a metropolitan area may be affected by government policies over which they have little or no control. For example, people who live in suburbs may vote in their suburb and, at the same time, own a business in the central city. Government policy decisions made in the city may affect the business, even though the suburbanite cannot vote on them.

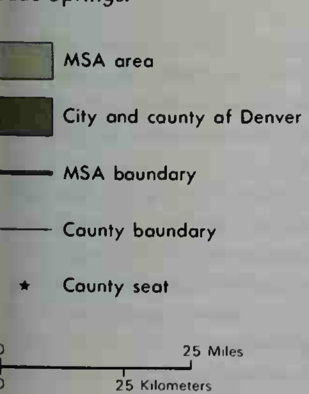
Finances and taxation. The widespread movement from central cities to suburbs affects the financial position of all the communities involved. The central city experiences declining land values and the loss of tax revenues. Also, many people who move into the city are poor, and many who move out are wealthy. As a result, the city provides medical care and other services for large numbers of residents who cannot afford them. The relocation of industries and commercial activities to the suburbs deprives city residents of job opportunities and reduces the city's tax base. However, many suburban communities are almost completely residential. Such suburbs have few taxable businesses, and they therefore often have difficulty raising enough money to provide adequate levels of such essential services as police and fire protection and public education.

Many suburban residents use public facilities in the central city, including museums, parks, and sports arenas, all of which require expensive maintenance. Some cities have tried to tax suburban residents who work in the city or to charge nonresident fees for the use of city facilities. In most cases, suburbanites have successfully resisted such taxes. Some suburbs have attempted to impose a similar tax on city dwellers who work in the suburbs or use suburban facilities. Most of these attempts also have failed.

Property taxes are the major source of revenue for governmental units within a metropolitan area. As a result, the central city and its suburbs compete for such tax-paying developments as manufacturing plants, office buildings, and shopping centers. These types of developments pay high property taxes and use few expensive public services. But in recent years, many metropolitan areas have worked to slow or stop suburban growth in order to reduce the cost of maintaining roads, sewage systems, and other public utilities and to protect the suburban way of life.

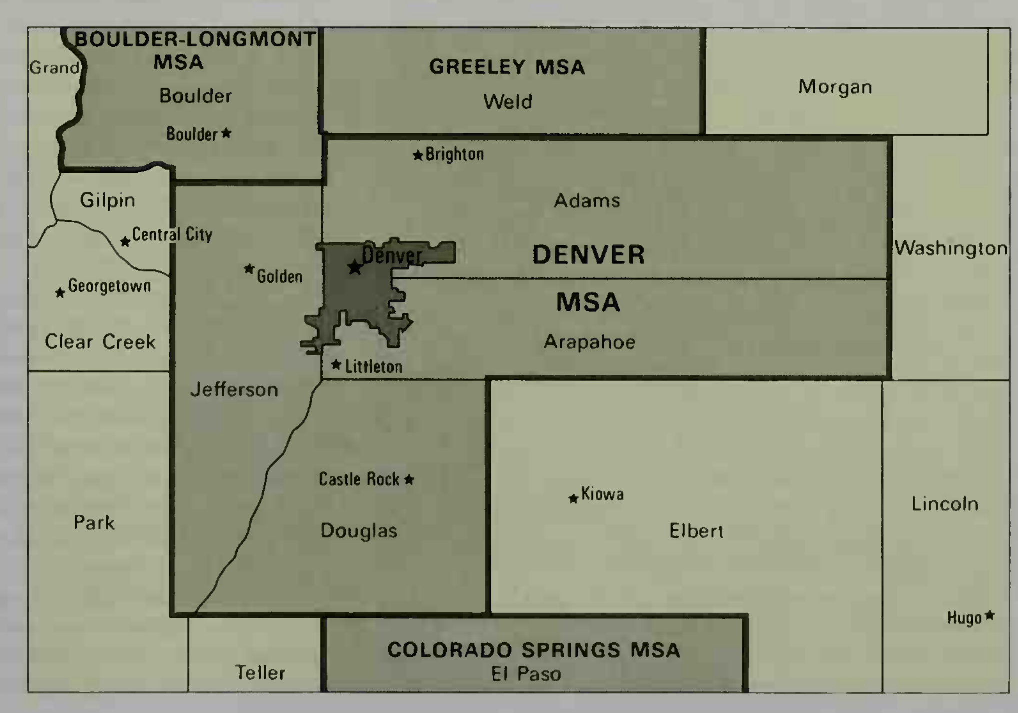
Metropolitan area plans

Various types of plans have been devised in attempts to solve the governmental and financial problems of metropolitan areas. These plans try to provide efficient government and a well-balanced economic policy for an entire metropolitan area. In most cases, however, local governments want to retain control over such important activities as education, police and fire protection, and zoning. This desire for local political independence has hampered efforts to develop effective plans. In many countries, the national government and the state or provincial governments handle most issues concerning growth and development of metropolitan areas.



The chief programs used in providing more efficient government and public financing for metropolitan areas include (1) annexation, (2) extramural jurisdiction, (3) county government, (4) special districts, (5) metropolitan federation, and (6) tax sharing.

Annexation. Most cities grew to their present size through annexation, which involves absorbing the outlying areas. Today, however, suburban residents generally oppose this method because they do not want to lose governmental independence.



Extramural jurisdiction. Some states and provinces give central cities governmental control of areas outside their boundaries. For example, Alabama cities have powers for $1\frac{1}{2}$ or 3 miles (2.4 or 4.8 kilometers) outside their city limits, depending on their population. Powers of extramural jurisdiction, also called *extraterritorial powers,* include police protection and sanitary regula-

The Denver Metropolitan Statistical Area (MSA) covers five Colorado counties. The map at the right also shows three other MSA's—Boulder-Longmont, Greeley, and Colorado Springs.

WORLD BOOK map

tion. They also may cover taxation of businesses and the control of subdivisions beyond city lines.

County government in some states and provinces provides urban services for areas outside city limits. For example, California has county governments that supply health and welfare assistance, police and fire protection, and other services to such areas.

A metropolitan county government provides urban services for an entire county, including central cities. Miami-Dade County, Florida, which includes Greater Miami, operates under a metropolitan county government plan. Voters from Miami and other cities and districts in the metropolitan area elect members of a governing commission. The commission carries out plans for providing many services and for development of the entire county. Municipalities handle only local affairs.

City-county government operates in a number of cities, including New York City, St. Louis, and San Francisco. It combines city and county functions but does not include suburban development.

Special districts, also called *municipal authorities,* consist of two or more local units in a metropolitan area. They provide one or more specific government services, such as sewage disposal and water distribution. The governing boards of special districts have the power to levy taxes and to spend public money. Many districts also use the revenue from services to pay for construction, maintenance, and operation of facilities.

Districts and authorities have led to increased governmental unity. But they have added to, rather than reduced, the number of governmental units in metropolitan areas. One of the largest and most successful municipal authorities is the Port Authority of New York and New Jersey. It handles port development and transportation within about 25 miles (40 kilometers) of New York City, in New York and New Jersey (see **Port Authority of New York and New Jersey**). The Metropolitan Water District of Southern California serves about 15 million people in 300 communities, including Los Angeles.

Metropolitan federation combines all the local governments of a metropolitan area into a unit called a *federated city,* or *consolidated city.* The local units retain their own identities and carry on certain functions that they are best suited to handle, such as education, zoning, and police protection. The federated city administers the remaining functions for the entire metropolitan area. It has the taxing power to finance such functions, plus the authority to establish and carry out policies.

The City of Indianapolis-Marion County merges the governments of Indianapolis and most of the other communities of Marion County, Indiana. This federation, sometimes called *Unigov,* has responsibility for land use, water supply, sewage disposal, and public welfare. Institutions and services maintained separately by each municipality include public schools, hospitals, libraries, and police and fire protection. See **Indianapolis.**

Tax sharing allows communities in a metropolitan area to share the costs and benefits of development. In a tax-sharing plan, part of the revenue a community gains from a new tax-producing development is distributed among other communities that are affected by the development. For example, the construction of a shopping center in one community may cause heavier traffic in neighboring communities. Tax sharing would help the neighboring communities pay for the increased costs of maintaining their roads.

Since the late 1970's, many metropolitan areas have considered adopting tax-sharing plans. In the United States, such a plan operates in the Minneapolis-St. Paul metropolitan area. Under this plan, the communities contribute tax revenues to the plan according to the amount of increase in the *assessed* (estimated) value of business properties.

Metropolitan Museum of Art in New York City is the largest art museum in the United States. It includes more than 2 million works of art. The city of New York owns the building, but the collections belong to a corporation that runs the museum under a charter granted in 1870. The museum offers concerts and lectures in a 700-seat auditorium. Its shops sell art books, posters, and reproductions of works of art from the collections.

The collections of ancient art include Egyptian prehistoric pottery, wall paintings, sculpture, and jewelry, and an original Egyptian tomb dated about 2450 B.C. Greek and Roman objects include vases and stone sculptures, bronzes, gems, jewelry, glass, and wall paintings. Etruscan art includes terra cotta work. Art from Mesopotamia, Persia, and Turkey is represented by sculptures, ivories, bronzes, and works in silver and gold.

The collections of Asian art include works from China, Japan, Korea, India, and Southeast Asia dating from 2000 B.C. to the present. They contain paintings, sculpture, ceramics, bronzes, jades, decorative arts, and textiles. The Chinese galleries include monumental Buddhist sculpture and a Chinese scholar's garden court. The collection of Islamic art is the largest in the world. An entire wing is devoted to the arts of Africa, the Pacific Islands, and the Americas.

The collections of European paintings date from the 1400's through the 1800's. The decorative arts collection dates from the Renaissance to the 1900's and includes entire rooms from the palaces and great houses of France, England, and Spain.

The American art collections contain paintings, prints, drawings, decorative arts, and architecture from the colonial period to the 1800's. The museum also has 24 period rooms dating from 1640 to a Frank Lloyd Wright living room built from 1912 to 1915.

Art of the 1900's includes paintings, sculpture, works on paper, and decorative arts. These items are displayed in 22 galleries.

The Uris Center is the center for the museum's educational activities. It offers a library, auditorium, and classrooms. The Costume Institute collection contains clothing from the 1600's to the present from Europe, Asia, Africa, and the Americas.

The Cloisters, located in Fort Tryon Park, is a branch of the museum devoted to medieval art. Its collections include paintings, tapestries, metalwork, sculpture, ivories, and stained glass. The Cloisters also features parts of monasteries and churches from France and Spain, and a lovely outdoor garden.

Metternich, *MEHT uhr nihk* (1773-1859), served as Austrian minister of foreign affairs from 1809 to 1848. He

was the leading European statesman during most of that period, often called the *Age of Metternich.* Metternich was a political conservative who used his power both to protect the Austrian Empire and to support monarchs elsewhere against popular unrest. He was given the additional title of chancellor in 1821.

Metternich tried to maintain a balance of power in Europe. He played a major role at conferences of European leaders, beginning with the Congress of Vienna (1814-1815). This conference determined the rulers and boundaries of Europe after the defeat of Napoleon I. Metternich encouraged European powers to suppress liberal and nationalist activity. He employed a network of spies to inform him of political threats. Uprisings in Europe during 1830 weakened Metternich's power somewhat. He used strict censorship in an attempt to prevent the spread of revolutionary ideas to Austria. In 1848, however, revolution broke out in France and quickly spread to Austria and the rest of Europe. The people of Vienna demanded Metternich's resignation. Metternich resigned in March 1848 and fled to England. Metternich returned to Austria in 1851, but he never held office again.

Metternich was born in Koblenz, in what is now western Germany. His full name was Klemens Wenzel Nepomuk Lothar von Metternich. He began his diplomatic career in 1801 as Austrian minister to Dresden. His marriage to Princess Eleanore Kaunitz, granddaughter of the Austrian chancellor, aided his rise to power. The Austrian emperor gave him the title Prince von Metternich in 1813. Peter N. Stearns

Meuse River, *myooz,* rises in the Langres Plateau of eastern France, and flows north past Verdun through the Ardennes highlands. The river then flows northeast through Belgium past Namur and Liège. North of Liège, the river enters the Netherlands. Here, it makes a sweeping curve northwest and empties into the North Sea south of Rotterdam. The Meuse River is 575 miles (925 kilometers) long. In Belgium and the Netherlands, it is called the Maas.

Several navigable canals join the Meuse River along its course. Near Toul, France, the Meuse connects with the Marne-Rhine Canal. At Liège, the river is linked with the Albert Canal, which goes to Antwerp. At Maastricht, the Meuse River meets the Juliana Canal. Hugh D. Clout

Mexicali, *MEHK sih KAL ee* or *MEH hee KAH lee* (pop. 764,902), is the capital and one of the largest cities of the Mexican state of Baja California Norte. Mexicali lies across the border from Calexico, Calif. (see **Mexico** [political map]). The names of both cities are combinations of the words *Mexico* and *California.*

Mexicali was founded in 1903. Today, the city is a center of tourism. Tourists enjoy Mexicali's bullfights, rodeos, dune-buggy races, handicraft exhibits, Mexican and Oriental restaurants, and exclusive shopping district. The city also has a historical museum and numerous examples of modern and old Spanish-style architecture. Julian C. Bridges

Mexican Americans. See Hispanic Americans.

Mexican bean beetle. See Bean beetle.

Mexican hairless is a dog that has no coat of hair. Its skin is bare, except for a little tuft of hair on its forehead and a slight fuzz along its tail. The skin is a spotted, pinkish color. A Mexican hairless weighs about 12 pounds (5 kilograms). It has a narrow head and a pointed nose. Its body is lightly built, with a rounded back and a long tail. The Mexican hairless probably originated in China in the 1300's. It was first imported into Mexico by sailors.

Mexican turnip. See Jicama.

Mexican War (1846-1848) was fought between the United States and Mexico over disagreements that had been accumulating for two decades. In the course of the war, United States forces invaded Mexico and occupied the capital, Mexico City. By the Treaty of Guadalupe Hidalgo, the United States acquired from Mexico the regions of California, Nevada, and Utah, most of Arizona and New Mexico, and parts of Colorado and Wyoming. But many historians believe the war was an unnecessary attack on a weaker nation.

Causes of the war

Background of the war. In 1835, Texas revolted against the Mexican government, which then controlled the region. Texans established the Republic of Texas in 1836, but Mexico refused to recognize Texas's independence. The Mexican government warned the United States that if Texas were admitted to the Union, Mexico would break off diplomatic relations with the United States. James K. Polk was elected U.S. president in 1844. He favored the expansion of U.S. territory and supported the annexation of Texas. Texas was made a state in 1845, and Mexico broke off relations with the United States. At this point, the dispute could have been settled by peaceful means. But the United States wanted additional Mexican territory, and other quarrels developed.

One of these disputes was the question of the boundary between Texas and Mexico. Texas claimed the Rio Grande as its southwestern border. Mexico said that Texas had never extended farther than the Nueces River. Also, the U.S. government claimed that Mexico owed U.S. citizens about $3 million to make up for lives and

WORLD BOOK map

Campaigns of the Mexican War took place chiefly in Mexico, California, and Texas. The war ended soon after United States troops led by Major General Winfield Scott won a series of major battles and occupied Mexico City.

property that had been lost in Mexico since Mexico's war for independence from Spain ended in 1821. By the 1840's, many Americans demanded that the United States collect these debts by force.

More important was a growing feeling in the United States that the country had a "manifest destiny" to expand westward into new lands (see **Manifest destiny**). The westward movement had brought Americans into Mexican territory, especially California. Mexico was too weak to control or populate its northern territories. Both American and Mexican inhabitants were discontented with Mexican rule. California seemed almost ready to declare itself independent.

Events leading up to the war. In the fall of 1845, President Polk sent John Slidell to Mexico as American minister. Slidell was to offer Mexico $25 million and cancel all claims for damages if Mexico would accept the Rio Grande boundary and sell New Mexico and California to the United States. If Mexico refused to sell the territories, Slidell was to offer to cancel the claims on condition that Mexico agreed to the Rio Grande boundary. While Slidell was in Mexico, a new Mexican president came to power. Both the old and new presidents were afraid their enemies would denounce them as cowards if they made concessions to the United States. They refused to see Slidell, who came home and told Polk that Mexico needed to be "chastised."

Meanwhile, Polk had ordered Major General Zachary Taylor, who was stationed with about 4,000 men on the Nueces River, to advance to the Rio Grande. Taylor reached the river in April 1846. On April 25, a party of Mexican soldiers surprised and defeated a small group of American cavalry just north of the Rio Grande.

Polk had wanted to ask Congress to declare war on Mexico. The news of the battle gave him the chance to say that Mexico had "invaded our territory and shed American blood on American soil." In reality, Mexico had as good a claim as the United States to the soil where the blood was shed. But on May 13, 1846, Congress declared war on Mexico.

The war

The Americans had two aims. They wanted to add to the United States the territory that Mexico had been asked to sell. They also wished to invade Mexico to force the Mexicans to accept the loss of the territory.

The Mexican Cession was the land Mexico *ceded* (gave up) to the United States in the Mexican War. The cession covered what are now California, Nevada, Utah, and parts of four other states.

The occupation of New Mexico and California. In June 1846, General Stephen W. Kearny set out with about 1,700 troops from Fort Leavenworth, Kans., to capture New Mexico. In August, the expedition entered the New Mexican town of Santa Fe and took control of New Mexico. The next month, Kearny pushed across the desert to California.

Meanwhile, in June 1846, a group of American settlers led by U.S. Army officer John C. Frémont revolted in California against the Mexican government. This rebellion became known as the Bear Flag Revolt because of the portrayal of a grizzly bear on the settlers' flag. In July, U.S. naval forces under Commodore John D. Sloat captured the California town of Monterey and occupied the San Francisco area. On December 6, Kearny led about 100 troops in the bloody Battle of San Pasqual near San Diego. Reinforcements from San Diego helped save the small American army. In January 1847, U.S. troops under Kearny and Commodore Robert F. Stockton of the Navy won the Battle of San Gabriel near Los Angeles. This victory completed the American conquest of California.

Taylor's campaign. Before war officially began, General Zachary Taylor had driven the Mexicans across the lower Rio Grande to Matamoros in the two battles of Palo Alto and Resaca de la Palma. These battles occurred on May 8 and 9, 1846. On May 18, Taylor crossed the river and occupied Matamoros. After waiting for new troops, he moved his army up the river and marched against the important city of Monterrey. Monterrey fell on September 24, after a hard-fought battle. Before the end of the year, Taylor had occupied Saltillo and Victoria, important towns of northeastern Mexico. However, Mexico still refused to negotiate with the United States.

Polk and his advisers decided to land an army at Veracruz, on the east coast, and strike a blow at Mexico City. Many of Taylor's best troops were ordered to join Major General Winfield Scott, who was placed in charge of the new campaign. President Antonio López de Santa Anna of Mexico commanded the Mexican Army. He learned of the American plans and immediately led a large army against Taylor at Buena Vista, in the mountains beyond Saltillo. Although the Mexican forces nearly overran the U.S. positions, Taylor's troops eventually defeated them. General Taylor became a hero because of his victories and was elected President of the United States in 1848.

Doniphan's victories. In December 1846, Colonel Alexander W. Doniphan led about 850 troops south from Santa Fe to capture the Mexican city of Chihuahua. The American troops defeated a Mexican army at El Brazito on Christmas Day. Doniphan's army won the furious Battle of the Sacramento, fought just outside Chihuahua on Feb. 28, 1847. The Americans occupied the city on March 1.

Scott's campaign. General Scott was at this time the officer of highest rank in the United States Army. With a force of about 10,000 men, he landed near Veracruz on March 9, 1847. Twenty days later he captured the city, and on April 8 he began his advance toward the Mexican capital. The American army stormed a mountain pass at Cerro Gordo on April 17 and 18 and pushed on. Near Mexico City, American troops fought and won the

battles of Contreras and Churubusco on August 19 and 20. The Mexican Army was superior in numbers but poorly equipped and poorly led.

After a two weeks' armistice, the Americans won a battle at Molino del Rey and stormed and captured the hilltop fortress of Chapultepec. On the following day, the Americans marched into Mexico City.

The peace treaty. Despite all the American victories, Mexico refused to negotiate a peace treaty. In April 1847, Polk had sent Nicholas P. Trist, chief clerk of the Department of State, to join Scott's army in Mexico and attempt to open diplomatic negotiations with Santa Anna. When the armistice of August failed, the president recalled Trist. But Santa Anna resigned shortly after Scott entered the Mexican capital. Mexico established a new government, and it feared that it might lose even more territory if it did not accept the American demands. At the request of the Mexican leaders and General Scott, Trist agreed to remain in Mexico against Polk's orders and negotiate a settlement.

The treaty was signed on Feb. 2, 1848, at the village of Guadalupe Hidalgo, near Mexico City. By this time, many people in the United States wanted to annex all of Mexico. But the treaty required Mexico to give up only the territory Polk had originally asked for. The United States paid Mexico $15 million for this territory, known as the Mexican Cession. In 1853, the Gadsden Purchase gave an additional 29,640 square miles (76,767 square kilometers) to the United States (see **Gadsden Purchase**).

Results of the war. The United States gained more than 525,000 square miles (1,360,000 square kilometers) of territory as a result of the Mexican War. But the war also revived the quarrels over slavery. Here was new territory. Was it to be slave or free? The Compromise of 1850 made California a free state and established the principle of "popular sovereignty." That meant letting the people of a territory decide whether it would be slave or free. However, popular sovereignty later led to bitter disagreement and became one of the underlying causes of the American Civil War. See **Compromise of 1850; Popular sovereignty.**

The Mexican War gave training to many officers who later fought in the Civil War. Civil War officers who also fought in the Mexican War included Ulysses S. Grant, William T. Sherman, George B. McClellan, George Gordon Meade, Robert E. Lee, Stonewall Jackson, and Jefferson Davis.

Bettmann Archive

The Battle of Palo Alto was one of the war's earliest battles. General Zachary Taylor's troops defeated the Mexicans near Brownsville, Texas, five days before the war officially began.

Principal battles

The chief battles of the Mexican War included:

Palo Alto, *PAL oh AL toh,* was one of the earliest battles of the war. General Taylor's troops defeated Mexican forces under General Mariano Arista on May 8, 1846, on a plain northeast of Brownsville, Texas.

Resaca de la Palma, *ray SAH kuh day lah PAHL muh.* A 2,300-man army under Taylor crushed 5,000 Mexican soldiers under Arista in Cameron County, near Brownsville, Texas, on May 9, 1846. General Taylor's two victories allowed him to cross the Rio Grande and to invade Mexico.

Buena Vista, *BWAY nah VEES tah.* Near the ranch of Buena Vista, Mexico, Taylor's force of about 5,000 men defended a narrow mountain pass against Santa Anna's army made up of from 16,000 to 20,000 men. Through this battle, fought on Feb. 22 and 23, 1847, the American forces established their hold on northeastern Mexico.

Cerro Gordo, *SEHR oh GAWR doh,* ranks among the most important battles the Americans fought on the march from Veracruz to Mexico City. A mountain pass near Jalapa, Cerro Gordo lies 60 miles (97 kilometers) northwest of Veracruz. General Scott's 9,000-man force attacked 13,000 Mexicans under Santa Anna and forced them to flee. The battle, fought on April 17 and 18, 1847, cleared the way to Mexico City.

Churubusco, *CHOO roo VOOS koh.* In the small village of Churubusco, 6 miles (10 kilometers) south of Mexico City, Scott's invading army won another major victory on Aug. 20, 1847. Scott's soldiers stormed the fortified camp of Contreras, then attacked the Mexican force at Churubusco. The Mexicans finally fled, and they sought refuge within the walls of the capital city. The Americans had about 9,000 men in the battle; the Mexicans, about 30,000.

Chapultepec, *chuh PUHL tuh PEHK,* was the last battle of the war before the capture of Mexico City. On Sept. 12, 1847, Scott's men attacked Chapultepec, a fortified hill guarding the city gates. The attacks continued the following day until the Mexicans retreated to Mexico City. On September 14, Scott's troops entered the Mexican capital. Joseph A. Stout, Jr.

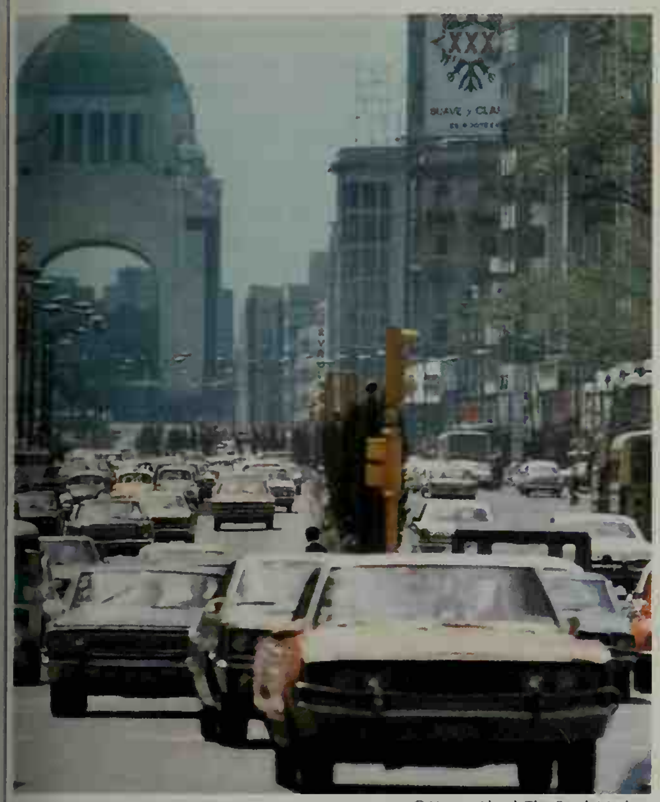
The rugged mountains of Mexico's Sierra Madre Occidental contain deep, steep-walled canyons carved by swiftly flowing streams. Some regions are so wild that they have not been explored on foot. The mountain range borders the western edge of Mexico's wide Central Plateau.

Mexico

Mexico is the northernmost country of Latin America. It lies just south of the United States. The Rio Grande forms about two-thirds of the boundary between Mexico and the United States. Among all the countries of the Western Hemisphere, only the United States and Brazil have more people than Mexico. Mexico City is the capital and largest city of Mexico. It also is one of the world's largest metropolitan areas in population.

To understand Mexico, it is necessary to view the nation's long early history. Hundreds of years ago, the Indians of Mexico built large cities, developed a calendar, invented a counting system, and used a form of writing. The last Indian empire in Mexico—that of the Aztec—fell to Spanish invaders in 1521. For the next 300 years, Mexico was a Spanish colony. The Spaniards took Mexico's riches, but they also introduced many changes in farming, government, industry, and religion. The descendants of the Spaniards became Mexico's ruling class. The Indians remained poor and uneducated.

During the Spanish colonial period, a third group of people developed in Mexico. These people, who had both Indian and white ancestors, became known as *mestizos.* Today, the great majority of Mexicans are mestizos, and they generally take great pride in their Indian ancestry. A number of government programs stress the Indian role in Mexican culture. In 1949, the government made an Indian the symbol of Mexican nationality. The Indian was Cuauhtémoc, the last Aztec emperor. Cuauhtémoc's bravery under torture by the Spanish made him a Mexican hero.



Few other countries have so wide a variety of landscapes and climates within such short distances of one another. Towering mountains and high, rolling plateaus cover more than two-thirds of Mexico. The climate, land formation, and plant life in these rugged highlands may vary greatly within a short distance. Mexico also has tropical forests, dry deserts, and fertile valleys.

Manufacturing, agriculture, mining, and tourism are all important to Mexico's economy. The country's leading manufactured products include automobiles, chemicals, processed foods, and steel. Crops are grown on only about an eighth of Mexico's land. The rest of the land is too dry, mountainous, or otherwise unsuitable for crops. However, Mexico is one of the world's leading producers of cacao beans, coffee, corn, oranges, and sugar cane.

Mexico is rich in minerals. It is the leading producer of silver in the world. The country also has large deposits of copper, gold, lead, salt, and sulfur. Mexico has produced oil since the early 1900's. But changes in the price of oil during the 1970's and the discovery of vast new deposits made Mexico a major exporter of petrole-

Ruins of an ancient Maya temple stand at Palenque in the state of Chiapas. The temple was built about A.D. 650, during a period when great Indian civilizations thrived in Mexico.

um products. Millions of tourists visit Mexico each year. The money they spend contributes to the nation's economy.

The Mexicans gained independence from Spain in 1821. A social revolution began in 1910, when the people of Mexico started a long struggle for social justice and economic progress. During this struggle, the government took over huge, privately owned farmlands and divided them among millions of landless farmers. The government established a national school system to promote education, and it has built many hospitals and housing projects.

Since the 1940's, the government has especially encouraged the development of manufacturing and petroleum production. But all these changes have not kept up with Mexico's rapid population growth, and the country faces increasingly difficult economic and social problems. A large number of the people still live in poverty.

Government

Mexico is a federal republic with an executive branch, a legislative branch, and a judicial branch or court system. The executive branch, headed by a president, is the decision-making center of the government. It establishes government policies, proposes laws, and controls the distribution of federal tax revenues.

Mexico has 31 states and 1 federal district. Each state has an elected governor and legislature. The Federal District is governed by the elected mayor of Mexico City. All Mexicans who are at least 18 years of age can vote.

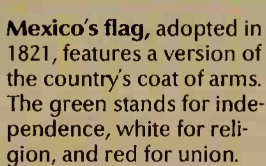
National government. Mexico's president has tremendous influence over the government. All prominent political figures in the executive branch depend indirectly on the president for their jobs. The president introduces many pieces of legislation. Many presidents also have used constitutional amendments to support government policies.

The president appoints a cabinet that directs government operations. Important cabinet members include the secretary of government and the secretary of finance and public credit. The president is elected by the people to a six-year term and may serve only one term of office. If the president does not finish the term, the legislature chooses a temporary president to serve until a special or regular presidential election is held.

Mexico's legislature is called the Congress. It consists of a Senate and a Chamber of Deputies. The Senate has 128 members who are elected to six-year terms. The Chamber of Deputies has 500 members. Three hundred of the deputies are elected from the country's electoral districts. The remaining 200 seats are filled by deputies who do not represent a particular electoral district. Members of the Chamber of Deputies serve three-year terms. Members of the General Congress can serve more than one term, but they may not serve consecutive terms.

Local government. State governors are elected by the people to six-year terms and state legislators to

Mexico in brief



General information

Capital: Mexico City.
Official language: Spanish. But about 7 percent of Mexicans use Náhuatl, Maya, Zapotec, or some other American Indian language.
Official name: Estados Unidos Mexicanos (United Mexican States).
National anthem: "Himno Nacional de México" ("National Anthem of Mexico").
Largest cities:
Mexico City (8,591,309)
Guadalajara (1,647,720)
Ecatepec (1,620,303)
Puebla (1,346,176)
Netzahualcóyotl (1,224,924)

Flag Research Center

Mexico's flag, adopted in 1821, features a version of the country's coat of arms. The green stands for independence, white for religion, and red for union.

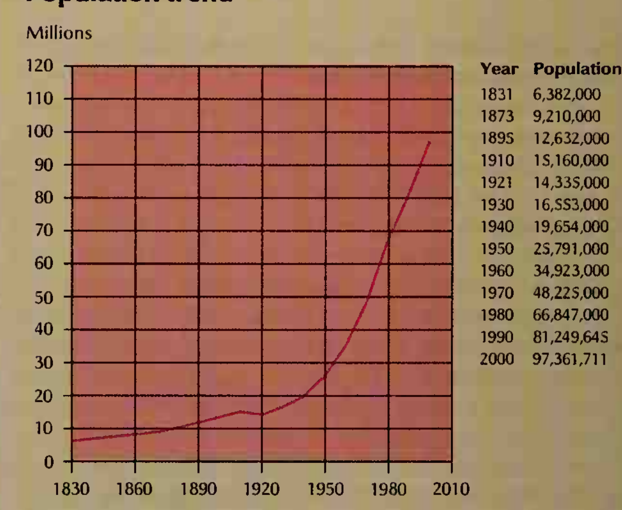
Coat of arms. A legend says the Aztec Indians built their capital Tenochtitlan (now Mexico City) where they saw an eagle perched on a cactus and devouring a snake.

Land and climate

Land: Mexico lies in North America. It is bordered by the United States on the north and by Guatemala and Belize on the southeast. The Gulf of Mexico and the Caribbean Sea lie to the east; the Pacific Ocean to the west and south. A chain of high volcanic mountains extends east-west across southern Mexico, just south of Mexico City. Lower mountain chains extend northwestward from each end of the volcanic chain, forming a great U-shape of mountains. Much of north-central Mexico is a high plateau rimmed by these mountain ranges. The Pacific Coast in the far south is rugged and has densely forested areas. The long peninsula of Baja California in the northwest is mostly desert with some mountains. The Yucatán Peninsula in the southeast is flat and forested. Mexico's chief rivers are the Rio Grande (at the U.S. border) and the Balsas.

WORLD BOOK map

Area: 756,066 mi² (1,958,201 km²). *Greatest distances*—north-south, 1,250 mi (2,012 km); east-west, 1,900 mi (3,060 km). *Coastline*—6,320 mi (10,170 km).
Elevation: *Highest*—Pico de Orizaba (also called Citlaltépetl), 18,410 ft (5,610 m). *Lowest*—near Mexicali, 33 ft (10 m) below sea level.
Climate: Northwest and north-central Mexico are mostly desert, with hot summers and cool to mild winters. The northeast coast has moderate rainfall with mild winters and warm summers. Central Mexico is dry, with temperatures varying according to altitude. High locations, such as Mexico City, have mild temperatures the year around. Low-altitude locations are warmer. Southern Mexico, including Yucatán, is warm and moist the year around.



Government

Form of government: Presidential democracy.
Chief executive: President (elected to 6-year term).
Legislature: Congress of two houses—128-member Senate and 500-member Chamber of Deputies.
Judiciary: Highest court is the Supreme Court of Justice.
Political subdivisions: 31 states, 1 federal district.

People

Population: *2002 estimate*—102,410,000. *2000 census*—97,361,711.
Population density: 135 per mi² (52 per km²).
Distribution: 75 percent urban, 25 percent rural.
Major ethnic/national groups: Almost entirely Mexican. Most Mexicans are of mixed American Indian and Spanish ancestry; some are entirely Indian or entirely of European descent; a few have partly black or East Asian ancestry.
Major religions: More than 85 percent Roman Catholic; some Protestants, Jews, and American Indian religions.

Population trend

Year	Population
1831	6,382,000
1873	9,210,000
1895	12,632,000
1910	15,160,000
1921	14,335,000
1930	16,553,000
1940	19,654,000
1950	25,791,000
1960	34,923,000
1970	48,225,000
1980	66,847,000
1990	81,249,645
2000	97,361,711

Economy

Chief products: *Agriculture*—corn, coffee, cotton, sugar cane, tomatoes, bananas, oranges, wheat, sorghum, barley, rice, beans, potatoes. *Manufacturing*—motor vehicles, processed foods, beverages, iron and steel, chemicals, electrical machinery. *Mining*—petroleum, natural gas, zinc, salt, silver, copper.
Money: *Basic unit*—new peso. One hundred centavos equal one peso.
Foreign trade: *Major exports*—petroleum, motor vehicles and engines, coffee. *Major imports*—industrial machinery, electric and electronic equipment, motor vehicles and parts. *Major trading partners*—United States, Japan, Canada, Germany.

three-year terms. The president can remove governors from office with the approval of the Senate. Each of Mexico's states is divided into *municipios* (townships). Each municipio has a president and a council elected to three-year terms.

Less than 10 percent of all tax revenues go directly to state and local agencies. State agencies depend on the national government, and local authorities on state agencies, for funds to carry out public works projects.

Politics. Mexico has a number of political parties. The most important include the *Partido Revolucionario Institucional* (Institutional Revolutionary Party), also known as the PRI; the *Partido de Acción Nacional* (National Action Party), or PAN; and the *Partido de la Revolución Democrática* (Party of the Democratic Revolution), or PRD.

The PRI, established in 1929 as the *Partido Nacional Revolucionario* (National Revolutionary Party), dominated Mexican politics and government for most of the 1900's. But in the 1980's, the party's power began to decline. In the 1990's, several Mexican states elected non-PRI candidates as governors. In 1997, the PRI lost its majority in the Chamber of Deputies for the first time. A non-PRI candidate was also elected to the powerful position of mayor of Mexico City. Then, in 2000, a non-PRI candidate was elected president of Mexico.

Courts. The highest court in Mexico is the Supreme Court of Justice. It has 21 members and several alternates, all of whom are appointed by the president. The Supreme Court selects members of a circuit and district court system. The highest court in each state is a Superior Court of Justice.

The courts rarely declare a law unconstitutional and generally support the president's policies. But Mexicans may use the courts to protect their individual rights through an *amparo* (protection) procedure. In amparo cases, the courts may decide that a law has resulted in unfair treatment and that an exception should be made, but the law in question is not changed. However, most Mexicans cannot afford to use the legal process.

Armed forces. About 175,000 men and women serve in Mexico's army, navy, and air force. The army is the largest branch of the Mexican armed forces. It has about 130,000 members. Mexican men are required to serve part-time for a year in the army after reaching the age of 18.

People

Population. Mexico's population is increasing rapidly, as a result of a traditionally high birth rate and a sharply reduced death rate. More than half of Mexico's population is under 20 years of age.

Since the early 1950's, improved living conditions and expanded health services have greatly reduced the death rate in the country. The relatively young population and its high rate of growth have placed tremendous pressure on such services as education, health care, and social security.

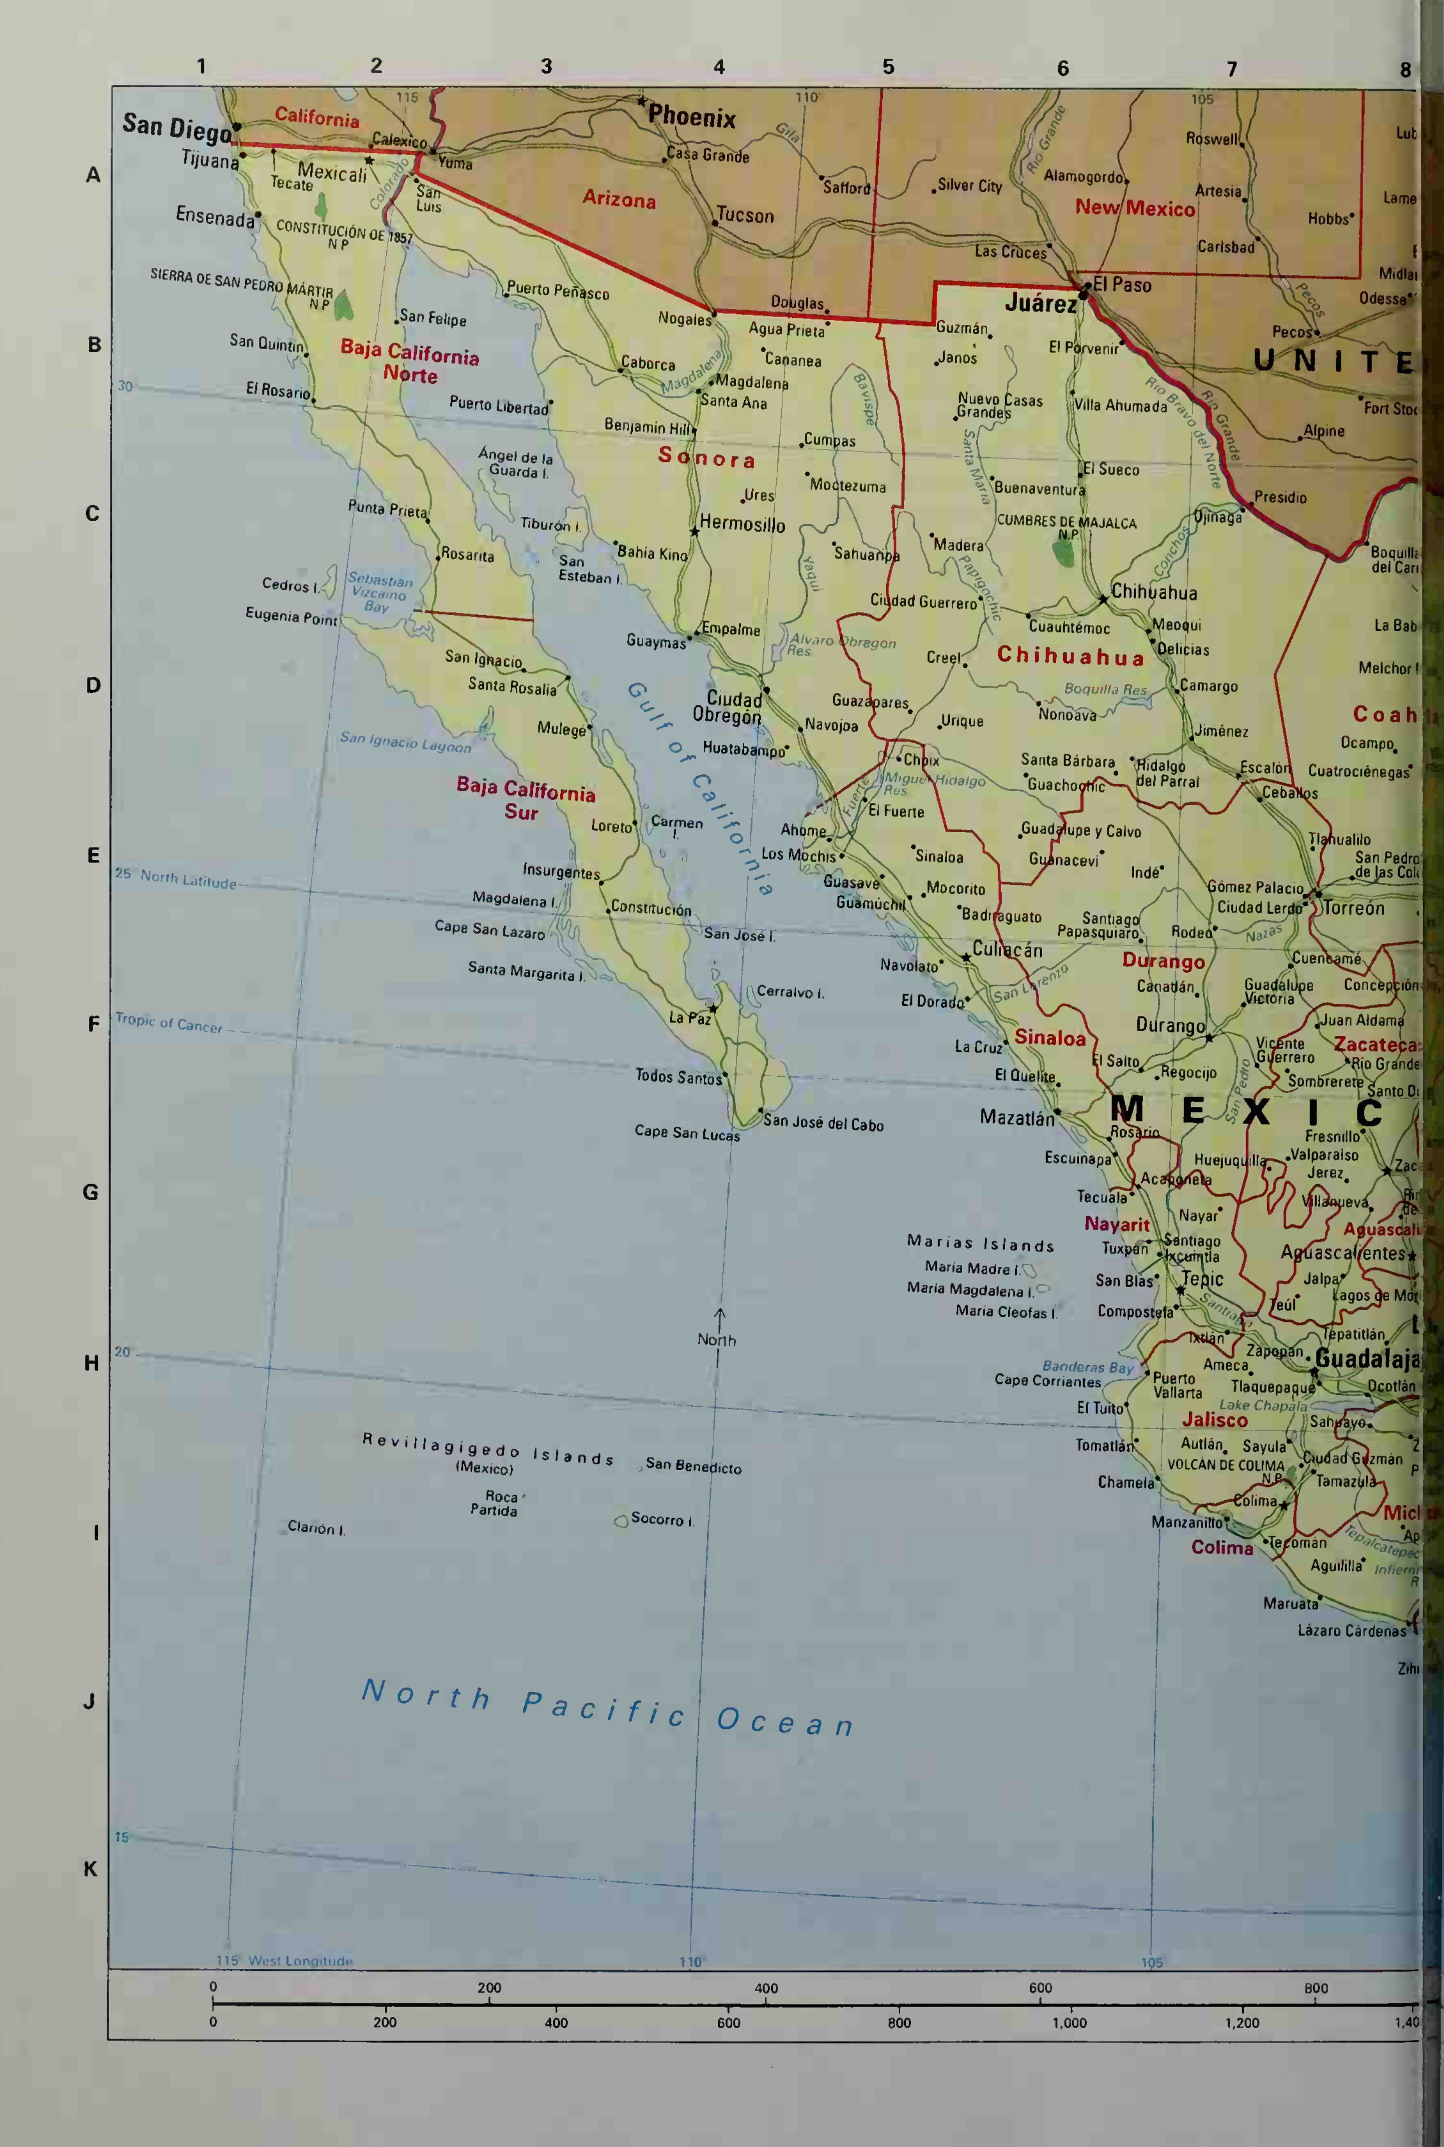
The strain on basic services is especially serious in urban centers. Many cities lack adequate housing, clean drinking water, and public transportation. Since 1970, the most rapid population growth has occurred in the states of México, Morelos, Campeche, and Quintana Roo.

The high rate of population growth has contributed to a shortage of jobs in Mexico. Since the 1980's, far more people have entered the labor force than have retired, while the economy has generally failed to create enough jobs. This situation has led to a high rate of unemployment. It has also stimulated increasing migration of Mexicans to the United States.

Ancestry. The great majority of the Mexican people are *mestizos* (people of mixed white and Indian ancestry). Their white ancestors were mostly Spaniards who came to what is now Mexico during and after the Spanish conquest of 1519-1521. Their Indian ancestors were living in the region when the Spaniards arrived. Blacks and some Asians are also part of the Mexican population. The nation has some Indians and whites of unmixed ancestry. But most Mexicans think of themselves as mestizos. Being a mestizo is generally a matter of national pride. Most of Mexico's political, business, intellectual, and military leaders are mestizos.

Being an Indian in Mexico does not depend chiefly on ancestry. It is mostly a matter of way of life and point of view. For example, Mexicans are considered Indians if they speak an Indian language, wear Indian clothes, and live in a village where the people call themselves Indians. This is true even if they are actually mestizo or white. In some regions, such as Oaxaca and Yucatán, Indian culture influences the lifestyle of the mestizo population.

Language. Almost all Mexicans speak Spanish, the official language of Mexico and nearly all other Latin American countries. Many words that are used in the United States came from Mexico. They include *canyon, corral, desperado, lariat, lasso, macho, patio, politico, rodeo,* and *stampede.*



Most Mexican Indians speak Spanish in addition to their own ancient language. However, more than 5 million Mexican Indians primarily use an Indian language in daily life. The major Indian languages include Maya, Mixtec, Náhuatl, Otomí, Tarascan, and Zapotec. See **Spanish language.**

Way of life

The way of life in Mexico includes many features from the nation's long Indian past and the Spanish colonial period. But Mexico changed rapidly during the 1900's. In many ways, life in its larger cities has become similar to that in the neighboring United States. Mexican villagers follow the older way of life more than the city people do. Even in the villages, however, government programs are doing much to modernize the people's lives. Schools, health clinics, roads, electric power and running water, and government-sponsored television are bringing people in small towns into the general life of Mexico.

Mexican households consist of an average of five or six people. In many homes, several generations of the same family live together. Many women in the cities have jobs, and the women who live in farm areas often help cultivate the fields. Mexican girls do not have as much individual freedom as do girls in the United States and Canada. Farm boys work in the fields, and many young people in the cities have part-time or full-time jobs.

City life. The most urban areas of Mexico include the

Federal District and the states of Nuevo León and Baja California Norte. Mexico City, which is the country's capital and largest city, has more than 8 ½ million people. The city's metropolitan area has a population of over 17 million. In addition, Mexico City is the chief city in one of the most populous urban centers in the world (see City [table: The 50 largest urban centers in the world]). Nine other cities in the country have more than 1 million people. These cities are, in order of size, Guadalajara, Ecatepec, Puebla, Netzahualcóyotl, Juárez, Tijuana, León, Monterrey, and Zapopan. Approximately 60 other cities in Mexico have populations that exceed 200,000.

Many Mexican cities and towns began as Indian communities. After the Spaniards arrived in the region, they built the main church and the chief public and government buildings around a *plaza* (public square). The plaza is still the center of city life in Mexico, even in large cities. In the evenings and on Sunday afternoons, the people gather in the plaza to talk with friends or to listen to music.

The city centers are filled with high-rise buildings, and modern houses and apartment buildings occupy the suburbs. But older parts of towns and cities have rows of homes built in the Spanish colonial style. Most of these houses are made of stone or *adobe* (sun-dried clay) brick. Small balconies extend from some windows. A Spanish-style house also has a *patio* (courtyard), which is the center of family life. This gardenlike area of the house may have a fountain, flowers, vines, and pots of blooming plants.

All of the large Mexican cities have grown very rapidly because people have moved there from the rural areas to find jobs and a better life. As a result, many cities suffer from serious social and environmental problems. Houses in many of the poor sections are made of scraps of wood, metal, and whatever other materials can be found. Most of them lack electric power and running water. The large number of cars and trucks cause frequent traffic jams. Air pollution is very bad in Mexico City, and it causes many people to suffer from respiratory and eye diseases.

Many people who move to cities have no regular jobs. Others do not earn enough to support themselves. Entire families must work—sometimes at two or three jobs—in order to survive. Many poor people with no skills find jobs as street vendors, construction workers, or street cleaners. Others make a living by washing clothes and cleaning houses. After they have lived in the city for a while, many of the poor find better-paying jobs in factories.

Rural life. About 1 out of every 4 Mexicans lives on a farm or in a small village. Most of these farmers live near their fields. The villages are very poor and have little access to such basic social services as health care and education. Most young people leave the villages to find work in the cities and towns.

Population density

The population of Mexico is concentrated in the south-central region of the country, particularly around Mexico City. The cities shown on the map are among the largest in Mexico.

WORLD BOOK map

The village homes stand along dusty streets that are simple dirt roads or are paved with cobblestones. In most of the villages, a Roman Catholic church stands on one side of the plaza, which forms the center of the community. On the other sides of most village plazas are a few stores and government buildings.

Almost every village, and every city and town, has a marketplace. Going to market is one of the chief activities of the people in farm areas. Men, women, and children take clothes, food, lace, pictures, toys, baskets, or whatever else they wish to sell or trade. They either rent stalls in which to display their goods, or spread the merchandise on the ground. The people spend one day each week at the marketplace chatting with friends and doing business. Farmers often trade their goods instead of selling them, and much bargaining takes place.

© Lee Foster, Bruce Coleman Inc.

Modern machinery is used by many Mexican farmers. The government promotes modern farming methods, but some farmers still use hand tools and follow ancient farming practices.

The shape and style of village houses vary according to the climate. People on the dry central plateau build homes of adobe, brick, cement blocks, or stone, with flat roofs of red tile, sheet metal, or straw. Some of these houses have only one room, a dirt floor, and few or no windows. The kitchen may be simply a lean-to built of poles and cornstalks placed against an outside wall. If a house does not have a lean-to kitchen, the family may build a cooking fire on the floor. The smoke from the fire curls out through the door and windows.

In areas of heavy rainfall, many houses have walls built of poles coated with lime and clay. This mixture lasts longer in the rain than adobe does. The houses have sloping roofs to allow the water to run off easily. Some Indians in southern Mexico build round houses. In Yucatán, most village houses are rectangular with rounded ends. The roofs are made of palm leaves.

Most Indians live in villages in central and southern Mexico and the Yucatán Peninsula and are poor. Dishonest outsiders have treated many Indians unfairly, sometimes taking their land, exploiting them for cheap labor, or charging them higher prices for goods and services. As a result, conflicts between Indians and wealthier neighbors have occurred.

Food and drink. Thousands of years ago, the Indians of what is now Mexico discovered how to grow corn. It became their most important food. Today, corn is still the chief food of most Mexicans, especially in rural areas. Mexican cooks generally soften the corn in hot limewater, boil it, and then grind it into meal.

The main corn-meal food is the *tortilla,* a thin flat bread shaped by hand or machine and cooked on an ungreased griddle. It also may be made with wheat flour. The tortilla is the bread of most Mexicans. It can be eaten plain or as part of (1) the *taco,* a folded tortilla filled with chopped meat, chicken, or cheese, and then fried; (2) the *enchilada,* a rolled-up tortilla with a similar

Extremes of poverty and wealth can be seen in Mexico City. Poor people live in shacks on the outskirts of the city, *top.* Wealthy Mexicans, by contrast, can afford luxury condominiums with tennis courts and swimming pools, *above.*

filling and covered with a hot sauce; or (3) the *tostada,* a tortilla fried in deep fat until it becomes crisp, and served flat with beans, cheese, lettuce, meat, and onions on top.

Many Mexicans eat *frijoles* (beans) that are boiled, mashed, and then fried and refried in lard. Poorer Mexicans may eat frijoles every day, often using a folded tortilla to spoon up the beans. Rice is also boiled and then fried. Other popular foods include *atole* (a thick, soupy corn-meal dish) and *tamales* (corn meal steamed in corn husks or banana leaves, and usually mixed with pork or chicken). Most Mexicans like their foods highly seasoned with hot chili pepper or other strong peppers. Turkey is a popular holiday dish. It is often served with *mole,* a sauce made of chocolate, chili, sesame seed, and spices.

The poorer families eat little meat because they cannot afford it. They may vary their basic diet of corn and beans with fruit, honey, onions, tomatoes, squash, or sweet potatoes. Favorite fruits include avocados, bananas, mangoes, oranges, and papayas. The fruit and leaves of the prickly pear, a type of cactus, are boiled, fried, or stewed. Wealthier Mexicans have a more balanced diet.

Popular beverages in Mexico include water flavored with a variety of fruit juices, and cinnamon-flavored hot chocolate cooked with water and beaten into foam. Mexicans also drink coffee, milk, soft drinks, and mineral water. Alcoholic beverages include *mescal, pulque,* and *tequila,* which are made from the juice of the maguey plant, and beer and wine.

Clothing. Mexicans in the cities and larger towns wear clothing similar to that worn in the United States and Canada. The village people wear simple types of clothing that vary according to region and climate. The designs of these clothes date back hundreds of years. In central and southern Mexico, men generally wear plain cotton shirts and trousers, and leather sandals called *huaraches.* Wide-brimmed felt or straw hats called *sombreros* protect Mexican men from the hot sun. During cold or rainy weather, they may wear *ponchos* (blankets that have a slit in the center for the head and are draped over the shoulders). At night, the men may wrap themselves in colorful *serapes,* which are blankets carried over one shoulder during the day. The village women wear blouses and long, full skirts, and usually go barefoot or wear plastic sandals. They cover their heads with fringed shawls called *rebozos.* A mother may wrap her baby to her back with a rebozo.

Some of the villagers' clothing is homemade. Hand weaving was an ancient Indian art, and today the Indians are famous for their beautiful home-woven fabrics. Styles of weaving vary throughout Mexico, and an Indian's region can be identified by the colors and designs of his poncho or serape. For example, blankets with a striped rainbow pattern come from the Saltillo area of the country.

Some Indians wear unusual clothing. Large capes made of straw are worn in Oaxaca state. On holidays, Indian women on the Isthmus of Tehuantepec wear a wide, lacy white headdress called a *huipil grande.* According to legend, this garment was copied from baby clothes that were washed ashore from a Spanish shipwreck. The Indian women thought the clothes were head shawls. In Yucatán, Maya women wear long, loose white dresses that are embroidered around the neck and bottom hem.

Mexicans sometimes wear national costumes on holidays and other special occasions. The men's national costumes include the dark blue *charro* suit, made of doeskin or velvet. It has a *bolero* (short jacket) and tight riding pants with gold or silver buttons down the sides. A flowing red bow tie, spurred boots, and a fancy white sombrero complete the costume.

Probably the best-known women's costume is the *china poblana.* It is usually worn in the *jarabe tapatío,* or Mexican hat dance. A legend says the china poblana was named for a Chinese princess of the 1600's who was kid-

Mexican clothing includes the traditional dress of various Indian groups as well as modern styles. The Huichol Indians embroider their clothes with detailed, colorful patterns, *left.* In cities and large towns, Mexicans wear pants, shirts, and other clothes similar to those worn in the United States and Canada, *right.*

napped by pirates and sold in the slave market. She was brought to Acapulco, where a kindly merchant of Puebla bought her. In Puebla, she dedicated her life to helping the poor. The princess adopted a costume that the local women later imitated. Today, it consists of a full red-and-green skirt decorated with beads and other ornaments, a colorfully embroidered short-sleeved blouse, and a brightly colored sash. See **Clothing** (picture: Traditional costumes).

Holidays. Mexicans celebrate their Independence Days, September 15 and 16, and other holidays with colorful *fiestas* (festivals). Every Mexican city, town, and village also holds a yearly fiesta to honor its local patron saint. Most fiestas begin before daylight with a shower of rockets, loud explosions of fireworks, and ringing of bells. During the fiestas, the people pray and burn candles to their saints in churches decorated with flowers and colored tissue paper. They dance, gamble, hold parades, and buy refreshments in the crowded marketplaces and public square. Fireworks are again set off at night.

In the smaller towns and villages, cockfights and amateur bullfights are also held during fiestas. In the larger towns and the cities, most fiestas include less religious worship than do the village fiestas. The people watch plays and professional bullfights, ride merry-go-rounds and Ferris wheels, and buy goods at merchants' booths.

Guadalupe Day is Mexico's most important religious holiday. It honors the Virgin of Guadalupe, the patron saint of Mexico. Guadalupe Day is celebrated on December 12, when the Virgin is believed to have appeared as an Indian maiden on Tepeyac Hill in Mexico City.

On the nine nights before Christmas, friends and neighbors gather and act out the journey of Mary and Joseph to Bethlehem. These nine ceremonies are called *posadas.* Each night after the posada, the children play the *piñata* game. Piñatas are containers made of earthenware or papier-mâché. Many piñatas are shaped like animals and are filled with candy, fruit, and toys. A piñata is hung above the heads of the children. Then the youngsters are blindfolded and take turns trying to break the piñata with a stick. After it breaks, the children scramble to collect the scattered presents. On Twelfth-night, 12 days after Christmas, parents fill their children's shoes with presents. See **Christmas** (picture: A Mexican tradition).

Recreation. Soccer is the most popular sport in Mexico, followed by baseball. Boys and men often can be found playing soccer or baseball on vacant lots, and many play on teams in amateur leagues. Mexico also has professional baseball and soccer leagues. Basketball has

Bullfighting is the most popular spectator sport in Mexico. Almost all large cities and many small towns have bullrings.

Worshipers wave palm branches in a church procession through the streets of Puebla on Palm Sunday. Religion plays an important role in the lives of most Mexicans. More than 85 percent of Mexico's people are Roman Catholics.

Melinda Berge, Bruce Coleman Inc.

become popular. Jai alai is also a popular sport.

Most Mexicans enjoy watching bullfights. Almost all large cities have bullrings. Mexico City has the largest bullring in the world. It seats about 55,000 people.

On Sundays—the only day most Mexicans do not work—many families go to the park to relax and picnic. Mexicans also enjoy watching movies and television, dancing at nightclubs or discos, and entertaining friends and relatives at home. Many wealthier Mexicans visit the country's historic sites and resorts along the coast.

Religion. More than 85 percent of Mexico's people belong to the Roman Catholic Church. Mexico also has some Protestants, Jews, and other religious groups.

Roman Catholic missionaries and priests first arrived from Spain in the early 1500's. They baptized millions of Indians. But the rain, sun, and other forces of nature remained an important part of religion to the Indians. Today, millions of Indian villagers still combine ancient religious practices with Catholicism.

During the Spanish colonial period, the Roman Catholic Church was closely linked with the government as the official state church. The church became wealthy and powerful, and prohibited other religions. Beginning in the mid-1800's, the Mexican government greatly reduced the political and economic power of the church by prohibiting churches from owning property and participating in politics. However, these laws were not always enforced. In 1991, Mexico's legislature passed constitutional amendments to end a number of these restrictions.

Education. Throughout the Spanish colonial period, the Roman Catholic Church controlled education in what is now Mexico. During the 1800's, the newly independent government and the church struggled for power, and the government won control of the schools. Mexico's present Constitution, adopted in 1917, prohibited religious groups and ministers from establishing schools or teaching in them. But the laws often were not enforced. Changes to the Constitution, passed in 1991, legalized church-owned schools and the teaching of religion in them. Before these changes were passed, about 95 percent of Mexico's schoolchildren attended public elementary schools. Only about 5 percent of schoolchildren attended private elementary schools.

During the early 1900's, less than 25 percent of Mexico's people could read or write. Since the Revolution of 1910, and especially since the early 1940's, the government has done much to promote free public education. It has built thousands of new schools and established teachers' colleges. The government spends large sums on education each year. Today most Mexican adults can read and write. For the country's literacy rate, see **Literacy** (table).

Mexican law requires all children from the age of 6 through 14 to go to school. After kindergarten, a child has six years of elementary school, followed by three years of *basic secondary* school. Graduates of basic secondary school may go on to a three-year *upper secondary* school. Many upper secondary schools are privately run, some by colleges in order to prepare students for college work. Other upper secondary schools offer business and technical courses.

About 85 percent of school-age children in Mexico attend school. About 80 percent complete elementary school, and approximately 40 percent finish some secondary school. Few go on to upper secondary schools or college.

Courses of higher education at Mexico's many universities, specialized colleges, and technical institutes last from three to seven years. The oldest and largest Mexican university is the National Autonomous University of Mexico in Mexico City. See **Mexico, National Autonomous University of.**

Arts

The arts have been an important part of Mexican life since the days of ancient Indians. The Maya and Toltec Indians built beautiful temples and painted *murals* (wall paintings) in them. The Aztec Indians composed music and poetry. The Spaniards brought a love for beautiful buildings and for literature. Indian craftworkers built and decorated thousands of churches based on Spanish designs. During the 1900's, Mexico produced many important architects, painters, composers, and writers.

Architecture of the ancient Indians was related chiefly to religion. The Indians built stone temples on flat-topped pyramids, and decorated them with murals and sculptured symbols. These symbols represented the feathered-serpent god Quetzalcóatl and the Indians' other gods. Many ancient structures still stand near Mexico City and at Chichén Itzá in Yucatán. See **Maya** (Arts and crafts); **Pyramids** (American pyramids).

After the Spanish conquest, the earliest mission churches were designed in a simple style. Later churches, especially those built during the 1700's, took on a more ornamental style. The huge Metropolitan Cathedral in Mexico City, begun in 1573 but not completed for hundreds of years, shows the influence of many different styles of architecture. During the 1900's, many Mexican architects combined ancient Indian designs with modern construction methods. Their work includes the beautiful buildings of the National Autonomous University of Mexico by Félix Candela and Carlos Lazo, and the striking National Museum of Anthropology in Mexico City by Pedro Ramírez Vázquez. Other examples include the apartment buildings called Jardines de Pedregal by Luís Barragán, and the 44-story Latin-American Tower in Mexico City.

Painting. During the Spanish colonial period, many artists painted murals in churches or portraits of government officials. But Mexican painting is best known for the artists who did their work after the Mexican Revolution of 1910. Beginning in the 1920's, José Orozco, Diego Rivera, and David Siqueiros painted the story of the revolution on the walls of public buildings. Important Mexican painters of later years include Rufino Tamayo and José Luis Cuevas. Since the 1960's, many Mexican painters have turned from revolutionary themes and have followed the latest art influences from other countries. See **Painting** (Modern Mexican painting).

The National Museum of Anthropology in Mexico City houses priceless displays of ancient Indian art. The building's interior was designed by architect Pedro Ramírez Vázquez.

Literature. Outstanding colonial writers included the dramatist Juan Ruiz de Alarcón and the poet Sor Juana Inés de la Cruz. In 1816, José Joaquín Fernández de Lizardi published *The Itching Parrot,* probably the first Latin American novel. After 1910, revolutionary themes became important in novels by such writers as Mariano Azuela and Martín Luis Guzmán. These themes sometimes appear in the works of later writers, such as Carlos Fuentes, Juan Rulfo, and Agustín Yáñez. Leading Mexican poets of the 1900's included Amado Nervo, Octavio Paz, Carlos Pellicer, Alfonso Reyes, and Marco Antonio Montes de Oca. See **Latin American literature.**

Music. Early Indians used drums, flutes, gourd rattles, and seashells as well as their voices for music and

The ornate religious architecture of the Spanish colonial period is represented by the Church of San Francisco Acatepec, built in 1730 near Puebla. Its main entrance and towers are decorated with brightly colored tiles that form striking patterns.

dances. This ancient music is still played in some parts of Mexico. Much church music was written in the colonial period. Folk songs called *corridos* have long been popular in Mexico. They may tell of the Mexican Revolution, a bandit or a sheriff, or the struggle between church and state. In the 1900's, Mexican composers, including Carlos Chávez and Silvestre Revueltas, used themes from corridos or ancient Indian music.

Today, strolling musical groups called *mariachis* perform along streets and in restaurants. Mariachi groups include singers, and players of guitars, trumpets, and violins. The music of *marimbas*—instruments similar to xylophones—is also popular. Folk dances are important features of Mexican fiestas. In the Mexican hat dance, also called the *jarabe tapatío,* dancers perform a lively sequence with hopping steps and heel-and-toe tapping.

The land

Mexico has six main land regions: (1) the Pacific Northwest, (2) the Plateau of Mexico, (3) the Gulf Coastal Plain, (4) the Southern Uplands, (5) the Chiapas Highlands, and (6) the Yucatán Peninsula. Within these six land regions are many smaller ones that differ greatly in altitude, climate, and land formation. Many kinds of plants and animals also live in Mexico.

The Pacific Northwest region of Mexico is generally dry. The Peninsula of Lower California, the region's westernmost section, consists largely of rolling or mountainous desert. During some years, the desert receives no rain at all. It has a few oases, where farmers in small settlements grow dates and grapes. The northwestern corner and southern end of the peninsula get enough rain for a little farming. The lowest point in Mexico is in the far northern area, near Mexicali. This area, 33 feet (10 meters) below sea level, is the southern end of the huge Imperial Valley of California.

The most valuable land of Mexico's Pacific Northwest lies along the mainland coastal strip. There, in fertile river valleys, is some of Mexico's richest farmland. The valleys are irrigated with the waters of the Colorado, Fuerte, Yaqui, and other rivers. Steep, narrow mountain ranges extend in a north-south direction in the state of Sonora, east of the coastal plain. The ranges lie parallel to each other and separate the upper river valleys. In these basins are cattle ranches, irrigated farmland, and copper and silver mines.

The Plateau of Mexico is the largest of Mexico's land regions. It has most of the Mexican people and the largest cities. The plateau is the most varied land region, and consists of five sections.

The Cordillera Neo-Volcánica (Neo-Volcanic Chain), a series of volcanoes, extends across Mexico at the plateau's southern edge. Many of the volcanoes are active. The volcanic soils are fertile and receive enough rain for agriculture. Corn, beans, and other crops have been grown on the slopes since the days of the ancient Indian civilizations. The highest point in Mexico is 18,410-foot (5,610-meter) Pico de Orizaba (Citlaltépetl). Southeast of Mexico City are the volcanoes Ixtacihuatl and Popocatépetl, both more than 17,000 feet (5,180 meters) high. To the west is Lake Chapala, Mexico's largest lake. It covers 417 square miles (1,080 square kilometers). See **Ixtacihuatl; Orizaba, Pico de; Popocatépetl**.

The Mesa Central (Central Plateau), which lies north of the Neo-Volcanic Chain on the plateau, is the heart of

Victor Englebert

The Mexican hat dance is a popular Mexican dance. It is often performed by the Ballet Folklórico, a dance company that appears regularly in the Palace of Fine Arts in Mexico City.

Mexico. It averages about 7,000 feet (2,100 meters) above sea level. The rainfall in this section is enough to raise corn or beans, and wheat and barley grow well there. The Aztec capital of Tenochtitlan stood at the southern edge, in the beautiful Valley of Mexico. Mexico City was built on the same site after the Spanish conquest, and became the capital during the colonial period. Today, it is also the country's leading center of culture, industry, and transportation. Several small lakes, including famous Lake Xochimilco, are in the Mexico City area (see **Lake Xochimilco**).

The western part of the Mesa Central is called the *bajio* (flat). This region covers one of the most productive agricultural areas in the country. The bajio also includes the manufacturing centers of Guadalajara, León, Querétaro, and San Luis Potosí.

The Mesa del Norte (Northern Plateau) makes up more than half the Plateau of Mexico. It extends from the Mesa Central north to the United States. The Mesa del Norte is highest in the south and west, with altitudes from 6,000 to 9,000 feet (1,800 to 2,700 meters). In the north and east, it is less than 4,000 feet (1,200 meters) high. Low mountains rise from 2,000 to 3,000 feet (610 to 910 meters) above its plains. This section receives little rainfall except in the higher mountains, where frost is a constant threat to farming. Only in such irrigated places as the Saltillo and Torreón areas is farming really successful.

Deserts cover large areas of the Pacific Northwest and Northern Plateau regions of Mexico. The deserts support a wide variety of plant life, including large cactuses.

The low mountains of the mesa have rich deposits of metal ores. The Spaniards began developing these mines during the 1500's. They also established huge ranches in the nearby dry hills and plains to supply the miners with beef, horses, and mules. In the Durango and Chihuahua areas, *vaqueros* (cowboys) developed skills at riding and at roping cattle. American cowboys later copied these skills.

The Sierra Madre Occidental is a long mountain range that forms the western rim of the Plateau of Mexico. For hundreds of years, this range was a natural barrier to transportation between the plateau and the west coast. Paved roads and a railroad were not built across it until the 1900's. The range includes some of Mexico's most rugged land. Short, steep streams flowing to the Pacific Ocean have cut canyons more than 1 mile (1.6 kilometers) deep through the mountains. The largest canyon is the spectacular Barranca del Cobre, cut by the Urique River. This deep, wide gorge is so wild that parts of it have not been explored on foot.

The Sierra Madre Oriental, the plateau's eastern rim, is actually a series of mountain ranges. In many places between the ranges, highways and railroads climb up to the plateau from the east coast. Monterrey, near large deposits of coal and iron ore, is the major center of the Mexican steel industry. See Sierra Madre.

© Keith Gunnar, Bruce Coleman Inc.

The Central Plateau has some of Mexico's richest farmland. The southern edge of the region includes sugar cane fields that stretch toward the foothills of the volcano Popocatépetl.

The Gulf Coastal Plain. North of Tampico, the plain is largely covered by tangled forests of low, thorny bushes and trees. This section of the plain is generally dry, and farming is possible only along rivers and with the aid of irrigation. South of Tampico, the rainfall increases. The plant life gradually changes southward, and becomes a tropical rain forest in Tabasco. The southern section has some rich farmland.

Many of Mexico's longest rivers flow into the Gulf of Mexico from the coastal plain. They include the Rio Grande, which forms about 1,300 miles (2,090 kilometers) of Mexico's border with the United States. Large petroleum deposits lie beneath the plain and offshore. Huge sulfur deposits occur near the Gulf of Mexico in the Isthmus of Tehuantepec. The isthmus, which is about 135 miles (220 kilometers) wide, is the narrowest part of Mexico. See Gulf of Mexico; Rio Grande.

The Southern Uplands consist largely of steep ridges and deep gorges cut by mountain streams. The region includes a large, hot, dry valley just south of the Neo-Volcanic Chain. This valley is drained by the Balsas River. The Sierra Madre del Sur, a rugged mountain range, rises southwest of the valley along the Pacific Ocean. The famous beach resort of Acapulco is on this coast. A little farming takes place on the steep mountainsides. The Oaxaca Plateau makes up the eastern part of the Southern Uplands. Monte Albán, an ancient Indian political center, was built there on a flattened mountaintop. Much of the gold of the Aztec empire probably came from the Oaxaca Plateau.

The Chiapas Highlands have great blocklike mountains that rise more than 9,000 feet (2,700 meters) above sea level. There are also many relatively flat surfaces at high altitudes. These tablelands are farmed by Indians who speak Maya and other ancient languages. Most of

Tropical rain forests are found in the southern areas of the Gulf Coastal Plain and on the Yucatán Peninsula. The crowns of the tall trees form a thick canopy that prevents most light from reaching the forest floor.

the region's modern farming development is taking place in deep, broad river valleys. With irrigation, farmers grow coffee, fruits, and other crops.

The Yucatán Peninsula is a low limestone plateau with no rivers. Limestone dissolves in water, and rainfall reaches the sea through underground channels dissolved out of the rock. Great pits have formed where the roofs of these channels have fallen in. The pits were the sacred wells of the ancient Maya Indians. The northwestern part of the region is dry bushland. There, leaves of agave plants provide a yellow fiber called *henequen,* which is used in making twine. To the south, the rainfall increases, and tropical rain forests cover the land. See **Yucatán Peninsula.**

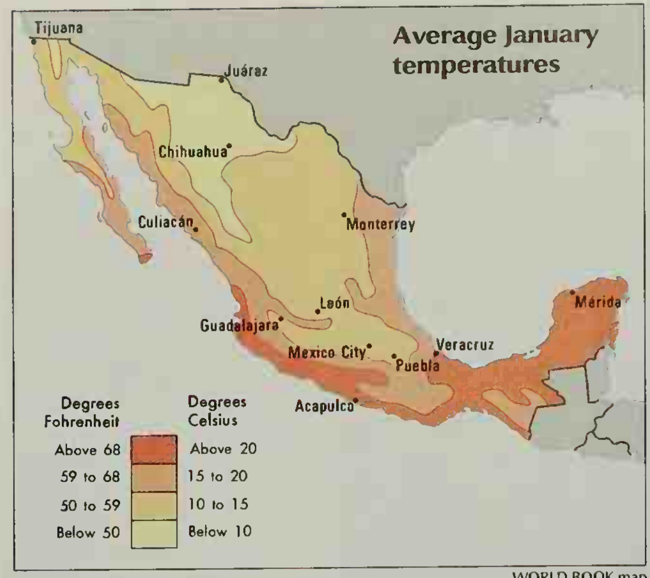
Plant and animal life. Forests cover about a fifth of Mexico. The northwestern and central mountains have forests that include ebony, mahogany, rosewood, walnut, and other valuable hardwoods used in making furniture. Large pine forests also grow in the mountains and supply timber for Mexico's pulp and paper industry. Sapodilla trees, which grow in southern Mexico, provide *chicle,* a gumlike substance used in making chewing gum.

Mexico also has a great variety of flowers and cactus plants. The country's thousands of kinds of flowers include azaleas, chrysanthemums, geraniums, orchids, and poinsettias. The northern deserts have hundreds of kinds of cactus plants.

Deer and mountain lions live in Mexico's mountains. The country's northern deserts have coyotes, lizards, prairie dogs, and rattlesnakes. Mexico also has some alligators, jaguars, opossums, and raccoons. Chihuahuas, the world's smallest dogs, originally came from Mexico.

Mexico has hundreds of kinds of birds, including the beautifully colored quetzals of the southern forests. Other birds include flamingoes, hummingbirds, herons, parrots, and pelicans.

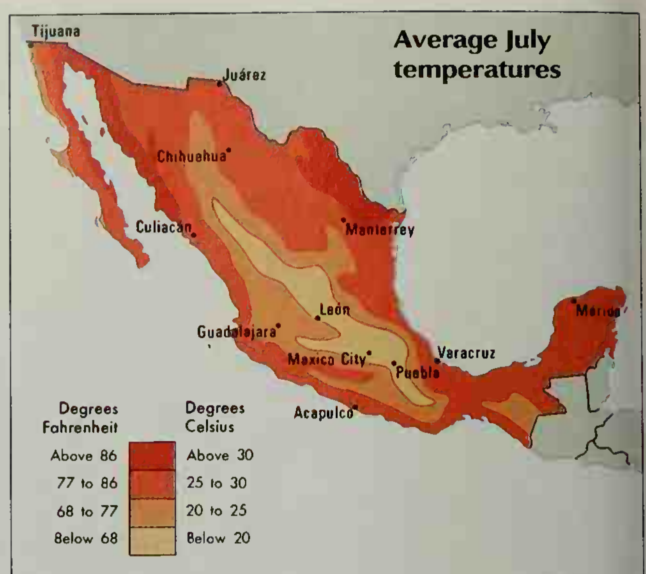
Fish and shellfish are plentiful in the coastal waters, lakes, and rivers. The freshwater fish of Mexico include bass, catfish, and trout. Along the Caribbean coast of the Yucatán Peninsula are coral reefs with many kinds of tropical fish. Marlin, swordfish, and tarpon are among the game fish caught in the seas off Mexico's coasts.



Climate

The climate of Mexico varies sharply from region to region. These differences are especially great in tropical Mexico, south of the Tropic of Cancer. In the south, the wide variety in altitude results in three main temperature zones. The *tierra caliente* (hot land) includes regions up to 3,000 feet (910 meters) above sea level. This zone has long, hot summers and mild winters with no frost.

The *tierra templada* (temperate land), from 3,000 to 6,000 feet (910 to 1,800 meters), has temperatures that generally stay between 80° and 50° F. (27° and 10° C). Most crops can be grown there. The *tierra fria* (cold land) lies above 6,000 feet (1,800 meters). Frost is rare in this zone up to 8,000 feet (2,400 meters), but it may occur at almost any time. The highest peaks in the tierra fria are always covered with snow.



In tropical regions of Mexico, most rain falls in summer, usually as short, heavy, afternoon showers. Toward the south, the rainy season begins earlier and lasts longer.

The northern half of Mexico is usually dry and consists largely of deserts and semideserts. The lack of rainfall has limited agricultural development in the north. Only the mountainous sections receive enough rainfall for growing good crops without irrigation. Most of northern Mexico's rainfall also occurs during the summer. But northwestern Lower California receives most of its rainfall during the winter. Above 2,000 feet (610 meters), summer days are hot and nights are cool. During

the winter, days are warm and nights are cold. The coastal lowlands are hot, except on the cool Pacific coast of Lower California.

Economy

Until the mid-1900's, the Mexican economy was based on agriculture and mining. Since the 1940's, the government has promoted the development of industry, and Mexico now produces many of the manufactured products its people use.

In the 1970's, Mexico became a major exporter of oil to the United States. Income from oil production, which is controlled by the government, spurred the development of manufacturing and service industries. During the mid- and late 1970's, the price of oil was high. Mexico used its expected income from oil production as collateral to borrow money for many construction projects. But in the early 1980's, the price of oil fell. Mexico found it difficult to repay its loans, and spending had to be severely cut. The economy declined, and many Mexicans lost their jobs. In the late 1980's and early 1990's, the economy improved because the government attracted foreign investment and controlled inflation. Since the mid-1990's, however, the Mexican economy has generally struggled.

Service industries are those economic activities that produce services, not goods. Service industries account for about two-thirds of the total value of goods and services produced in Mexico. Service industries also provide about half of Mexico's jobs. Schools, hospitals, stores, hotels, restaurants, and police and fire protection are included in this group. Banking, trade, transportation, and communication are also service industries.

Manufacturing has expanded rapidly in Mexico since the 1940's. This expansion has led to related developments throughout the entire economy. For example, the production of raw materials for new factories has in-

creased. Banking, marketing, and other services have expanded. Heavy government spending on construction has provided additional housing for the growing industrial centers. Power plants have been built for the new industries, as well as highways and railroads for carrying goods. Until the 1970's, manufactured goods were intended to supply Mexican needs, and the Mexican government protected its industries from outside competition. Since the 1980's, however, the government has encouraged growth to supply foreign markets and has reduced the protection it gives Mexico's own industries.

Mexico's industrialization has been financed chiefly by the nation's business community. However, the Mexican government and foreign investors have also contributed much.

Mexico City is the leading industrial center. The city and its suburbs manufacture about half of the country's products. Monterrey and Guadalajara are also important manufacturing centers in Mexico. Government programs encourage the spread of industry to other areas. New factories have opened in Chihuahua, Juárez, Mexicali, Puebla, Tijuana, Toluca, Veracruz, and near the oil fields.

Many of the new factories along Mexico's border with the United States manufacture products for export to U.S. companies. These factories, called *maquiladoras,* have become an important part of Mexican industrial growth. They manufacture automobile engines and transmissions and assemble a variety of electrical goods, including stereo systems, computers, televisions, and kitchen appliances.

Mexico's leading products include chemicals, electrical machinery, iron and steel, motor vehicles, processed foods, and processed petroleum. Iron and steel are produced in the Monterrey area and at Lázaro Cárdenas. Other important products made in Mexico include beer, cement, clothing, fertilizers, household appliances, rubber, and wood pulp and paper.

Mexico has long been famous for the skill of its craftworkers. These craftworkers follow beautiful old Indian or Spanish-colonial designs. Their products generally vary by area. The articles made by these craftworkers include silver jewelry from Taxco, glassware and pottery from Guadalajara and Puebla, and hand-woven baskets and blankets from Oaxaca and Toluca. Many of the products are sold to tourists.

Agriculture. The various farming regions of Mexico differ greatly in altitude, rainfall, and temperature. As a result, many kinds of crops can be grown. However, most of the country is mountainous or receives little rainfall, and is naturally unsuited for agriculture. Crops are grown on only 12 percent of the total land area.

The best farmlands are in the southern part of Mexico's plateau. Rich soils, enough rainfall, and a mild climate there permit intensive cultivation. The northern part of the plateau has little rainfall and is used mainly for cattle grazing. Irrigation projects have developed some rich croplands. Fertile soils are found in the rainy, hot regions of the south and east and in the eastern coastal plains. But much work must be done to turn them into productive farmlands. This work includes clearing and draining the land, and controlling floods, insects, and plant diseases. The western coast of Mexico has fertile soils. But much of it is mountainous and dry.

Mexico's variety of climates enables the country to produce a wide range of crops. More land is used for corn, the people's basic food, than for any other crop. Other major crops include bananas, beans, coffee, cotton, oranges, potatoes, sorghum, sugar cane, and wheat. Mexican farmers also raise avocados, chili peppers, coconuts, grapes, lemons, mangoes, pineapples, safflower seeds, and tomatoes. Many tropical fruits and winter vegetables are exported to the United States. Vanilla and *cacao,* the plant from which chocolate is made, are raised in tropical wet areas of Mexico.

Livestock is raised throughout Mexico. Beef cattle

Mexico's gross domestic product

Mexico's gross domestic product (GDP) was $208,958,000,000 in 1996. The GDP is the total value of goods and services produced within a country in a year. *Services* include community, government, and personal services; finance, insurance, and real estate; trade, hotels, and restaurants; transportation and communication; and utilities. *Industry* includes construction, manufacturing, and mining. *Agriculture* includes farming, forestry, and fishing.

Production and workers by economic activities

Economic activities	Percent of GDP produced	Employed workers: Number of people	Employed workers: Percent of total
Community, government, & personal services	21	8,683,000	25
Trade, hotels, and restaurants	21	7,720,000	22
Manufacturing	21	5,779,000	16
Finance, insurance, real estate, & business services	14	1,361,000	4
Transportation & communication	10	1,449,000	4
Agriculture, forestry, & fishing	6	7,922,000	23
Construction	4	1,797,000	5
Mining	2	133,000	*
Utilities	1	202,000	1
Total	100	35,046,000	100

*Less than one-half of 1 percent.

Sources: International Labour Office; International Monetary Fund

graze in the dry northern pasturelands. Dairy cattle are raised chiefly in central Mexico. Farmers throughout Mexico also raise chickens, goats, hogs, horses, sheep, and turkeys.

Until the 1900's, most Mexicans made a living by farming land near their villages or working on large estates called *haciendas* for wealthy landowners. The Mexican Constitution of 1917 provided for land reform. By 1964, the government had broken up most of the haciendas and distributed the land to the peasants.

The Constitution also recognized the old system of *ejidos* (farmlands held in common by communities). On the ejidos, farmers either work on individual sections by themselves, or they work the land as a group and share in the crops. Today most ejidos are worked in individual sections. Ejidos include about half of Mexico's total cropland. The remainder is divided between small family farms and large haciendas that the Mexican government has not broken up.

Today agriculture provides about a fourth of all jobs but accounts for less than 10 percent of the total value of goods and services. The Mexican government tries to increase production by promoting modern farming methods by means of educational programs, financial aid, and public works projects, including dams for irrigation. But most small family farmers and those living on ejidos have not benefited from these programs. As a result, Mexico has some highly modern and productive commercial farms owned by a few people, who are prosperous. But the vast majority of Mexican rural dwellers live in poverty.

© Timothy Eagan, Woodfin Camp, Inc.
Beautiful silver objects, including vases, tableware, and jewelry, line the shelves of this shop in San Miguel de Allende. Mexico is the world's leading producer of silver.

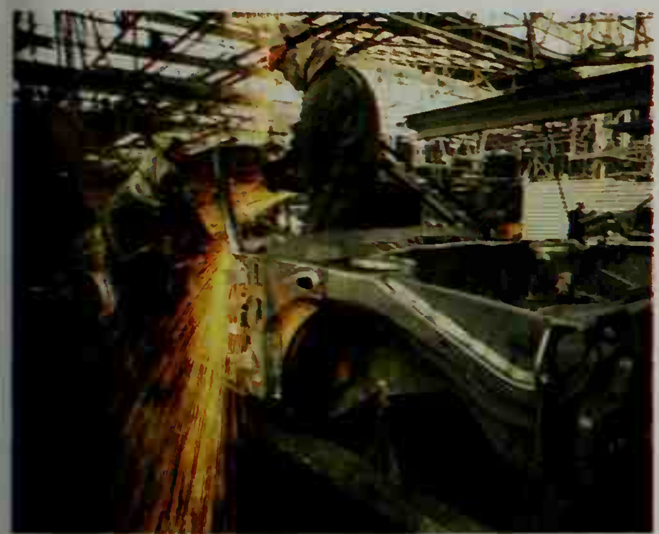
Mining. A wide variety of valuable minerals are mined in Mexico. The country ranks as the world's leading silver producer, mining about a sixth of the world's annual production. Most silver mines operate in the central regions of the country.

Mexico is a leading producer of petroleum. It pumps more than 950 million barrels of petroleum each year. Oil wells are found chiefly in the states of Campeche, Tabasco, and Veracruz, along the coast and in the Gulf of Mexico. The petroleum industry is operated by a government agency. In addition, Mexico produces much natural gas.

Mexico also mines large quantities of copper, gold, lead, salt, sulfur, and zinc. Other valuable minerals include antimony, bismuth, fluorite, manganese, and mercury. Large iron ore deposits support the nation's growing steel industry.

Fishing industry. Although Mexico has an extensive coastline, fishing accounts for less than 1 percent of the national income. Important ports include the cities of Ensenada and La Paz on the Baja California Peninsula, Guaymas in the state of Sonora, and Mazatlán in the state of Sinaloa. Fishing crews catch anchovies, oysters, sardines, shrimp, and tuna, much of it for export.

Energy sources. Wood is the main source of energy for poor people. Petroleum deposits provide cheap fuel oil and natural gas for industrial use. More than 80 percent of the energy used by industry and business comes from petroleum, and about 15 percent comes from natural gas. Petroleum and natural gas also generate about 70 percent of Mexico's electric power. Most of the rest



Oil refineries in Mexico process large amounts of petroleum. Oil is the country's most valuable natural resource. Petroleum and petroleum products account for more than a third of Mexico's earnings from foreign trade.

© Albano Guatti, The Stock Market

is produced by hydroelectric plants. Chicoasen Dam, Mexico's largest hydroelectric plant and one of the world's highest dams, is located on the Grijalva River in the state of Chiapas. The government handles almost all power production and distribution.

Trade. Mexico's leading exports include petroleum and petroleum products. The main industrial exports are automobile parts. Mexico also exports coffee, fruits and vegetables, and shrimp. Mineral exports include copper, salt, sulfur, silver, and zinc. The leading imports include industrial machinery, electric and electronic equipment, and motor vehicles.

About two-thirds of Mexico's trade is with the United States, but trade with Western European countries and Japan is increasing. Trade with other Latin American countries is relatively unimportant. But Mexico is trying to increase it through the Latin American Integration Association, an economic union of Mexico and 10 other Latin American nations. Mexico also belongs to a regional trading bloc that includes Canada and the United States. This bloc was created by the North American Free Trade Agreement (NAFTA), which calls for the reduction of tariffs and other trade barriers.

© Sergio Dorantes

Automobile production is an important manufacturing activity in Mexico. Many of the country's factories produce automobiles or automobile parts for export to the United States.

Tourism. Along with exports of manufactured goods and petroleum, tourism serves as one of Mexico's largest sources of income from abroad. Each year, millions of tourists—mostly Americans—visit Mexico. The tourist industry is also a major source of employment for the Mexican population. Tourists visit Mexico City, the old Spanish colonial cities of central Mexico, and the ruins of Mayan Indian cities on the Yucatán Peninsula. Beautiful beach resorts attract many people from the United States and Canada, especially in winter. Popular resort areas include Acapulco, Ensenada, Manzanillo, Mazatlán, Puerto Vallarta, and Zihuatanejo on the Pacific coast, and Cancún and Cozumel Island on the Caribbean coast.

Transportation in Mexico ranges from modern methods to ancient ones. Airlines, highways, and railroads connect all the major cities and towns. But some farmers still carry goods to market on their heads and backs, or by burros and oxcarts.

Mexico has a good highway system. The country has an average of about 1 automobile for every 12 people. Many buses connect Mexico's urban areas.

Mexico City is an important center of international air travel. Guadalajara, Acapulco, Monterrey, and Mérida also have large international airports. Mexico has an extensive government-owned railway network.

Mexico has more than 30 seaports. The major ones include Coatzacoalcos, Tampico, and Veracruz on the Gulf of Mexico, and Guaymas and Salina Cruz on the Pacific Ocean. The nation has a small merchant fleet.

Communication. The first book known to be published in the Western Hemisphere was a catechism printed in Mexico City in 1539. Today, books and magazines published in Mexico City are read widely throughout Mexico and all of Latin America. Mexico has more than 300 daily newspapers, representing many different political opinions. The largest newspapers include *Esto, Excélsior, El Heraldo de México, El Nacional, Novedades, Ovaciones, La Prensa,* and *El Universal,* all published in Mexico City. Other important newspapers include *La Jornada, Reforma,* and *Unomásuno.*

Mexico has an average of about 1 radio for every 4

people and 1 television set for every 6 people. Telephone and telegraph lines connect all parts of the country. The motion-picture industry of Mexico produces more films each year than that of any other Latin American nation.

History

Ancient times. The first people who lived in what is now Mexico arrived before 8000 B.C. They were Indians of unknown tribes who migrated from the north. These Indians were hunters who lived in small, temporary communities. They followed the herds of buffalo, mammoths, mastodons, and other large animals that roamed the land. About 7500 B.C., the climate became drier. The herds could not find enough grass to eat and died off. The Indians then lived on small wild animals or the berries and seeds of wild plants.

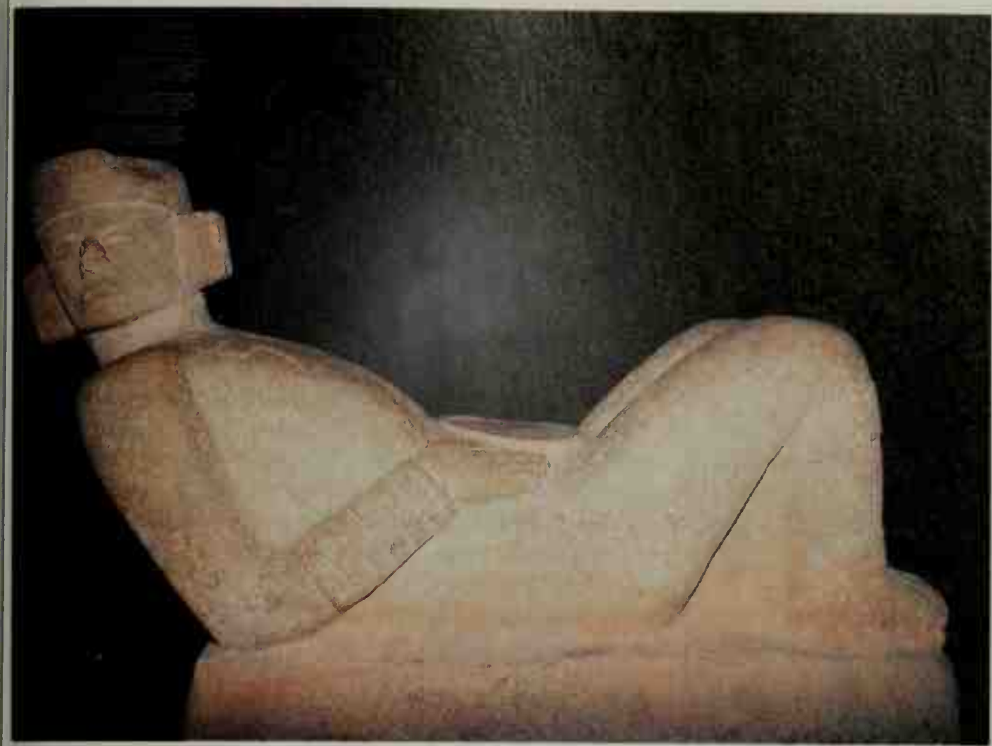
About 7000 B.C., Indians in what is now the Puebla region discovered how to grow plants for food and became farmers. They grew corn, which became their most important food, and avocados, beans, peppers, squashes, and tomatoes. These Indians were among the first people to cultivate these vegetables. They also raised dogs and turkeys for food. As the wandering bands of hunters became groups of farmers, they established permanent settlements.

The growth of villages. By 2000 B.C., large farm villages stood along Lake Texcoco in the fertile south-central Valley of Mexico, and in the southern highlands and forests. The farmers used irrigation to improve their crops. The villages grew, and new classes of people developed, including pottery makers, priests, and weavers. Trade in polished stones, pottery, and seashells was carried on with distant communities.

By 1000 B.C., the villagers were building flat-topped pyramids with temples on them. Some villages, including Cuicuilco near what is now Mexico City, became religious centers. Indians came from other communities to worship in the temples. Because these people were farmers, they worshiped gods that represented such natural forces as the rain and the sun. The villages grew into towns, from the Valley of Mexico to the Gulf of Mexico and to the Pacific Ocean, and south to what is now Guatemala.

The Olmec Indians of the southern Gulf Coast made the first great advance toward civilization in the Mexico region. Between about 1200 B.C. and 400 B.C., the Olmec developed a counting system and calendar. They also carved beautiful stone statues. See **Olmec Indians**.

The Classic Period. Great Indian civilizations thrived between A.D. 250 and 900, the Classic Period of Mexico. Huge pyramids dedicated to the sun and the moon were built at Teotihuacán, near what is now Mexico City. In the religious centers of southern Mexico and northern Central America, the Maya Indians built beautiful homes, pyramids, and temples of limestone. They recorded important dates on tall, carved blocks of stone and wrote in a kind of picture writing. In what is now the state of Oaxaca, the Zapotec Indians flattened a mountaintop and built their capital, called Monte Albán. See **Maya; Zapotec Indians**.



The reasons for the fall of these classic civilizations are not clear. The climate probably became even drier about A.D. 900, and not enough crops could be produced to feed the large population. Perhaps the city people attacked their neighbors to get more land. Or farmers may have revolted against the priests who had ruled them. In the north, wild Chichimec tribes destroyed a large number of cities.

The Toltec and the Aztec. Many wars took place after the Classic Period. The Toltec Indians established an empire during the 900's, with a major city at Tula, north of present-day Mexico City. Toltec influence spread throughout the central and southern regions. This influence included the use of stone pillars to support roofs, the worship of the feathered-serpent god Quetzalcóatl, and human sacrifice in religion. Invading Chichimec tribes destroyed the Toltec empire about 1200. See **Toltec Indians**.

The Aztec built the last and greatest Indian empire during the mid-1400's. The Aztec empire extended between the Pacific and Gulf coasts, and from the Isthmus

Important dates in Mexico

c. 2000 B.C. Village life developed in the Valley of Mexico.
c. A.D. 250-900 Great Indian civilizations thrived during the Classic Period.
c. 900-1200 The Toltec empire controlled the Valley of Mexico.
c. 1325-1350 The Aztec founded Tenochtitlan (now Mexico City).
1519-1521 Hernando Cortés conquered the Aztec empire for Spain.
1810 Miguel Hidalgo y Costilla began the Mexican struggle for independence.
1821 Mexico won independence.
1836 Texas won independence from Mexico.
1846-1848 The United States defeated Mexico in the Mexican War and won much Mexican territory.
1855 A liberal government under Benito Juárez began a period of reform.
1863 French troops occupied Mexico City.
1864 Maximilian of Austria became emperor of Mexico.
1867 Liberal forces led by Benito Juárez regained power.
1876-1880 and **1884-1911** Porfirio Díaz ruled Mexico as dictator.
1910-1911 Francisco I. Madero overthrew Díaz.
1917 A revolutionary constitution was adopted.
1929 The National Revolutionary Party (now called Institutional Revolutionary Party) was formed.
1934 The government began a major program of land distribution to farmers.
1938 Mexico took over foreign oil company properties.
1953 Women received the right to vote in all elections.
1968 Government troops put down student demonstrations in Mexico City.
1970's Major new petroleum deposits were discovered on the Gulf of Mexico coast.
1985 Two earthquakes struck south-central Mexico, killing about 10,000 people.
1994 NAFTA (North American Free Trade Agreement) took effect, providing for the gradual elimination of trade barriers among Mexico, the United States, and Canada.
1997 The Institutional Revolutionary Party lost its majority in the Chamber of Deputies for the first time.
2000 Vicente Fox Quesada of the National Action Party was elected president. He became the first non-PRI candidate elected to that office in 71 years.

A sculpture of the god Chac-mool, *shown here,* served as an altar during Maya religious ceremonies. Religious offerings were placed on the dish carved on the figure's stomach.

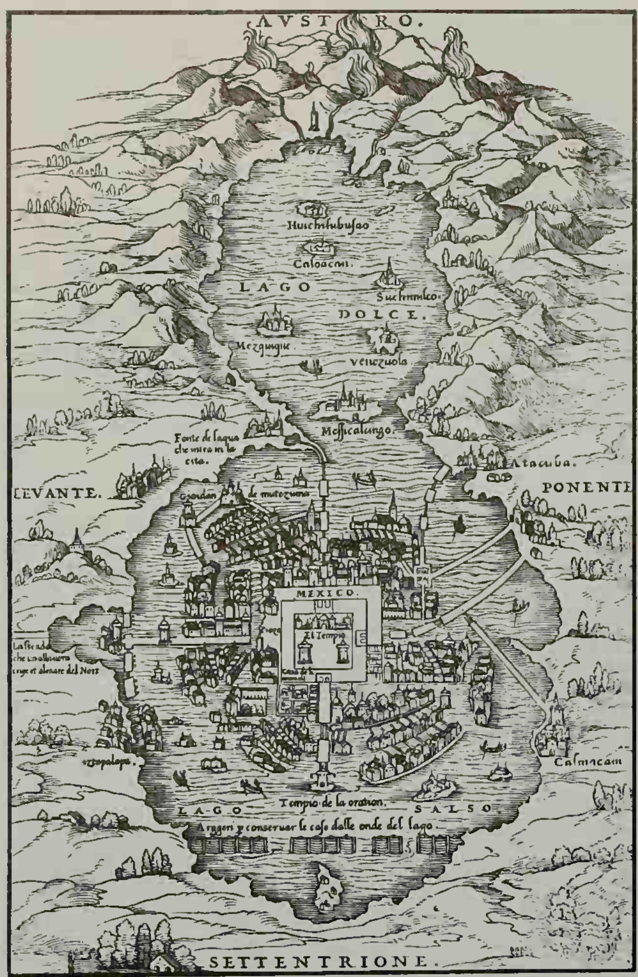
of Tehuantepec north to the Pánuco River. The Aztec capital, Tenochtitlan, stood on an island in Lake Texcoco at the site of Mexico City. According to Aztec tradition, Tenochtitlan was founded in 1325. But modern scholars believe it was founded somewhat later. When the Spaniards arrived in 1519, the city and its suburbs had a population of about 300,000.

The Aztec were fierce warriors who believed it their duty to sacrifice the men they captured in battle to their gods. Every year they sacrificed thousands of prisoners of war. The Aztec also composed beautiful music and poetry, and were skilled in medicine. They grew rich with gold, silver, and other treasures paid yearly by the cities and tribes they conquered. See **Aztec.**

The Spanish conquest. The Spaniards began to occupy the West Indies during the 1490's, and discovered Mexico in 1517. That year, Diego Velázquez, the governor of Cuba, sent ships under Francisco Fernández de Córdoba to explore to the west and search for treasure. Córdoba found the Yucatán Peninsula and brought back reports of large cities. Velázquez sent Juan de Grijalva in 1518. Grijalva explored the Mexican coast from Yucatán to what is now Veracruz.

Reports of the strangers were carried to the Aztec emperor Montezuma II, or Moctezuma II, in Tenochtitlan. The tales of Spanish guns and horses—which the Indians had never seen before—and of soldiers in armor made him fear that the Spaniards were gods.

A third expedition of about 650 Spaniards sailed from Cuba under Hernando Cortés, or Hernán Cortés, in February 1519. Cortés's 11 ships followed Grijalva's route along the coast. Cortés defeated large Indian armies with his horses and cannons. He founded Veracruz, the first Spanish settlement in what is now Mexico.



Montezuma sent messengers with rich gifts for Cortés, but he also ordered the Spaniards to leave. Instead, Cortés marched toward Tenochtitlan. He was joined by thousands of the Aztec's Indian enemies, who looked on him as the destroyer of the cruel Aztec. Montezuma did not oppose the Spaniards, possibly because he thought that Cortés might be a god. He allowed the invaders to enter Tenochtitlan in November 1519. The Spaniards were far too few to control Tenochtitlan by themselves. Cortés soon seized Montezuma and held him as hostage for the safety of the Spaniards.

In June 1520, the Aztec revolted. After a week of bitter fighting, the Spaniards tried to sneak out of the city. The Aztec discovered them, and hundreds of Spaniards were killed during *la noche triste* (the sad night). The rest, including Cortés, were saved because their Indian friends fought and stopped the Aztec. Six months later,

WORLD BOOK map

The Aztec empire reached the height of its power during the early 1500's, covering much of what is now south-central Mexico. In 1521, Spaniards led by the explorer Hernando Cortés conquered the Aztec and destroyed their civilization.

From a book by Giovanni Battista Ramusio. Library of Congress

The Aztec capital, Tenochtitlan (now Mexico City), stood on an island in Lake Texcoco. Raised roads connected it with the mainland. This map, published in 1556, is based on one believed to have been drawn by Hernando Cortés, conqueror of the Aztec.

Cortés returned to Tenochtitlan with Spanish forces and a large army of Indians. By May 1521, he had surrounded the Aztec capital with his army and boats, and had cut off the city's food and water. Battles, sickness, and starvation weakened the Aztec army. In August, Cuauhtémoc, the last emperor, surrendered the city. Cortés sent soldiers to take over the rest of the Aztec empire. Some Indians resisted, but most accepted Spanish rule without a fight. See **Cortés, Hernando.**

Spanish rule. After the fighting ended, the Spaniards faced the problem of how to govern the large number of people in the colony. To keep the Indians from revolting, King Charles I of Spain allowed them to speak their own languages and to be governed by their own officials. But he also made a few changes. The Indians had to pay a special tax called a *tribute* and to work for the Spaniards when help was needed. In addition, the Indians were required to convert to Roman Catholicism.

Tenochtitlan and other Indian cities became Spanish cities in which the whites ruled. The whites included *peninsulares* (people born in Spain) and *creoles* (Europeans born in the New World). *Mestizos* (people of mixed white and Indian ancestry) performed labor in the cities. The creoles and mestizos considered themselves superior to the Indians.

During the 1540's, the Spaniards discovered silver mines in the northern part of the colony. The silver brought much wealth to the creoles and peninsulares, and the silver mines drew additional Spanish immigrants. The creoles established estates called *haciendas*. There, they produced food and clothing for the new mining communities. The creoles used the power of the royal government to make the Indians work for them. The Indians lived on the haciendas when they had work. The rest of the time, they lived in their own villages.

The Indians were poor, but there was little they could do to change their situation. They were allowed to live separately according to their customs. As a result, the houses they lived in, the food they ate, and the way they worked changed little over the nearly 300 years of Spanish rule. The king agreed that Spanish laws gave the Indians the right to keep the lands they had owned before the conquest. The Indians found ways to blend the Roman Catholic faith with their own culture, and they respected their Spanish priests.

The Indians considered the king of Spain as their defender. The creoles were at first content to be ruled by Spain because the king was far away and he usually permitted them to govern themselves. The laws were made in Spain, but only a few Spanish officials worked in the colony. The officials could not enforce the laws if the creoles objected. However, in the late 1700's, King Charles III tried to reorganize the government, giving more power to himself and less to the creoles. He also raised taxes. Few creoles sought independence, but many wanted more control of their affairs.

Revolt against the Spaniards. In 1807, French forces occupied Spain and imprisoned King Ferdinand VII. Confusion spread in the colony. Some creoles plotted to seize the colony's government. One of these men was Miguel Hidalgo y Costilla, a priest. Late on the night of Sept. 15, 1810, he called Indians and mestizos to his church in the town of Dolores. He made a speech known as the *Grito de Dolores* (Cry of Dolores), in which he called for a rebellion so that Mexicans could govern

Fresco (1949) by Jose Clemente Orozco in the State Capitol, Guadalajara (© Robert Frerck)

Miguel Hidalgo y Costilla set off Mexico's struggle for independence in 1810. Mexico won freedom from Spain in 1821.

Mexico. Today, late on September 15, Mexico's president rings a bell and repeats the Grito de Dolores. Mexicans celebrate September 16 as Independence Day.

Hidalgo's untrained followers armed themselves and attacked Spanish officials and those who supported the Spaniards. At first, Hidalgo gained support for his cause. But most of his followers were Indians and mestizos, and not creoles. Some Indian communities also refused to support Hidalgo because of the violent ways of the rebels. Hidalgo was forced to retreat. In 1811, Spanish troops captured and executed him.

José María Morelos y Pavón, another priest, continued Hidalgo's struggle. In 1813, Morelos held a Congress that issued the first formal call for independence. The Congress wrote a constitution for a Mexican republic. Morelos hoped to attract the creoles who wanted reform. He succeeded further than Hidalgo. In 1815, however, Morelos too was captured and executed by the Spaniards.

By 1816, Spanish troops had captured or killed almost all of the rebels. Mexico was again at peace, and King Ferdinand VII had returned to the Spanish throne. But the king did not realize that most creoles supported him, and that they still only wanted reform. Instead, the king thought that all Mexicans were traitors to Spain. Ferdinand taxed the creoles and organized a large army to put down any revolutionary movement. His actions convinced many creoles that they no longer could trust Spain.

Independence. In 1820, a revolt by liberals swept Spain. Ferdinand's power weakened, and many creoles saw their chance for revolution. A group of powerful creoles supported Agustín de Iturbide, a military officer. Iturbide had been given command of a Spanish army to crush the last rebel leader, Vicente Guerrero. Instead of fighting Guerrero, Iturbide met with him peacefully. In February 1821, the two leaders agreed to make Mexico independent. They joined their armies and won the support of the liberal and conservative creoles. Only a small part of the Spanish forces in Mexico remained loyal to Spain. By the end of 1821, the last Spanish officials withdrew from Mexico, and Mexico became independent.

Following independence, the creoles could not agree on a form of government. Conservatives wanted a monarchy, but liberals called for a republic. The conservatives, who formed the majority, sought a monarch. They could not persuade a member of the royal family of Spain to be king, and so Iturbide became Emperor Agustín I in 1822. But Iturbide was a poor ruler, and most groups turned against him. In 1823, a military revolt drove him from power.

Mexico's Congress then followed the wishes of the liberals and began to write a constitution for a federal republic. But the creoles still disagreed on how the constitution should be written. Conservatives wanted a strong central government and wanted Roman Catholicism to be the national religion, as it had been under Spanish rule. Liberals wanted the central government to have less power and the states more, and they called for freedom of religion. The groups finally reached a compromise, though many conservative creoles did not support it. In 1824, Mexico became a republic with a president and a two-house Congress heading the national government, and governors and legislatures heading

The Republic of Mexico was established in 1824. It covered much of what is now the Western and Southwestern United States. In the mid-1800's, Mexico lost vast territories to the United States and sold the United States additional lands.

the states. Guadalupe Victoria, a follower of Hidalgo and Morelos, became the first president.

War with Texas and the United States. The mid-1800's was a time of great troubles in Mexico. Many creoles still did not support the Constitution, and Mexicans had little experience in lawmaking and self-government. Military men frequently revolted. One of them, General Antonio López de Santa Anna, became the most important political figure in the country. He was president 11 times between 1833 and 1855. The people elected him president in 1833, and he favored the liberal policies of the government that was temporarily heading the country. But he did not serve right away. In 1834, he joined the conservatives in a revolt against the temporary government, took control, and became a dictator.

Texas was then part of Mexico, but many people from the United States had settled there. When Santa Anna changed the Constitution to give himself more control over the provinces, Americans and Mexicans who supported the liberals in Texas revolted. In 1836, Santa Anna defeated a Texas force in the Battle of the Alamo at San Antonio. But later that year, Texas forces defeated his army at San Jacinto and captured him. Santa Anna signed a treaty recognizing the independence of Texas. In addition to what is now the state of Texas, the new republic of Texas included parts of present-day Colorado, Kansas, New Mexico, Oklahoma, and Wyoming.

The Mexican government did not recognize Santa Anna's treaty. Texas joined the United States in 1845, but Mexico still claimed it. Border disputes developed between Mexico and the United States. In April 1846, U.S. soldiers entered the disputed area and were attacked by Mexican soldiers. In May, the United States declared war on Mexico.

U.S. soldiers occupied what was then Mexican territory in Arizona, California, and New Mexico. In February 1847, U.S. General Zachary Taylor fought Santa Anna—who was again president—in Mexico, at the Battle of Buena Vista near Saltillo. Both sides claimed victory.

Taylor became a national hero in the United States and was elected president the next year. Other U.S. forces landed at Veracruz under General Winfield Scott. In September 1847, Scott captured Mexico City after the bitter Battle of Chapultepec. Six military students are said to have thrown themselves from Chapultepec Castle to their deaths during this battle, rather than surrender. Today, the Monument to the Boy Heroes stands in Chapultepec Park in their honor.

The Treaty of Guadalupe Hidalgo, signed in February 1848, ended the Mexican War. Under the treaty, Mexico gave the United States the land that is now California, Nevada, and Utah; most of Arizona; and parts of Colorado, New Mexico, and Wyoming. Mexico also recognized Texas, down to the Rio Grande, as part of the United States. Mexico received $15 million from the United States. In the Gadsden Purchase of 1853, the United States paid Mexico $10 million for land in what is now southern Arizona and New Mexico.

For fuller accounts of this period, see the articles on **Alamo; Gadsden Purchase; Guadalupe Hidalgo, Treaty of; Mexican War; San Jacinto, Battle of; Santa Anna, Antonio; Texas** (The Texas revolution).

Reform. The Mexican War exhausted the country's economy, and great political confusion developed. Santa Anna again seized power in 1853 and ruled as a dictator. But the liberals had been gaining strength since the war. In 1855, they drove Santa Anna from power.

Benito Juárez, a Zapotec Indian, and other men gave the liberal movement effective leadership. The liberals promoted the private ownership of land. After they took over in 1855, they passed laws to break up the large estates of the Roman Catholic Church and the lands of Indian villages. In 1857, a new Constitution brought back the federal system of government.

The new reforms resulted in a conservative revolt in 1858. Juárez fled from Mexico City. The liberals declared him president, and he set up a government in Veracruz. During the civil war that followed—the War of the Reform—a conservative government operated in Mexico City. The Catholic bishops supported the conservatives because of the liberals' opposition to the church. In 1859, Juárez issued his Reform Laws in an attempt to end the church's political power in Mexico. The laws ordered the separation of church and state, and the takeover of all church property. The liberal armies defeated the conservatives late in 1860, and Juárez returned to Mexico City in 1861.

The French invasion. The Mexican government had little money after the War of the Reform. Juárez stopped payments on the country's debts to Britain, France, and Spain. Troops of the three nations occupied Veracruz in 1862. The British and Spaniards soon left after they saw that the French were more interested in political power than in collecting debts. The French emperor, Napoleon III, took this opportunity to invade and conquer Mexico. French troops occupied Mexico City in 1863. Juárez escaped from the capital.

In 1864, Mexican conservatives, aided by Napoleon III, named Maximilian emperor of Mexico. Maximilian was a brother of the emperor of Austria. Juárez and the liberals fought guerrilla-style battles against Maximilian and the French invaders. In 1866, the United States put pressure on France to remove its troops. This pressure and the fighting against the liberals were problems for the French. Also, Napoleon III feared war would break out in Europe. In 1866 and 1867, he withdrew his forces from Mexico. Juárez's forces then captured and shot Maximilian. The conservative movement broke up. Juárez returned to Mexico City, and the country was united behind the liberals. Juárez served as president from 1867 until his death in 1872.

The dictatorship of Porfirio Díaz. Frequent revolts took place again after Juárez's death. In 1876, Porfirio Díaz, a mestizo general, overthrew Juárez's successor. Díaz developed good relations with the conservatives and with some liberal state leaders who cooperated with him. He used his army to control people who opposed him. Díaz served as president from 1876 to 1880, and from 1884 to 1911. The strength of his friends and the fear of his army helped him rule as a dictator. Many people who sided with him became wealthy.

Mexico's economy improved under Díaz. Railroads were built, mines and oil wells developed, and manufacturing industry expanded. But industrial wages were kept low, and attempts to form labor unions were crushed. Indian communities lost their land to big landowners. The great majority of Mexicans remained in poverty and ignorance. The benefits of Mexico's improved economy went chiefly to the big landowners, businessmen, and foreign investors.

The Revolution of 1910. Opposition to Díaz's rule began to grow after 1900. Francisco I. Madero, a liberal landowner, decided to run against him in 1910. During the campaign, Madero became widely popular. Díaz had him jailed until after the election, which Díaz won. Madero then fled to the United States.

In November 1910, Madero issued a call for revolution. He had opposed violence, but he saw no other way to overthrow Díaz. Revolutionary bands developed throughout Mexico. They defeated federal troops, destroyed railroads, and attacked towns and estates. In May 1911, members of Díaz's government agreed to force him from office, in hope of preventing further bloodshed. Díaz resigned and left Mexico, and Madero was elected president later that year.

Madero meant well, but he could not handle the many groups that opposed him. Some wanted a dictatorship again. Others called for greater reforms than Madero put through. In 1913, General Victoriano Huerta seized power, and Madero was murdered.

Some Mexicans supported Huerta's dictatorship, hoping for peace. But Madero's followers united behind Venustiano Carranza, a state governor, and the bitter fighting continued. President Woodrow Wilson of the United States openly sided with Carranza's revolutionaries. In 1914, U.S. forces seized Veracruz. Wilson hoped to prevent the shipment of arms from the seaport to Huerta's army. Later in 1914, Carranza's forces occupied Mexico City, and Huerta was forced to leave the country. See **Wilson, Woodrow** (Crisis in Mexico).

The Constitution of 1917. The victorious revolutionary leaders soon began to struggle among themselves for power. Carranza's armies fought those of Francisco ""Pancho" Villa and Emiliano Zapata. Villa and Zapata demanded more extreme reforms than Carranza planned. In 1915, the United States supported Carranza and halted the export of guns to his enemies. In revenge,

UPI/Bettmann

Rebel forces commanded by Emiliano Zapata marched toward Mexico City after the overthrow of Mexican dictator Victoriano Huerta in 1914. Zapata and Francisco "Pancho" Villa struggled for power against revolutionary leader Venustiano Carranza. But by 1916, Carranza controlled most of Mexico.

Villa crossed the border in 1916 and raided Columbus, N. Mex. His men killed 18 Americans. About five times as many Mexicans also died in the raid. President Wilson sent General John J. Pershing into Mexico, but Pershing's troops failed to capture Villa.

In 1916, Carranza's power was recognized throughout most of Mexico. He called a convention to prepare a new Constitution. The Constitution, adopted in 1917, combined Carranza's liberal policies with more extreme reforms. It gave the government control over education, farm and oil properties, and the Roman Catholic Church. It also limited Mexico's president to one term and recognized labor unions.

Carranza did little to carry out the new constitutional program. In 1920, he was killed during a revolt led by General Álvaro Obregón, who later became president.

Economic and social changes. Obregón distributed some land among the peasants, built many schools throughout the countryside, and supported a strong labor union movement. Plutarco Elías Calles, who had fought Huerta and Villa, became president in 1924. Calles carried on the revolutionary program. He encouraged land reform and enforced constitutional controls over the Roman Catholic Church. The bishops protested by closing the churches from 1926 to 1929. The closing of the churches resulted in a rebellion among the peasants. Emilio Portes Gil became president in 1928, but Calles remained the real power behind the presidency. In 1929, Portes Gil reached an agreement with church officials that allowed the Catholic Church to operate schools and churches without interference. In return, church leaders promised to stay out of political affairs.

Calles formed the National Revolutionary Party in 1929. Until then, Mexican political parties had been temporary groups organized by presidential candidates. The National Revolutionary Party stood for the goals of the Mexican Revolution. It included all important political groups and continues in power today. It was reorganized as the Party of the Mexican Revolution in 1938, and as the Institutional Revolutionary Party in 1946.

By the 1930's, the push for reform had slowed down. Calles and many other old leaders were now wealthy landowners and opposed extreme changes. Younger politicians called for speeding up the revolutionary program. As a result, the National Revolutionary Party adopted a six-year plan of social and economic reform. General Lázaro Cárdenas was named to carry it out.

After Cárdenas became president in 1934, he ended Calles' power. He divided among the peasants more than twice as much land as all previous presidents combined had done. He also promoted government controls over foreign-owned companies and strongly supported labor unions. In 1938, during a strike of oil workers, the government took over the properties of American and British oil companies. The companies and the British government protested angrily. But the U.S. government recognized Mexico's right to the properties as long as the companies received fair payment. In the 1940's, Mexico agreed to make payments to the companies.

The mid-1900's. Mexico's economy grew rapidly in the 1940's. Manuel Ávila Camacho, who was president from 1940 to 1946, did much to encourage industrial progress. World War II also contributed to the nation's industrial growth. Mexico entered the war on the side of the Allies in 1942. It sent an air force unit to the Philippines to fight the Japanese, but its contribution to the war effort was almost entirely economic. The country supplied raw materials and many laborers to the United States. It also made war equipment in factories that the United States helped set up. The value of Mexico's exports had nearly doubled when the war ended in 1945.

The Mexican economy continued to improve after the war. Industry and other economic activities expanded from the late 1940's through the 1960's. New factories made such products as automobiles, cement, chemicals, clothing, electrical appliances, processed foods, and steel. The government expanded highway, irrigation, and railroad systems. Many new buildings went up, especially in Mexico City. Agricultural exports from Mexico to the United States increased. A growing number of

U.S. tourists in Mexico also helped the economy.

Miguel Alemán Valdés served as president of Mexico from 1946 to 1952. He was followed by Adolfo Ruiz Cortines, who served from 1952 to 1958; Adolfo López Mateos, from 1958 to 1964; and Gustavo Díaz Ordaz, from 1964 to 1970. Under these leaders, Mexico maintained close relations with the United States.

The 1970's. Worldwide problems of recession and inflation led to a decrease in economic production and sharp increases in prices in Mexico during the 1970's. In 1976, Mexico's currency was devalued twice in an effort to stabilize the economy (see **Devaluation**).

Luis Echeverría Álvarez, who was president of Mexico from 1970 to 1976, increased government control over foreign-owned businesses. He also took steps that strained Mexico's friendship with the United States. For example, he improved Mexico's relations with the governments of Cuba and Chile in spite of U.S. opposition to those governments. Illegal immigration of Mexicans into the United States, plus drug smuggling from Mexico to the United States, caused more problems between the two countries. Echeverría also worked to make Mexico a leader among developing nations.

José López Portillo became president in 1976. He reduced government controls over both foreign and domestic businesses to encourage more private investment in Mexico. Relations between Mexico and the United States improved somewhat.

Vast petroleum deposits were discovered in Mexico during the 1970's. The country's petroleum production and its income from petroleum increased sharply. In the late 1970's, the government greatly increased spending on public works and industry to create more jobs.

Recent developments. In spite of Mexico's economic progress since 1940, many people remain poor. Many farmers still lack modern agricultural equipment and irrigation systems, and wages for farm laborers are low. Each year, more Mexicans move from farms to cities in search of jobs. This migration and Mexico's high rate of population growth have helped cause overcrowding and a shortage of jobs in the cities. Every year, many Mexicans move to other countries, especially the United States, to try to make a better living.

The Mexican government expected the income from petroleum to help balance its spending. But by 1981, decreased demand and lower prices for petroleum helped create an economic crisis in Mexico. The government became deeply in debt, and unemployment and prices rose sharply. In 1982, Miguel de la Madrid Hurtado became president. Mexico's economic problems continued. These problems worsened in the early 1980's, when thousands of refugees from El Salvador, Guatemala, and Nicaragua entered Mexico and settled in camps near the border in the Chiapas Highlands.

On Sept. 19 and 20, 1985, earthquakes struck south-central Mexico, including Mexico City. They caused about 10,000 deaths and $5 billion in property damage.

During the mid-1980's, opposition to the PRI grew. In 1988, the party's candidate, Carlos Salinas de Gortari, was elected Mexico's president in the closest election in many decades. Many people believed that Salinas won the election by fraud, and he entered office amid much criticism. That same year, an opposition coalition, the National Democratic Front, and an opposition party, the

© R. Gaillarde, Gamma/Liaison

Earthquakes devastated south-central Mexico in 1985, killing about 10,000 people. In Mexico City, *above,* the quakes destroyed many buildings and left thousands of people homeless.

National Action Party, won almost half of the seats in the Chamber of Deputies. As a result, the president no longer could rely on the vote of two-thirds of the Chamber of Deputies required to amend the Constitution.

Salinas promised to remove government restrictions on the economy and to reform Mexican politics. He attempted to stimulate economic growth and overcome Mexico's huge foreign debt by further reducing government ownership of businesses and by encouraging large-scale foreign investment in Mexico. Under these reforms, Mexico's economy improved, and Salinas's party won a huge majority of seats in the Chamber of Deputies in 1991 elections.

In 1993, Mexico, Canada, and the United States ratified the North American Free Trade Agreement (NAFTA). The treaty, which went into effect on Jan. 1, 1994, provided for the gradual elimination of trade barriers among Mexico, the United States, and Canada.

A few hours after NAFTA went into effect, rebels in the southern Mexican state of Chiapas began a revolt against the national government. Their spokesperson said the adoption of NAFTA was one reason why they revolted, claiming the treaty would harm them economically. However, the major cause of the revolt was the poverty and loss of land among farmers in their region. The rebel group called itself the Zapatista National Liberation Army. The rebels took control of four major towns in Chiapas. About 100 people were killed in fighting between the rebels and government troops. The government regained possession of the towns within a

week, and later declared a cease-fire. The Zapatistas continued to campaign against the poverty and discrimination faced by Mexico's Indian population.

In August 1994, Ernesto Zedillo Ponce de León of the PRI was elected president. Shortly after taking office in December, Zedillo faced an economic crisis during which the peso was devalued. An emergency economic plan and an international aid package helped ease the crisis in 1995, though the economy still struggled.

The Mexican government passed a series of election reforms in 1996. These reforms included provisions to help prevent vote fraud. In 1997, the PRI lost its majority in the Chamber of Deputies. In 2000, Vicente Fox Quesada of the National Action Party was elected president. He became the first non-PRI candidate to be elected to that office in 71 years. Roderic A. Camp and James D. Riley

Mexico, National Autonomous University of, is the largest university in Mexico. It was founded in 1551, in Mexico City, as the Royal and Pontifical University. The Roman Catholic Church operated the university until the government closed it in 1867. It was reopened in 1910 as the National University of Mexico. The university became *autonomous* (free of government control) in 1929. A new campus for the university was built during the early 1950's.

The university has an enrollment of more than 325,000. Courses are offered in law, philosophy, medicine, science, music, political and social science, commerce, engineering, architecture, and nursing.

P. A. McGinley

Mexico City landmarks include the towering Monument to Independence, *shown here,* honoring heroes of Mexico's independence movement. The monument stands at an intersection of a wide boulevard called the Paseo de la Reforma, the city's major street.

Mexico City

Mexico City is the capital of Mexico and one of the largest cities in the world. More than 8 million people live in Mexico City. More than 17 million live in the city's metropolitan area. Mexico City is the chief city in one of the world's most populous urban centers (see City [table: The 50 largest urban centers in the world]). The city is Mexico's center of commerce, higher education, industry, culture, and transportation.

Mexico City lies in central Mexico, about halfway between the Gulf of Mexico and the Pacific Ocean. The city has the same official boundaries as the Federal District of Mexico. The Federal District is a separate political area, similar to the District of Columbia in the United States. The built-up part of Mexico City occupies the northern section of the Federal District, and the rest of the district is rural. The metropolitan area has spread north into the state of México.

Mexico City has long dominated the country economically, politically, and culturally. It was the site of Tenochtitlan (pronounced *tay nohch TEE tlahn),* the capital of the Aztec Indian empire in the 1400's. Spain conquered the Aztec in the 1500's, and the city became the capital of Spain's colony in the Americas. Since Mexico became independent in 1821, Mexico City has served as the nation's capital.

As a political and economic center, the city is a magnet for ambitious Mexicans from all walks of life. Its attractions have contributed to its rapid growth and also to its problems. As more and more people moved from rural Mexico and other cities to the capital, government services could not keep pace with the growing population. In addition, the increase in the number of factories and automobiles in Mexico City created one of the world's worst air pollution problems.

Roderic A. Camp, the contributor of this article, is McKenna Professor of the Pacific Rim, Claremont McKenna College.

The city

Mexico City is built on ground that once was the lakebed of Lake Texcoco (pronounced *tay SKOH kohl).* Surrounded by mountains, the city sits in a natural basin that is 7,349 feet (2,240 meters) above sea level. Mexico City covers 571 square miles (1,479 square kilometers). The metropolitan area extends over about 900 square miles (2,330 square kilometers).

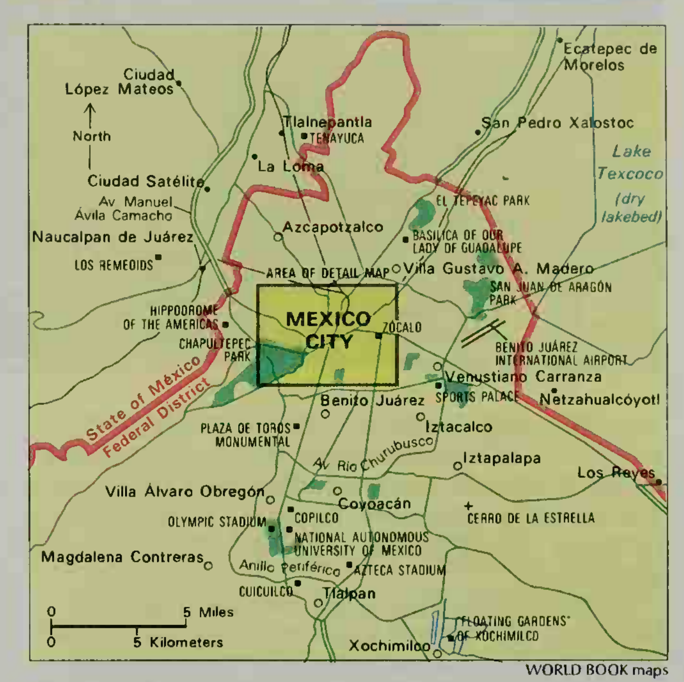
Downtown is the heart of Mexico City. Spanish architecture from the city's colonial period mixes with modern buildings in this section. The center of the downtown section has a layout common to Spanish colonial cities, with a major cathedral and government buildings surrounding a public square. The official name of the central square is Plaza de la Constitución (Constitution Plaza). But the square, as in many other cities in Mexico,

Facts in brief

Population: *City*—8,591,309. *Metropolitan area*—17,786,983.
Area: *City*—571 mi² (1,479 km²). *Metropolitan area*—about 900 mi² (2,330 km²).
Altitude: 7,349 ft (2,240 m) above sea level.
Climate: *Average temperature*—December, 54 °F (12 °C); May, 66 °F (19 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—29 in (74 cm). For the monthly weather in Mexico City, see Mexico (Climate).
Government: *Chief executive*—head of the Federal District of Mexico (elected by voters). *Term*—6 years.
Founded: 1325 (according to legend).

is usually called the Zócalo (Pedestal). The name came from a pedestal erected in the square in the 1840's to hold a monument that was never built. Facing the Zócalo are the City Hall; the Metropolitan Cathedral, Mexico's largest church; and the National Palace, which houses national executive departments and cabinet offices. Major government agencies with headquarters near the Zócalo include the Supreme Court of Justice and the Bank of Mexico.

The commercial areas downtown fill with people day and night. Some parts have been closed to automobiles, and pedestrians overflow the sidewalks onto the narrow streets. Historic churches, schools, and museums give the area a colonial flavor. Alameda Park, the downtown section's central park, lies about 1 mile (1.6 kilometers) west of the Zócalo along Avenida (Avenue) Juárez. This street, like several other places in Mexico City, was named for Mexico's President Benito Juárez, who enacted sweeping reforms in the 1850's and 1860's. A few blocks northeast of Alameda Park is Plaza de Garibaldi, where people come to hear the famous *mariachis,* strolling groups of musicians.



Residential and commercial centers have shifted from downtown to the city's southwest section. West of Alameda Park, Avenida Juárez crosses the city's major street, the Paseo de la Reforma (Boulevard of the Reform), named in honor of Juárez's reforms. Reforma is a wide, busy boulevard with beautifully landscaped circles at major intersections. The boulevard crosses the city on a northeast-southwest diagonal for most of its length. At one of its famous intersections stands the Monument to Independence, a golden angel on a tall column.

Reforma passes through Mexico City's largest and most popular park, Chapultepec Park (pronounced *chuh*

WORLD BOOK maps

The small map shows the location of Mexico City. The larger map shows the northern, urban part of the city and many of its points of interest. The southern part of Mexico City consists chiefly of mountains and rural areas.

Central Mexico City

This map shows the downtown area of Mexico City and surrounding residential and commercial neighborhoods.

WORLD BOOK map

Chapultepec Park is Mexico City's largest park. Every day, thousands of people come to the park to relax, picnic, and visit its many sights. At the entrance to the park zoo, *shown here,* families gather and vendors sell colorful balloons. The park also includes several of Mexico's leading museums.

© Haroldo de Farla Castro, FPG

PUHL tuh pehk). The park includes some of Mexico's leading art and history museums and Chapultepec Castle, the residence of some former Mexican presidents. The current presidential residence and working office is called Los Pinos (The Pines). It is in the southern section of the park.

Mexico City has many neighborhoods, called *colonias.* Some wealthy residential colonias lie west of the park, along the Paseo de la Reforma. Beautiful mansions line Reforma and shady streets in the Lomas de Chapultepec (Hills of Chapultepec) neighborhood. Exclusive shopping districts in the city include the Zona Rosa (Pink Zone), located south of Reforma, and Polanco, a colonia near Chapultepec Park. Suburban commercial centers line Reforma as it extends west.

Working-class and low-income residential areas sprawl in every direction from downtown Mexico City. Heavy industry is found in the city's northern regions.

The city's south side has become a center of culture. The National Autonomous University of Mexico and the College of Mexico are there. A wealthy colonia called Pedregal (Stony Ground) originated in the 1970's near the university on a field of lava rock left by a now-extinct volcano. Nearby is Perisur, a huge shopping center. Shopping and restaurants are also found along Avenida de los Insurgentes Sur (Avenue of the Insurgents South), a major commercial artery.

Metropolitan area. The Federal District of Mexico is bordered on three sides by the state of México and along its southern boundary by the state of Morelos. Rapid population growth along the México state border has greatly expanded border cities since the 1960's. One of these is Netzahualcóyotl *(NAY tsah wahl KOH YOHT uhl),* which lies east of Mexico City. Netzahualcóyotl has many poor people and serious environmental and health problems, and it lacks basic city services.

West of Mexico City, Reforma joins the highway to Toluca, capital of the state of México. Houses are built on steep hillsides along the highway. Mexico City's growth has spilled over most heavily into the state of México to the northwest, where many factories produce a wide variety of goods. North along the highway to Querétaro lies a middle-class suburb called Ciudad Satélite (Satellite City).

People

Ethnic groups. Most of Mexico City's people are *mestizos* (people of mixed white and Indian ancestry). They are descended from Spanish settlers and the Indians who were Mexico's original inhabitants. Residents mainly speak Spanish. Two percent of the city's people speak an Indian language, usually in addition to Spanish.

Immigrants from Europe, the Middle East, and Asia give Mexico City an international flavor. These ethnic groups contribute greatly to the intellectual, commercial, and cultural life of Mexico City.

About 85 to 90 percent of Mexico City's people are Roman Catholic. The city also has many Jews, Mormons, and Protestants.

Housing. A lack of affordable, good-quality housing is one of Mexico City's most serious problems. People have streamed into the city faster than homes could be built to accommodate them. Federally funded housing for low-income workers, begun in the 1970's, has eased the problem only slightly. Many residences lack safe drinking water, underground sewers, or utilities. Many homes are cardboard shacks, providing little protection. Many others are made from sheets of steel, tin, or other metal, or from asbestos panels. The city also has many middle-class areas with comfortable homes.

Most of Mexico City's buildings—private and public—are made of concrete blocks and cement. Wood is seldom used because it is scarce and expensive.

Education in Mexico City's public school system extends from the elementary grades through the university level. It is supervised by the national government. Most of the schools are seriously underfunded. Many parents who can afford to do so send their children to private schools. The city has many private schools. Most of them are operated by the Roman Catholic Church, though some immigrant groups also have schools.

The capital has more institutions of higher education than anywhere else in the country. Mexico's oldest and largest university is the National Autonomous University

of Mexico. Other important schools are the College of Mexico, the National Polytechnic Institute, the Autonomous Technological Institute of Mexico, and the Ibero-American University.

Cultural life and recreation. Mexico City is Mexico's intellectual and cultural center. Many of the country's leading artists and writers live there. The city's most internationally famous group of performers is the Ballet Folklórico. This dance company performs traditional dances in colorful costumes at the Palacio de Bellas Artes (Palace of Fine Arts). The Bellas Artes, a majestic building near Alameda Park, is a performance and exhibition center. The Bellas Artes and many other public buildings in the city are decorated with large murals. The National Palace features a series of murals by Diego Rivera, one of Mexico's most famous painters.

The National Museum of Anthropology, in Chapultepec Park, is one of the world's greatest museums. It displays artworks of the Aztec, Maya, and other ancient Mexican cultures. Also in the park are the Museum of Modern Art and the Tamayo Museum of Contemporary International Art, named for the famous Mexican painter Rufino Tamayo. The Museum of the City of Mexico, near the Zócalo, offers a history of the capital.

Mexico's National Archives are downtown. The city's two most important libraries are at the College of Mexico and the National Autonomous University of Mexico.

Mexico City has baseball, boxing, bullfighting, football, horse racing, jai alai, soccer, swimming, tennis, and many other sports. Soccer is the most popular team sport. In any neighborhood, rich or poor, adults and children can be seen playing the game.

Many people leave the city on weekends. They seek clean air and lush vegetation in such places as Cuernavaca *(KWEHR nuh VAHK uh)*, a beautiful city to the south, or Valle de Bravo, a mountain retreat to the west. At the archaeological site of Teotihuacán, people climb towering pyramids for a spectacular view of the ancient Indian city.

Social problems. Mexico City has great difficulty providing adequate schools, transportation, and other public services for its huge population. The city also has

The National Museum of Anthropology houses such ancient Indian artworks as this sculpture of an Aztec goddess.

a serious crime problem, especially in low-income neighborhoods. Also, many police and other government officials have been accused of corrupt practices, such as accepting bribes and engaging in criminal activities themselves. Alcoholism, drug addiction, and juvenile delinquency are other serious difficulties in the city.

The city's large number of people creates transportation difficulties. Many workers live far from their jobs and travel an average of about two hours per day to and from work. Because few highways bypass the city, long-distance travelers must drive through it, adding to overcrowded streets. A beltway system to separate local traffic from through traffic has been started.

Environmental problems. Air pollution is Mexico City's most dangerous environmental problem. It is so serious that sometimes children must stay indoors when the government announces air-quality warnings. Many people suffer from breathing problems and eye irritation. The city lies in a bowl-shaped valley. The surrounding mountains keep the wind from blowing away factory smoke, car exhaust, and other pollutants. The government has tried to control pollution from cars by closing some downtown streets to traffic. The city also bans about one-fifth of its cars from the road each day of the workweek, with the day a car cannot be driven determined by its license number. In the 1990's, the government began to impose even stricter pollution controls.

Economy

The Mexico City area ranks first in the country in manufacturing activities and in retail business. It is also the leading center of financial and professional services. The city is the center for Mexico's commercial activity and a major tourist area. In fact, the country's economic development is so concentrated in the Mexico City area that the federal government wants to draw business and industry to other parts of Mexico.

Industry. Mexico City accounts for about half of Mexico's manufacturing activity and almost half of its factory workers. Other major employers are petroleum and mineral refineries and construction companies. About 40 percent of Mexico's technical and research special-

ists live in Mexico City.

The federal government ranks as one of the city's chief employers. Many college graduates in architecture, economics, engineering, law, and other fields pursue careers in government. To relieve crowding in Mexico City, the government sought in the 1980's to move federal agencies away from the capital. But few agencies actually relocated.

Finance. Mexico City is the financial center of the nation. More than half of all the country's bank transactions take place there. In 1982, the government took control of all Mexican banks, but it began selling them back to private owners in 1991.

Transportation. Mexico City's location has made it the transportation hub of Mexico. Railroads and highways radiate from the city like spokes of a wheel. It is hard to travel north or south in Mexico without passing through the capital. Passenger rail service is extensive in Mexico, but most travel is done by bus. Benito Juárez International Airport, east of downtown, handles direct flights to and from many countries and other Mexican cities. The Federal District has many local bus routes and one of the world's best subway systems. Although subway and bus routes are added continually, the huge population causes buses and subways to be crowded.

Communication. Mexico City is the country's radio and television broadcast center. Televisa, which has offices in the downtown area, ranks as the largest privately owned television network in Latin America. It broadcasts on various channels in the city and throughout the country and even reaches many parts of the United States. Mexico City publishes more daily newspapers per person than any other city in the world. With 14 dailies, the competition for readership is fierce. A well-read resident of Mexico City may subscribe to half a dozen papers representing various political viewpoints.

City government

The mayor of Mexico City is also the chief official of the Federal District. The mayor's official title is *Jefe de Gobierno*—that is, head of government. The office of Mexico City mayor is considered to be the second most important political office in Mexico, after the president. Voters elect the mayor to a six-year term.

Voters in Mexico City also elect a legislative assembly made up of 66 deputies from the various wards of the city. The mayor may present laws or decrees for consideration by the assembly. The voters of the Federal District elect senators and deputies to serve in the two houses of Mexico's General Congress, as do the voters of Mexico's 31 states.

History

City of the Aztec. By 2000 B.C., farm villages had developed in the Lake Texcoco region. The Aztec Indians founded their capital, Tenochtitlan, on an island in the middle of the lake. According to Aztec tradition, Tenochtitlan was founded in 1325. But modern scholars believe it was founded somewhat later. From this magnificent city, the Aztec ruled a vast empire during the 1400's. By the early 1500's, the city and its suburbs had a population of about 300,000.

In 1519, the Spanish explorer Hernando Cortés marched on Tenochtitlan. He and his men were welcomed into the city by the Aztec emperor, Montezuma, who may have thought Cortés was a god or the representative of a god. Cortés imprisoned Montezuma and took control of the city. In 1520, the Aztec forced the Spaniards out. Cortés returned with a larger force, conquered the city, and destroyed it in 1521.

Spanish rule. Cortés rebuilt the city, creating a Spanish capital over the ruins. Almost all traces of Aztec architecture were destroyed. Mexico City became the capital of a Spanish colony called New Spain. The colony at its peak extended from present-day Central America to the state of Kansas in the United States. The city regained its former size and grew into the largest city in the Western Hemisphere. After about 30,000 people died in floods in 1629, the Spaniards improved the canal and dike system for draining Lake Texcoco.

Independence. Mexico became independent from Spain in 1821. In 1846, Mexico went to war with the United States over disputed territories. In 1847, Mexico City was captured by U.S. troops after the Battle of Chapultepec. In that battle, six military students were said to have jumped from Chapultepec Castle to their deaths rather than surrender. The Monumento a los Niños Héroes (Monument to the Boy Heroes) stands in Chapultepec Park in their honor. United States troops occupied the city until the war ended in 1848. See **Mexican War.**

In 1863, Mexico City fell to invading French troops. From 1864 to 1867, Mexico was governed by an Austrian-born monarch, Maximilian, who gained the throne with the support of France and of Mexican conservatives. Maximilian had the Paseo Imperial (Imperial Boulevard) built to link the National Palace at the Zócalo with his residence, Chapultepec Castle. The Paseo Imperial was later renamed the Paseo de la Reforma.

General Porfirio Díaz came to power in 1876 and ruled as a dictator. He modernized Mexico City and added many architectural landmarks. One of the most dramatic of these landmarks began as his legislative palace but became the Monument to the Revolution, honoring his overthrow in 1911. Díaz also began the Palacio de Bellas Artes in 1904, though it was not completed until 1934.

Revolution and growth. The Mexican Revolution began in 1910 in opposition to Díaz, forcing him out of office the next year. In February 1913, Mexico City again became the scene of fighting as troops rebelled against the elected president, Francisco I. Madero. This period of fighting became known as the *Decena Trágica,* the Tragic Ten Days. Madero was murdered, and Victoriano Huerta ruled as a dictator until he too was overthrown. For the next several years, revolutionary leaders struggled among themselves for power.

From the 1940's to about 1970, Mexico had an economic boom. Large-scale public works contributed to this boom and to Mexico City's modernization. About 3 million Mexicans migrated to the capital. This steady flow of people contributed to the city's rapid growth but also to its social and economic problems. After several years of slower economic growth in the early 1970's, the discovery of vast petroleum deposits in Mexico brought a brief return to prosperity.

Recent developments. In the 1980's, world oil prices and the demand for oil began to drop, triggering a major economic crisis that severely affected Mexico City.

The Mexican government had trouble paying its debts. Many residents of Mexico City lost their jobs because of government cutbacks.

In 1985, a major earthquake with strong aftershocks struck south-central Mexico, including Mexico City, causing about 10,000 deaths. Damage was especially severe because the city had been built on the moist clay soil of a former lakebed. During an earthquake, such soil transmits powerful vibrations and acts like jelly, causing buildings to collapse. About 400 buildings in Mexico City were destroyed, and thousands of others suffered damage. After the quakes, the city enacted tougher building codes and safety standards.

In 1991, the government stepped up efforts to improve the city's air quality. It closed dozens of firms for violating environmental laws.

In 1995, Mexico faced another economic crisis after the value of Mexico's currency fell sharply. Mexico City's crime rate increased dramatically during this time.

In 1997, voters in Mexico City elected a mayor for the first time. Previously, the district had been governed by an official called the *regente,* who was appointed by Mexico's president and functioned as a mayor.

Additional resources

Caistor, Nick. *Mexico City: A Cultural and Literary Companion.* Interlink Bks., 2000.

Coe, Andrew. *Mexico City.* 2nd ed. Odyssey Pubns., 1999. A guidebook.

Meyer, Julius Lothar (1830-1895), a German chemist, showed the relation between the atomic weights and properties of the elements. He and the Russian chemist Dmitri Mendeleev independently developed a *periodic table,* which grouped the elements by their atomic weights and properties (see **Element, Chemical** [Periodic table]). Meyer also concluded that elements were composed of several kinds of smaller particles. This idea led other scientists to study the structure of atoms.

Meyer was born on Aug. 19, 1830, in Tübingen. He was a professor of chemistry at the University of Tübingen from 1876 until his death. Seymour Harold Mauskopf

See also **Chemistry** (Formation of the periodic table).

Meyerbeer, Giacomo (1791-1864), was one of the most popular opera composers of his day. He was born on Sept. 5, 1791, in Berlin but achieved his greatest success while composing in Paris. Meyerbeer had an acute sense for building stunning climaxes and for creating spectacular effects. Richard Wagner's early operas owe much to the influence of Meyerbeer's music.

The trend in French opera during the 1830's and 1840's was toward grand opera, which emphasized many performers on stage and impressive stage effects. Meyerbeer used this stress on the spectacular in his first Paris opera, *Robert-le-Diable* (1831), which gained him immediate fame. This work was followed by *Les Huguenots* (1836) and *Le Prophète* (1849). *L'Africaine,* perhaps his most interesting opera, was first performed in 1865, after his death. Thomas Bauman

Mfume, *oom FOO may,* **Kweisi,** *kwah EE see* (1948-), became president and chief executive officer of the National Association for the Advancement of Colored People (NAACP) in 1996. He resigned from the United States House of Representatives to accept the position.

Mfume, a Maryland Democrat, had been a member of the House since 1987. From 1992 to 1994, he served as chairman of the Congressional Black Caucus, an organization of African American members of Congress that promotes the interests of blacks. In 1994, he was appointed to the Democratic Policy Committee, which controls committee assignments for House Democrats.

NAACP

Kweisi Mfume

In Congress, Mfume promoted interests of the poor. In 1993, for example, he helped pass legislation that made more people eligible for food stamps and increased the availability of immunizations for uninsured children.

Mfume was born Frizzell Gray on Oct. 24, 1948, in Baltimore. He later adopted his present name, an African name meaning *Conquering Son of Kings.* He earned a B.S. degree from Morgan State University in 1976 and an M.A. degree from Johns Hopkins University in 1984. Jackie Koszczuk

Miami, *my AM ee,* Florida (pop. 362,470; met. area pop. 2,253,362), is a world-famous resort city. Its recreational areas and warm weather attract millions of visitors yearly. Miami is on Florida's southeast coast at the mouth of the Miami River. The city lies on Biscayne Bay, about 3 $\frac{1}{2}$ miles (5.6 kilometers) west of the Atlantic Ocean. Miami is Florida's second largest city. Only Jacksonville has more people.

The city. Miami, the county seat of Miami-Dade County, covers about 54 square miles (140 square kilometers), including 20 square miles (52 square kilometers) of inland water. The heart of downtown Miami is the intersection of Miami Avenue and Flagler Street. County government buildings stand nearby.

The Miami metropolitan area covers all of Miami-Dade County—2,020 square miles (5,232 square kilometers). The metropolitan areas of Miami and Fort Lauderdale form the Miami-Fort Lauderdale Consolidated Metropolitan Statistical Area.

Two-thirds of Miami's population is of Hispanic origin. Cubans make up more than half of that group, and they give the city a strong Latin culture. This culture has attracted many banks and companies that handle Latin American trade. The city also has a large Haitian population. Other population groups include those of English, German, and Italian descent. About a fourth of the people in Miami are African Americans.

Economy of the Miami metropolitan area depends mostly on tourism, which produces billions of dollars annually. The city's temperature varies little, averaging 81 °F (27 °C) in summer and 71 °F (22 °C) in winter. For the monthly weather in Miami, see **Florida** (Climate).

The Miami metropolitan area has about 3,000 light manufacturing plants. The city is one of the largest cen-

Miami lies on the southeast coast of Florida. Recreational facilities and warm weather help make Miami a world-famous resort city. Hotels and residential buildings line Brickell Key, *foreground.* Office towers rise in the city's downtown area, *background.*

ters in the country for the production of clothing. Other products include furniture, metal goods, printed materials, and transportation equipment.

Miami International Airport is one of the nation's busiest terminals. The airport serves as the main air gateway between the United States and Latin America. The Port of Miami handles passenger and cargo ships from many countries. Passenger trains also serve the city. One daily English-language newspaper—*The Miami Herald*—and one Spanish-language daily—*Diario Las Americas*—are published in Miami.

Education. The Miami-Dade County public school system operates nearly 300 elementary and secondary schools. About 325 private and church-supported schools serve the area. Institutions of higher learning in the area include Barry University, Florida International University, Florida Memorial College, St. Thomas University, and the University of Miami. The University of Miami's Rosenstiel Institute of Marine and Atmospheric Sciences is an important center of ocean study.

Cultural life and recreation. Miami has an opera company, two dance companies, and several art galleries and theaters. The downtown Miami-Dade Cultural Center houses the main library, the Miami Art Museum, and the Historical Museum of Southern Florida. Other points of interest in the Miami area include Fairchild Tropical Garden, Lowe Art Museum, Metrozoo, the Seaquarium, and Vizcaya Museum and Gardens.

Many visitors come to the Miami area for the Orange Bowl football game on or near New Year's Day. The metropolitan area is also the home of the Miami Dolphins of the National Football League, the Florida Marlins National League baseball team, the Miami Heat of the National Basketball Association, and the Florida Panthers of the National Hockey League.

Government. Miami has a commission-manager government. The voters elect a mayor and five commissioners to four-year terms. The commission appoints a city manager to direct various government services.

Miami is also governed by a metropolitan county government. The 13-member Miami-Dade County Board of Commissioners heads the metropolitan government. It administers pollution control, transportation, and other activities that affect the entire county.

History. Tequesta Indians lived in what is now the Miami area long before white settlers first arrived. In 1895, Julia D. Tuttle, a Florida pioneer, convinced railroad builder Henry M. Flagler that the area could become rich farmland. She sent him some flowers to show that the land had escaped a killing frost. In 1896, Flagler extended the Florida East Coast Railroad to the area in exchange for land. That same year, Miami was founded and received a city charter. About 1,500 people lived there. The railroad helped Miami's population reach 5,000 by 1910 and 30,000 by 1920.

During the early 1920's, a great real estate boom centered in Miami. People made and lost fortunes with the construction of homes, hotels, and resorts. Just as the boom began to decline in 1926, a destructive hurricane struck the city. Another severe storm hit in 1928. Even so, Miami's population reached 110,000 by 1930.

After the United States entered World War II in 1941, Miami served as an important military training center. The armed services used most of the city's hotels as barracks. Many service personnel settled in Miami after the war ended in 1945. By 1950, the city had 250,000 people.

Since 1959, when Fidel Castro became dictator of Cuba, hundreds of thousands of Cubans have fled to Miami, about 200 miles (320 kilometers) away. In the late 1970's, many refugees from Haiti also began settling in the Miami area.

In 1973, Maurice Ferre took office as Miami's mayor, becoming the first Hispanic mayor of a large U.S. city. Ferre, who was born in Puerto Rico, served as mayor until 1985. That year, he lost a bid for reelection to Xavier L. Suarez, who became the city's first Cuban-born mayor. Suarez held the office until 1993.

Like many other large cities, Miami faces unemployment and housing shortages, which especially affect the African American population. In 1980, racial tension erupted into violence after four white former county policemen were found not guilty of killing a black Miami businessman. Several other such incidents caused similar unrest during the 1980's and early 1990's.

In the mid-1980's, many new buildings rose in Miami. A rapid transit system, Metrorail, began operating in 1984. Metromover, a downtown monorail line, was added in 1986.

In 1992, Hurricane Andrew hit Florida. Areas south of Miami, especially Homestead, were severely damaged.

In November 1997, Xavier Suarez again won election as mayor, defeating Mayor Joe Carollo. In March 1998, however, a Miami-Dade County circuit judge voided the election because of voter fraud. An appeals court then proclaimed Carollo the winner. Carollo lost in a bid for reelection in 2001.

Miami became the focus of world attention in late 1999 when a controversy erupted over the custody of a 6-year-old Cuban shipwreck survivor, Elián González. Elián's relatives in Miami sought political asylum for the boy. But Elián's father demanded that the boy be returned to him in Cuba. In April 2000, armed federal agents seized Elián, enforcing a government order that the boy be returned to his father (see **Hispanic Americans** [Cuban immigration]). Peter O. Muller

Miami Beach, *my AM ee,* Florida (pop. 87,933), a famous resort center, lies on an island $2\frac{1}{2}$ miles (4 kilometers) across Biscayne Bay from the city of Miami. The island measures 10 miles (16 kilometers) from north to south and is 1 to 3 miles (1.6 to 5 kilometers) wide. Four causeways link it with the mainland (see **Miami** [map]).

Tourism is the major industry of Miami Beach. The city's many hotels, tropical climate, white sandy beaches, and recreational areas help attract over 2 million tourists annually. Tropical trees and shrubs line its streets, and gardens of brilliant flowers border its green lawns. Miami Beach features many buildings designed in the Art Deco style popular in the 1920's and 1930's.

Tequesta Indians lived in the Miami Beach area in the

1400's. A Spanish mission was built in 1567. An attempt by businessmen to start a coconut plantation failed in the 1880's. But John S. Collins, one of the businessmen, pioneered in developing the resort city. Other city founders include Carl G. Fisher, Thomas J. Pancoast, and John N. Lummus. In 1912, rock and sand were pumped from the bottom of Biscayne Bay and spread over mangrove roots and soft sand to create the modern city. Miami Beach was incorporated as a town in 1915. It was incorporated as a city in 1917. The city has a council-manager government. Rick Hirsch

Miami Indians are a tribe that lived in several areas near the Great Lakes. They were divided into six bands. Two of the bands, the Wea and the Piankashaws, became independent tribes in the early 1800's.

When white explorers first encountered the Miami in the mid-1600's, the tribe lived in the area of present-day Green Bay, Wisconsin. The Miami then moved south to areas along the Wabash, Great Miami, and Maumee rivers in what are now Illinois, Indiana, and Ohio.

The Miami resembled the Illinois Indians in their language and customs. They lived in dome-shaped wigwams. Their villages were surrounded by large fields of corn, which was the tribe's chief crop.

The Miami had a reputation as skilled warriors. But much of their success in war came from their clever choice of allies. They formed shifting alliances with the French, the British, and neighboring tribes. In 1763, some Miami helped the Ottawa chief Pontiac fight the British in a conflict known as Pontiac's War. During the Revolutionary War in America (1775-1783), however, the Miami sided with the British because they opposed the expansion of American settlers into their lands.

The Miami and allied tribes, known as the Miami Confederacy, fought against U.S. forces in the Indian wars of the Ohio Valley in the 1790's. Under their most famous war chief, Little Turtle, the Indians won several major battles. However, Major General "Mad Anthony" Wayne defeated the Miami Confederacy in 1794 at the Battle of Fallen Timbers.

In 1846, the U.S. Army tried to force many of the Miami to leave Indiana. Some members of the tribe escaped from the Army and remained in the state. Others were allowed to stay. Those who left eventually settled in Oklahoma. Today, about 3,000 Miami still live in Indiana. About 1,200 members of the tribe make their homes in Oklahoma. Terry P. Wilson

Mica, *MY kuh,* is the name of a group of minerals that contain atoms of aluminum, oxygen, and silicon bonded together into flat sheets. Mica has perfect *cleavage*—that is, it splits cleanly into thin sheets or layers. These sheets of mica are tough, flexible, and elastic. Mica may be colorless, black, brown, green, or violet.

The chief kinds of mica, in order of abundance, are (1) muscovite, (2) biotite, (3) phlogopite, and (4) lepidolite. They differ according to the atoms of various substances that occur in layers between the aluminum-oxygen-silicon sheets and hold the sheets together.

Muscovite contains aluminum and potassium. It is usually colorless but may be pale green. Muscovite got its name because Russians, or "Muscovites," once used it as window glass. Biotite contains iron, magnesium, and potassium and is black. Phlogopite has magnesium and potassium and is pale brown or colorless. Lepidolite contains aluminum and lithium and is pale violet.

Mica is produced in the form of large sheets or in small pieces called *scrap mica* or *flake mica.* India is the leading producer of sheet mica, followed by Brazil and Madagascar. Sheet mica is used in a variety of electrical and electronic products.

Scrap mica is important in many industries. The United States is the largest producer of scrap mica. Most U.S. mica comes from North Carolina, followed by New Mexico and South Dakota. Maria Luisa Crawford

Micah, *MY kuh,* **Book of,** is a book of the Hebrew Bible, or Old Testament, named for a Hebrew prophet. Micah lived about 700 B.C., during the reign of King Hezekiah of Judah. *Micah* means "Who is like the Lord?"

The first part of the Book of Micah contains prophecies of punishment against Samaria and Jerusalem for the corruption of their leaders. It also includes prophecies of salvation that say Mt. Zion, the holy mountain in Jerusalem, will be the sacred center where universal peace shall one day spring. The second part of the book contains judgments focusing on the broken relationship between God and Israel, and hopeful prophecies of God reestablishing His love of His people. Famous passages include the summary of true religion (6: 8) and the expectation of the Messiah from Bethlehem (5: 2-5).

The contrast between Micah's prophecies of doom and hope has led scholars to argue that the original book was a collection of speeches from the time of Hezekiah. A group of sayings was probably added later, after the Babylonian Exile, which ended in 538 B.C.

Eric M. Meyers

Mice. See Mouse.

Michael, Saint, is one of the four archangels in both Jewish and Christian scriptures. He is considered the patron angel and guardian of Israel. In art, he is usually portrayed as a warrior. In Revelation 12: 7-9, Michael and his angels fight a dragon. Later tradition identifies him as the angel mentioned in Acts 7: 38 who gave the law to Moses on Mount Sinai. His feast day is the festival of Michaelmas—on September 29 in the West and on November 8 in the Eastern Orthodox Churches. See also **Michaelmas.** Richard A. Edwards

Michaelmas, *MIHK uhl muhs,* is a festival held on September 29 in the Roman Catholic and Anglican churches, and on November 8 in the Greek, Armenian, and Coptic churches. The feast honors Saint Michael the archangel (see **Michael, Saint**). Michaelmas probably originated in the Roman Empire in the A.D. 400's. The festival was particularly important during the Middle Ages when Saint Michael was the patron saint of knights and also one of the patron saints of the Roman Catholic Church.

In the United Kingdom and several other countries, Michaelmas is one of the four quarter days of the year when rents and bills come due. It is also the beginning of a quarterly court term and an academic term at Oxford and Cambridge. The British celebrate Michaelmas with meals of roast goose, a custom that started hundreds of years ago when people included a goose in their rent payments. An English proverb says, "If you eat goose on Michaelmas Day you will never want money all the year round." David G. Truemper

The Sistine Chapel was probably Michelangelo's greatest achievement as a painter. A detail of the ceiling fresco, *above,* shows God creating the sun, the moon, and vegetation.

Michelangelo

Michelangelo, *MY kuhl AN juh LOH* or *MIHK uhl AN juh LOH* (1475-1564), was one of the most famous artists in history. He was mainly interested in creating large marble statues, but his endless creative energy also led him to become a great painter and architect as well as a poet. He was also one of the most famous people of his time and a great leader of the Italian Renaissance, a period marked by a rebirth of interest in the art and learning of ancient Greece and Rome.

Michelangelo is best known for his treatment of the human body in painting and sculpture. His figures convey a sense of grandeur and power, and arouse strong emotions in many spectators. In size, strength, and emotional intensity, these figures go beyond real people. Michelangelo's figures are both animated and restrained, and seem to possess great spiritual energy. His work presses toward the extremes of heroism and tragedy but is never false or artificial.

Early life. Michelangelo was born on March 6, 1475. His full name was Michelangelo Buonarroti. He came from a respectable Florence family and was born in the village of Caprese, where his father was a government agent. Michelangelo had a brief classical education that dealt with the literature, art, and life of ancient Greece and Rome. When he was 12 years old, Michelangelo became an apprentice to the most popular painter in Florence, Domenico Ghirlandajo.

Before his apprenticeship was completed, Michelangelo stopped painting and began working as a sculptor under the guidance of a pupil of the sculptor Donatello. Michelangelo attracted the support of the ruler of Florence, Lorenzo de' Medici, who invited the young artist to stay at his palace. Michelangelo's earliest surviving sculpture is a small unfinished relief of a battle, done when he was about 16. This work shows the obvious influence of ancient Roman marble sculpture belonging to Lorenzo. But the relief also shows the force and movement that became typical of Michelangelo's style. During these years, he began the study of anatomy.

After the Medici family lost power in 1494, Michelangelo began traveling. He lived in Rome from 1496 to 1501. There he had his first marked success when he carved in marble a life-sized statue of the Roman wine god Bacchus. At 23, Michelangelo carved a version of the traditional Pietà subject, the dead Christ in the lap of the mourning Virgin Mary. Both figures are larger than life-sized. This statue, now in St. Peter's Basilica in Rome, established him as a leading sculptor. The work was plainer and less decorative than most statues of the time, and thus looked stronger and more solemn.

Michelangelo returned to Florence in 1501 and remained there until 1505. He may have gone there to compete for the right to work on a large piece of marble that had been abandoned by earlier sculptors working on the Cathedral of Florence. The marble became Michelangelo's *David* (1504), one of the most famous works in the history of art. See the picture of the statue in the **David** article.

Michelangelo's *David* portrays the Israelite king partly as an ideal man, partly as an adolescent youth. The young figure faces his foe tensely but confidently, with a bold scowl and his sling at the ready.

The Florentines had planned to put the statue high in the air on the Cathedral of Florence. But they decided instead to place this great work of art at eye level in their main public square, and it became a symbol of the new republic that had replaced Medici rule.

The new democratic government of Florence then asked Michelangelo and the city's other outstanding artist, Leonardo da Vinci, to create large battle scenes for the walls of the city hall. Michelangelo probably never started to paint the wall, but his design for the work is known to us through his sketches and through copies

Marble sculpture (about 1550); Duomo, Florence (SCALA/Art Resource)

The Florentine *Pietà* was intended for Michelangelo's own tomb. The hooded figure helping to hold the body of Christ is a self-portrait of the sculptor when he was about 75 years old.

by other artists. It displayed his expert ability to render human anatomy. It was during these years that Michelangelo formed the basis of the style in which he would work for the rest of his life.

From about 1505 on, Michelangelo devoted nearly all his time to large projects. In his enthusiasm for creating grand and powerful works of art, he accepted projects that were far too large for him to complete. The first one was a tomb ordered by Pope Julius II that was to include 40 marble statues. The artist accepted the job in 1505 and ended the project unsuccessfully 40 years later.

The Sistine Chapel. Julius II was a patron of the arts with a sweeping imagination equal to Michelangelo's. Julius gave Michelangelo a more practical commission, painting the *vault* (arched ceiling) of the Sistine Chapel in the Vatican. This project became Michelangelo's most famous work.

The Sistine Chapel is where major papal ceremonies take place. The chapel was built by Pope Sixtus IV, Julius II's uncle, and was decorated during the 1480's with paintings by some of the greatest artists of the time, including Sandro Botticelli, Luca Signorelli, and Perugino. All of its decoration together shows the history of the world according to the Bible. The earlier painters showed the lives of Moses and Jesus Christ and the sequence of the popes. Michelangelo's contribution to the project was the grandest of all.

On the lowest part of the vault of the Sistine Chapel as well as on the upper walls, over the arched windows, Michelangelo painted *The Ancestors of Christ.* In the corners, he portrayed stories of the salvation of the Jewish people, such as *David and Goliath* (see **David** [picture: David and Goliath]).

The highest part of the vault was originally painted blue with gold stars, symbolizing heaven. Michelangelo changed this treatment. Above the *Ancestors,* he painted great thrones in which are seated prophets believed to have foretold the coming of a *Messiah* (savior). Male prophets of the Old Testament or Hebrew Bible alternate with *sibyls,* female prophets of ancient times. The series of prophets ends above the high altar of the chapel with Jonah, who survived after three days inside a whale, an event that foretells Christ's death and Resurrection. For examples of these paintings, see the pictures with **Isaiah, Book of; Jeremiah, Book of.**

Above the thrones of the prophets are nude figures, called *ignudi,* who hold bronze-colored disks with stories taken mostly from the Books of Kings. Michelangelo covered the very top of the vault with nine scenes from the Book of Genesis, including three scenes portraying the creation of the universe, three showing the creation of Adam and Eve and their fall from grace, and three illustrating the story of Noah. The most famous scene is *The Creation of Adam* (see **Painting** [picture: *The Creation of Adam*]).

Michelangelo, forced against his own wishes by Julius to undertake the huge task, began the ceiling in 1508 and completed it in 1512. He used a technique called *fresco,* applying the paint to damp, freshly laid plaster and working quickly before the plaster dried. He began at the entrance and worked toward the altar, starting with the scenes from Noah's life and working backward in time to the beginning of creation. Michelangelo painted the ceiling from a scaffolding, standing up, not lying on his back as historians once thought. During this period, he wrote a satirical poem in which he complained of a stiff neck and of paint dripping into his eyes. In the margin of the page, he drew a caricature of himself reaching up to paint.

At first, Michelangelo approached the task in a style resembling his earlier works. But he soon gained confidence and developed new ways of showing tension and power. The last frescoes he painted, which include *The Separation of Light from Darkness* and the portrait of Jonah, are much richer and more active compositions. The figures in these last paintings are also larger and freer in execution.

When the frescoes of the Sistine ceiling were cleaned in the 1980's, restorers found that Michelangelo had painted in much brighter colors than had been realized. The brilliance of the colors makes the paintings visible from a great distance. The top of the vault is about 70 feet (21 meters) above the floor.

The tomb of Julius II. After he had finished the ceiling, Michelangelo resumed work on the pope's tomb. He carved three famous figures that resemble the painted prophets and decorative figures on the Sistine ceiling. These figures are Moses and two prisoners, sometimes called *The Heroic Captive* and *The Dying Captive,* completed by 1516. The figure of Moses, who seems to be filled with terrible anger, was later used as the centerpiece of the tomb. This statue was finally placed in the Church of St. Peter in Chains in Rome. The figures of the two captives may symbolize lands conquered by Julius II or arts and sciences left without sup-

Fresco (1550); The Vatican Museums (SCALA Art Resource)

The Crucifixion of Saint Peter, *left,* was completed by Michelangelo when he was 75. This fresco and a companion work, *The Conversion of Saint Paul,* were his last paintings. They were commissioned by Pope Paul III for a chapel in the Vatican.

The Medici Chapel, *below,* contains tombs for two princes of the Medici, a ruling family of Florence. Michelangelo created the statues and also designed the architecture. The figures *Evening* and *Dawn* recline on the tomb of Lorenzo de' Medici at the left.

Interior and marble sculptures (1515-1534); San Lorenzo, Florence (SCALA Art Resource)

Marble sculpture (1498-1499); St. Peter's Basilica, Vatican City (SCALA/Art Resource)

Two Pietàs span Michelangelo's career. The *Pietà, above,* was the most important work of his youth and established his reputation. The stark, unfinished Rondanini *Pietà, right,* dates from 1564, the year of his death.

Marble sculpture; Castello Sforzesco, Milan (SCALA/Art Resource)

port after his death. One of them struggles violently against his bonds as the other languishes and seems to submit to defeat.

The Medici Chapel. Michelangelo spent the years from 1515 to 1534 working mainly for the Medici family, who had regained control of Florence. He designed and carved tombs for two Medici princes and also designed the Medici Chapel, in which the tombs are placed. Michelangelo left the chapel incomplete when he moved away from Florence in 1534.

Along with the statues of the two young princes, the tombs include the figures of *Night* and *Day* on one tomb and *Evening* and *Dawn* on the other. The figures recline on curving lids, conveying a sense of fate or individual tragedy. They make a great impact on spectators as a significant observation about human destiny. Some read the parts of the monument from floor to ceiling as a symbol of the rising of the soul after its release from the body. Others see the four statues on the curved lids as a sign of the endless movement of time, in which life is only an incident. The tomb containing *Night* and *Day* is reproduced in the **Sculpture** article.

Michelangelo also designed the architecture of the Medici Chapel. He planned the walls like a carved relief, with projections and hollows and long, narrow shapes to give an elongated effect. This approach, resembling carved architecture, is carried further in the entrance hall and staircase to the Laurentian library in Florence, which he designed between 1524 and 1559.

The Last Judgment. Michelangelo was sometimes torn between loyalty to the Florentine republic and loyalty to the Medici family, his patrons. In the late 1520's, the Medici family once more lost power in Florence. The city fortified itself against an attempt by the family to regain control. Michelangelo served as director of fortifications. In 1530, the Medici family took the city by force, and Michelangelo went into hiding to avoid arrest. However, Pope Clement VII, himself a member of the Medici family, sent word to Florence that Michelangelo was to be treated well and allowed to continue working on the Medici tombs. Michelangelo resumed his work, but he left Florence in 1534. He never returned to the city, though he was buried there.

Michelangelo settled in Rome, where he worked for Pope Paul III. From 1536 to 1541, Michelangelo painted the fresco of *The Last Judgment* for the altar wall of the Sistine Chapel, destroying some of his earlier *Ancestors of Christ* to do so. In a single scene covering the entire wall, Michelangelo showed the resurrection and judgment of humanity.

At the top of *The Last Judgment* are wingless angels with the cross upon which Christ died. Beneath them, the blessed gather in heaven. In the center, Christ raises His right arm. The Virgin Mary, who intercedes for souls, sits beside Him. In response to Christ's commanding gesture, the world below comes to life. On the left, tombs open and the dead—some skeletons, others in grave shrouds—rise toward heaven. To the right, the damned tumble or are dragged into hell. Hell is filled with demons and is ruled over by Minos, the mythical king of Crete who imprisoned a monster known as the Minotaur. A large snake coils around Minos. The depiction of hell is based on *The Divine Comedy* (1321), a famous poem by the Florentine writer Dante Alighieri. Michelangelo is supposed to have known the lengthy poem by heart. See **Religion** (picture: Salvation from eternal punishment).

The Last Judgment caused great controversy, and Michelangelo was very disturbed by the reaction to his work. Some critics objected that Christ was shown inap-

propriately. The fresco was bitterly criticized for its display of nudity. In fact, draperies were later added to many of the figures by one of Michelangelo's followers. During the early 1990's, when the fresco was cleaned and repaired, restorers removed some of these draperies.

Later years. The small amount of sculpture in Michelangelo's later years includes works to complete old commissions and two unfinished Pietà groups. He created both Pietàs for his own satisfaction and not for a patron. One of the Pietàs is now in the Cathedral of Florence and is called the Florentine *Pietà* (1555). It was meant for Michelangelo's own tomb. It is designed as a massive pyramid, with Christ's body slumping down on the ground.

In the other Pietà, known as the Rondanini *Pietà* (1564), now in Milan, the marble limbs are reduced to a ghostlike thinness. The bodies seem to lack substance, while the material of the stone is emphasized by the hacking chisel marks left on the unfinished surface. Because of this technique, many modern sculptors, including Henry Moore, admire this work above all others Michelangelo produced.

Michelangelo devoted much time after 1546 to architecture and poetry. In 1546, Pope Paul III appointed him supervising architect of St. Peter's Basilica, one of Julius II's unfinished projects. Michelangelo worked on the church without salary. By the time he died in 1564, construction had reached the lower part of the dome, which was finished by another architect (see **Rome** [picture: An air view of Rome]).

After 1538, Michelangelo planned a square for the Civic Center of Rome and the buildings facing it. The square is shaped like a trapezoid, a four-sided figure with two parallel sides of unequal length. The square and the oval design at its center symbolize Rome as the center of the world.

Michelangelo's last paintings, which were finished when he was 75 years old, were frescoes in the Pauline Chapel in the Vatican. These paintings show *The Conversion of Saint Paul* (1545) and *The Crucifixion of Saint Peter* (1550). Although they are large, complicated designs like the Sistine Chapel paintings, they are graver, more still and inward. Michelangelo became deeply religious in his last years, during which he made devotional drawings comparable to the Rondanini *Pietà*. He also wrote some of his finest poetry during his old age.

Michelson, *MY kuhl suhn,* **Albert Abraham** (1852-1931), was the first American citizen to win a Nobel Prize in science. He won the 1907 Nobel Prize in physics for his design of precise optical instruments and for the accurate measurements he obtained with them.

Michelson was born in Strzelno, Poland (then in the domain of Prussia), near Inowrocław. His family immigrated to the United States when he was 2. In 1873, Michelson graduated from the U.S. Naval Academy.

In 1880, while studying in Germany, Michelson designed an instrument to measure the speed of the earth through the *ether.* At that time, scientists believed that all space was filled with a stationary substance, which they called ether. They thought that light must travel in such a substance as ether to travel through space. Michelson's instrument, now known as the *Michelson interferometer,* compares the speed of a light beam moving in one direction with that of a beam moving at a right angle to it. By measuring the interference of the two light beams, Michelson believed he could find the velocity of the earth through the ether. He determined from the interference pattern actually produced that the speed of the earth in relation to the ether was zero. In 1887, Michelson refined this experiment with the aid of Edward Morley, an American chemist and physicist. The result was the same as before. Michelson and Morley's experiment helped destroy the ether theory (see **Ether**).

Michelson resigned his naval commission in 1881. He taught physics at the University of Chicago for most of his career. Richard L. Hilt

Michener, *MIHCH uh nuhr,* **James Albert** (1907-1997), an American author, won the 1948 Pulitzer Prize for fiction for his collection of stories, *Tales of the South Pacific* (1947). The book describes the life of United States servicemen among people of the Solomon Islands during World War II (1939-1945). Joshua Logan, Richard Rodgers, and Oscar Hammerstein II based their musical comedy *South Pacific* (1949) on stories in Michener's collection.

Michener's novels include *The Fires of Spring* (1949), *The Bridges at Toko-ri* (1953), *Sayonara* (1954), *Hawaii* (1960), *The Source* (1965), *Centennial* (1974), *Chesapeake* (1978), *The Covenant* (1980), *Texas* (1985), *Alaska* (1988), *Caribbean* (1989), *The Novel* (1991), and *Miracle in Seville* (1995). He also wrote on current events and Asian art. Michener wrote an autobiography, *The World Is My Home* (1991). He was born in New York City.

Samuel Chase Coale

Michener, *MIHCH uh nuhr,* **Roland** (1900-1991), was governor general of Canada from 1967 to 1974. In 1967, he became the first governor general to give the Order of Canada, the nation's highest civilian honor. He also awarded the first Order of Military Merit in 1972. He helped promote physical fitness by jogging about 2 miles (3.2 kilometers) a day. He also encouraged all Canadians to learn both English and French.

Daniel Roland Michener was born in Lacombe, Alberta. He received a bachelor's degree from the University of Alberta and a law degree from Oxford University in England.

Michener served in the Ontario legislature from 1945 to 1948. He was elected to Canada's House of Commons in 1953 and became speaker in 1957. In 1964, he was appointed high commissioner to India and Canada's first ambassador to Nepal. Jacques Monet

Lake of the Clouds is surrounded by the thick forests of the Porcupine Mountains. The lake is in Michigan's Upper Peninsula, one of the two separate land areas that make up the state.

Michigan *The Wolverine State*

Michigan is an important industrial, farming, tourist, and mining state in the Great Lakes region of the United States. It is one of the nation's leading manufacturing states. Michigan leads in the manufacture of automobiles. Detroit, Michigan's largest city, is called the *Automobile Capital of the World* and the *Motor City.* The Detroit area produces more cars and trucks than any other part of the nation. Flint and Lansing also are important automaking centers. Michigan is a leading manufacturer of machinery, metal products, chemicals, and food products. Service industries, such as health care and retail trade, employ many people in the state.

Michigan touches four of the five Great Lakes—Erie, Huron, Michigan, and Superior. The state's 3,288-mile (5,292-kilometer) shoreline is longer than that of any other state except Alaska. Michigan consists of two separate land areas, called the Upper Peninsula and the Lower Peninsula. The two peninsulas are connected by the Mackinac Bridge, which spans 5 miles (8 kilometers) across the Straits of Mackinac.

Most farming in Michigan takes place in the southern half of the Lower Peninsula. Extensive areas of the Lower Peninsula near the shore of Lake Michigan are excellent for fruit growing. Michigan is among the leading states in growing apples, cherries, and many other fruits.

Michigan is one of the leading tourist states. About 22 million people visit the state each year. Both the Upper and Lower peninsulas offer resort and recreation facilities, and scenic beauty. In addition to the Great Lakes, Michigan has more than 11,000 smaller lakes. Forests cover over half the state. Michigan offers excellent hunting and fishing opportunities for sport enthusiasts.

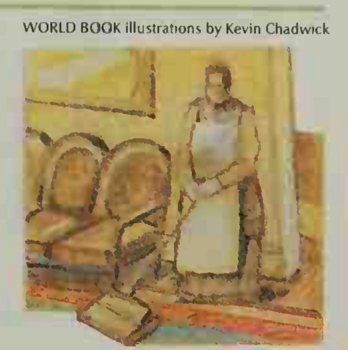
Michigan is second only to Minnesota in iron ore production. Iron ore is mined in the Upper Peninsula. The state's other chief mineral products, natural gas and petroleum, are found in the northern part of the Lower Peninsula. Michigan is also an important producer of sand and gravel, crushed stone, and salt.

The contributors of this article are Justin L. Kestenbaum, Former Professor of History at Michigan State University; and Harold A. Winters, Professor of Geography at Michigan State University.

Interesting facts about Michigan

The world's first agricultural college was Michigan State University. It was founded in 1855 as Michigan Agricultural College. Michigan State is also the oldest U.S. land-grant college.

Mackinac Bridge, designed by David B. Steinman and completed in 1957, connects Michigan's Upper and Lower peninsulas. Michigan is the only state in the continental United States to have such large sections entirely separated by water.



Battle Creek is called the *Cereal Bowl of America.* John H. Kellogg's interest in health foods for patients at the Battle Creek Sanitarium stimulated the ready-to-eat breakfast food industry. Charles W. Post and W. K. Kellogg, John's brother, made the cereal industry a successful commercial venture in the early 1900's. Today, Battle Creek produces more breakfast cereal than any other city in the world.

Cereal Bowl of America

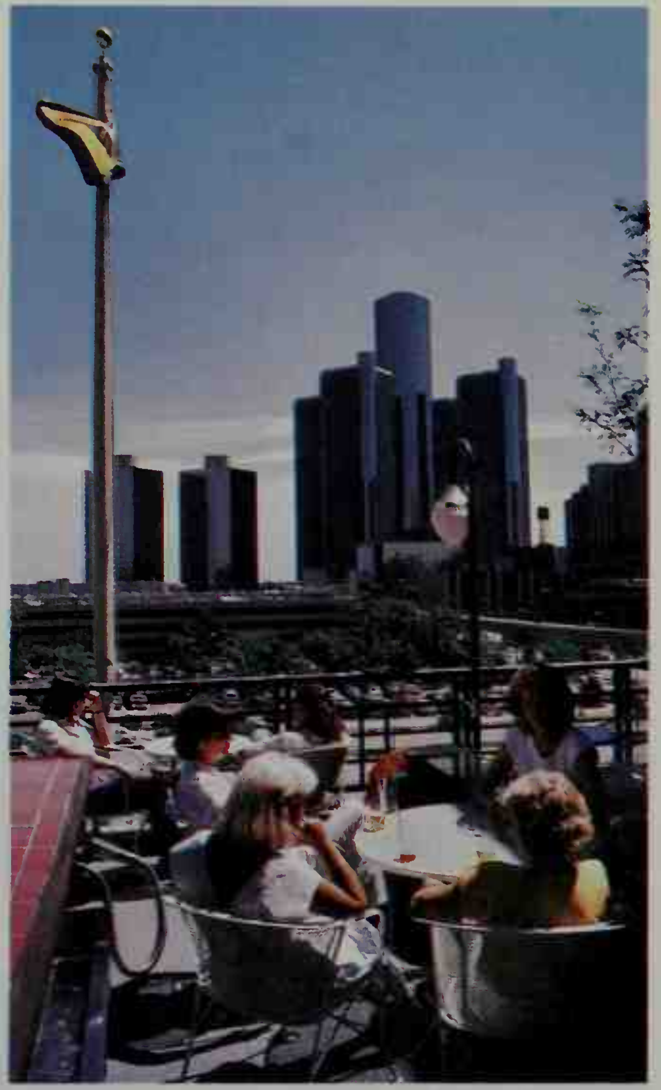
WORLD BOOK illustrations by Kevin Chadwick

The first practical carpet sweeper was invented by M. R. Bissell in Grand Rapids in 1876. The Bissell factory, still located there, is the world's largest manufacturer of carpet sweepers.

First carpet sweepers

The first traffic lines to designate lanes were painted near Trenton in 1911. Edward N. Hines, Wayne County road commissioner, proposed the lines. He called them "center line safety stripes."

The first person to observe digestion was William Beaumont, an Army doctor stationed at Fort Mackinac. He treated Alexis St. Martin, a fur trader who was shot by accident in the abdomen on Mackinac Island in 1822. Beaumont tried patiently to close the wound, but it never healed. Despite his injury, St. Martin lived to the age of 76. He was known as "the man with a window in his stomach." Through this "window," Beaumont gathered information that has proved to be accurate.



Ford Motor Company

Robots weld car bodies at a manufacturing plant in Wixom. Michigan ranks as the leading U.S. automaking state.

French explorers of the early 1600's were the first Europeans to visit what is now Michigan. France controlled the region for nearly 150 years, but did little to develop it. Britain gained control of the Michigan region after defeating France in the French and Indian Wars (1689-1763). In 1787, after the Revolutionary War in America, the area became part of the Northwest Territory of the United States. In 1805, Congress established the Territory of Michigan. In 1837, Michigan became the 26th state.

The name *Michigan* comes from the Chippewa Indian word *Michigama,* which means *great,* or *large,* lake. Michigan is nicknamed the *Wolverine State* because the early fur traders brought valuable wolverine pelts to trading posts in the region. The state is also known as the *Water Wonderland,* because of its many beautiful lakes and streams. Including its share of the Great Lakes, Michigan has more fresh water than any other state. The Upper Peninsula is sometimes called the *Land of Hiawatha* because that part of the state is described in Henry Wadsworth Longfellow's poem *The Song of Hiawatha* (1855).

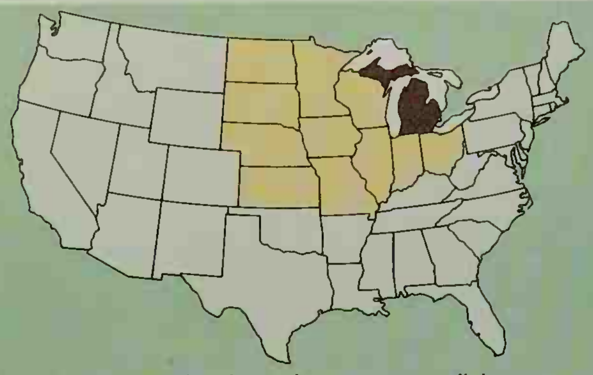
People relax in an outdoor cafe overlooking downtown Detroit. The modern Renaissance Center, one of the largest renewal projects in United States history, rises in the background.

Michigan in brief

Symbols of Michigan

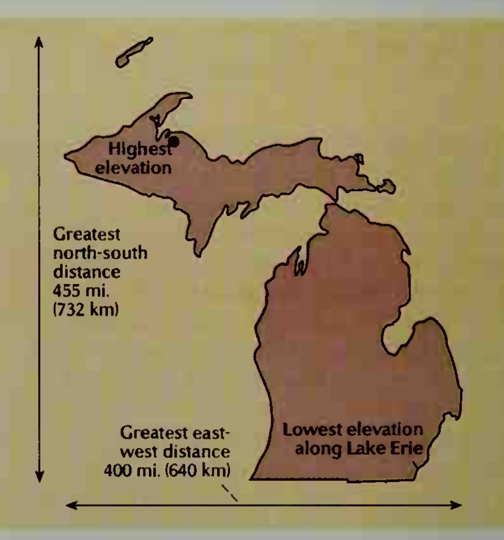


The state flag, adopted in 1911, bears a version of the state seal. The seal was adopted in 1835. A bald eagle, the national bird, symbolizes the superior authority and jurisdiction of the United States over state governments. An elk and a moose, representing Michigan, support a shield with the Latin word *Tuebor,* which means *I Will Defend.*

State flag

State seal

Michigan (brown) ranks 23rd in size among all the states and 7th in size among the Midwestern States (yellow).



The State Capitol is in Lansing, Michigan's capital since 1847. Detroit served as capital from 1837 to 1847.

General information

Statehood: Jan. 26, 1837, the 26th state.
State abbreviations: Mich. (traditional); MI (postal).
State motto: *Si Quaeris Peninsulam Amoenam, Circumspice* (If You Seek a Pleasant Peninsula, Look About You).
State song: (unofficial): "Michigan, My Michigan." Words by Douglas M. Malloch.

Land and climate

Area: 58,513 sq. mi. (151,548 km²), including 1,704 sq. mi. (4,412 km²) of inland water but excluding 38,192 sq. mi. (98,917 km²) of Great Lakes water.
Elevation: *Highest*—Mount Curwood, 1,980 ft. (604 m) above sea level. *Lowest*—572 ft. (174 m) above sea level along Lake Erie.
Record high temperature: 112 °F (44 °C) at Mio on July 13, 1936.
Record low temperature: −51 °F (−46 °C) at Vanderbilt on Feb. 9, 1934.
Average July temperature: 69 °F (21 °C).
Average January temperature: 20 °F (−7 °C).
Average yearly precipitation: 32 in. (81 cm).

Important dates

- **1620** Étienne Brulé of France explored the Upper Peninsula of Michigan.
- **1668** Father Jacques Marquette founded Michigan's first permanent settlement at Sault Ste. Marie.
- **1701** Antoine Cadillac founded what is now Detroit.
- **1837** Michigan became the 26th state on January 26.

For information on the economy, write to: Library of Michigan, Public Services, 717 W. Allegan Street, P.O. Box 30007, Lansing, MI 48909-7507.
The state's official Web site at www.state.mi.us also provides a gateway to much information on Michigan's economy, government, and history.

1899 Ransom E. Olds established Michigan's first automobile factory in Detroit.
1935 Michigan workers formed the United Automobile Workers union.
1964 A new state constitution went into effect.
1972 Michigan established a state lottery.
1992 The Michigan Scenic Rivers Act protected many areas along rivers in the state from development.

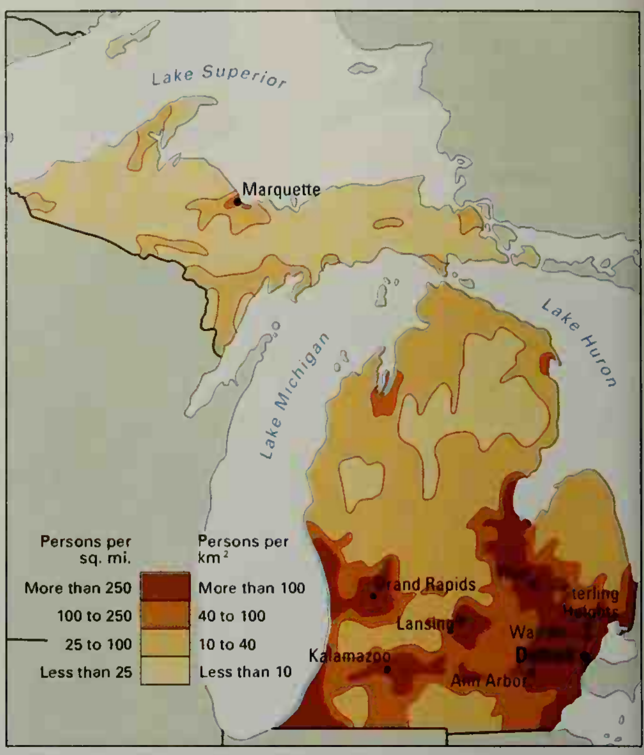
People

Population. The 2000 United States census reported that Michigan had 9,938,444 people. The population had increased about 7 percent over the 1990 figure, 9,295,297. According to the 2000 census, Michigan ranks 8th in population among the 50 states.

Over 80 percent of the people of Michigan make their homes in one of the state's nine metropolitan areas (see Metropolitan area). These are Ann Arbor, Benton Harbor, Detroit, Flint, Grand Rapids-Muskegon-Holland, Jackson, Kalamazoo-Battle Creek, Lansing-East Lansing, and Saginaw-Bay City-Midland. For the populations of these metropolitan areas, see the *Index* to the political map of Michigan. The majority of the people in the state live in the Lower Peninsula. Only about 300,000 people, or about 3 percent, live in Michigan's Upper Peninsula.

Detroit is Michigan's largest city, and the 10th largest city in the United States. Other large cities in Michigan, in order of population, are Grand Rapids, Warren, Flint, Sterling Heights, Lansing, Ann Arbor, Livonia, Dearborn, Westland, Farmington Hills, Troy, and Kalamazoo. All of these cities have populations of more than 75,000, and all of them are in the Lower Peninsula. The largest city in the Upper Peninsula is Marquette. It has a population of about 20,000 people.

Michigan has a population density of about 170 per square mile (66 per square kilometer). The Lower Peninsula is densely settled, with about 230 persons per square mile (89 per square kilometer). Figures for the Upper Peninsula are much lower—about 20 per square mile (8 per square kilometer).



About 96 out of 100 people in Michigan were born in the United States. Of the more than 350,000 people from other countries who live in the state, the largest group came from Canada.

About 14 percent of Michigan's people are African Americans. Other large population groups in the state include people of German, Irish, English, Polish, French, and Dutch descent.

Schools. Roman Catholic missionaries who came to the Michigan region in the 1600's established schools for the Indians. In 1798, Father Gabriel Richard came to Detroit to serve as pastor of Ste. Anne's Roman Catholic Church. He established schools to provide regular classes and vocational training for Indian and white children.

Population density

Most of Michigan's people live in urban areas in the southern half of the Lower Peninsula—especially in and around Detroit. The Upper Peninsula is thinly settled.

WORLD BOOK map: based on U.S. Census Bureau data.

In 1809, the territorial legislature passed Michigan's first school law. The law provided for school districts, school taxes, and the building of public schools. In 1827, the legislature provided for community schools maintained by townships. After Michigan entered the Union in 1837, the Legislature approved a statewide system of public education, including a university. The new state Constitution provided for the appointment of a superintendent of public instruction to administer the public school system. The Michigan superintendent of public instruction was the first such administrator in the nation.

Eastern Michigan University, established in 1849, was

University of Michigan

College football is a popular spectator sport in Michigan. The Wolverines of the University of Michigan play their home games at Michigan Stadium in Ann Arbor, *shown here,* which seats more than 100,000 people.

the first state teachers college west of New York. Michigan State University, founded in 1855, was the first state school to offer agriculture courses for credit. In 1879, the University of Michigan became one of the first state universities to establish a *chair* (special teaching position) in education.

The State Board of Education directs Michigan's public school system. The board consists of eight elected members. It appoints the superintendent of public instruction, who administers the public school system. The board directs the Michigan Department of Education, which carries out the board's duties. Children in Michigan must attend school from ages 6 through 15. For the number of students and teachers in Michigan, see **Education** (table).

Libraries. The Library of Michigan—the state library—was founded in Detroit in 1828, when many settlers were moving into the Michigan Territory. Today, the library has collections of state and federal documents, and collections dealing with Michigan family histories and with law. Michigan also has library organizations that share resources and services among libraries.

The William L. Clements Library at the University of Michigan has a famous collection on early America. The Gerald R. Ford Library in Ann Arbor contains the papers of the 38th U.S. president. The Detroit Public Library has the Burton Historical Collection. This collection contains reference works on Michigan and the Great Lakes area. The Walter P. Reuther Library of Wayne State University in Detroit has material related to the history of labor, Michigan, and the Detroit area.

Museums. The Detroit Institute of Arts was established in 1885. Its collection of paintings and sculptures includes murals by the famous Mexican artist Diego Rivera. The Detroit Historical Museum contains exhibits on the history of Detroit and Michigan. The Charles H. Wright Museum of African American History in Detroit has displays related to the history of blacks in the United States. Greenfield Village, in Dearborn, is an indoor-outdoor museum complex. Its exhibits deal with American industrial history and life in the 1700's and 1800's.

The Michigan Historical Museum in Lansing tells the story of Michigan's past from prehistoric times to 1975. The Public Museum of Grand Rapids has natural history exhibits. The Gerald R. Ford Museum in Grand Rapids exhibits items relating to the former U.S. president. The Kingman Museum of Natural History in Battle Creek has exhibits of wildlife, prehistoric mammals, and ancient relics. The Alfred P. Sloan, Jr., Museum in Flint has displays on transportation. Mackinac Island has seven museums. One features the instruments of William Beaumont, a surgeon who made discoveries about digestion.

© Ken Kaminsky

The Detroit Public Library has branches throughout the city. It features the Burton Historical Collection, a body of reference materials on Michigan and the Great Lakes region.

Visitor's guide

Michigan has year-round activities for people who enjoy sports and the outdoors. Thousands of lakes, along with many rivers and streams, attract swimmers, water skiers, fishing enthusiasts, and boaters. Thick forests and scenic woodlands appeal to hunters and campers. In winter, many people travel to Michigan for skiing, skating, snowmobiling, tobogganing, iceboat racing, and ice fishing. International ski-flying competitions are held in Ironwood at Copper Peak, one of the world's largest artificially created ski-flying hills. Sightseers are drawn to the many beautiful waterfalls as well as to dunes and the rugged "Copper Country" of the western Upper Peninsula.

One of Michigan's most popular annual events is the weeklong Tulip Festival, held each May in Holland. The people of the city dress in traditional Dutch costumes. The festival includes parades, dancing in wooden shoes, and ceremonial street washing.

Grand Sable Dunes at Pictured Rocks National Lakeshore near Munising

Places to visit

Following are brief descriptions of some of Michigan's many interesting places to visit:

Arboretums of Michigan have some of the country's finest collections of plants, shrubs, and trees. Leila Arboretum, in Battle Creek, is a landscaped park that has rare plants and a wildlife museum. Nichols Arboretum, in Ann Arbor, is a natural environment that has more than 600 species of trees and shrubs, including about 250 kinds of peonies.

Big Spring, or *Kitch-iti-kipi,* near Manistique, is a pool fed by 16,000 gallons (61,000 liters) of water per minute erupting from its depths. The pool is 45 feet (14 meters) deep and 200 feet (61 meters) across. The water is so clear that visitors can watch large brown trout swimming in the pool.

Detroit produces more cars and trucks than any other city in the nation. It is one of the largest cities in the United States and a leading port. The city's cultural community includes libraries, museums, and the Museum of African American History. Greektown is a popular tourist attraction. See **Detroit**.

Fort Michilimackinac, in Mackinaw City, is a reconstruction of the fort built in the 1700's. Buildings include the home of British commander Robert Rogers, and Ste. Anne's Jesuit church. Nearby historic attractions include Historic Mill Creek, which has a water-powered sawmill and sawpit.

Greenfield Village, in Dearborn, is a collection of historic buildings and landmarks restored by Henry Ford. It includes buildings made famous by Abraham Lincoln, Thomas Edison, William H. McGuffey, and Stephen Foster. The Henry Ford Museum stands next to Greenfield Village.

Kellogg Bird Sanctuary, on Gull Lake near Battle Creek, is a 100-acre (40-hectare) refuge for ducks, geese, pheasants, swans, and other wild birds.

Mackinac Island is a famous resort island in the Straits of Mackinac, at the northern end of Michigan's Lower Peninsula. Historic Fort Mackinac stands on the island. No automobiles are permitted on the island. See **Mackinac Island**.

National Ski Hall of Fame, in Ishpeming, pays tribute to famous United States skiers, skiing events, and people who have made outstanding contributions to the sport.

Pictured Rocks National Lakeshore, between Munising and Grand Marais, on Lake Superior, has beautifully colored cliffs that have been carved into spectacular shapes by the action of waves. The Grand Sable Dunes are also located at Pictured Rocks.

Sleeping Bear Dunes National Lakeshore, near Empire on Lake Michigan, features massive coastal sand dunes, the tallest of which rises about 465 feet (142 meters) above the lake.

Soo Canals, at Sault Ste. Marie, permit ships to travel between Lake Huron and Lake Superior through huge locks. See **Soo Canals**.

Tahquamenon Falls, near Newberry, are among the most beautiful sights of the Upper Peninsula. Henry Wadsworth Longfellow wrote about both the upper and lower falls of the Tahquamenon River in his poem *The Song of Hiawatha* (1855).

Windmill Island Municipal Park in Holland features the only authentic, operating Dutch windmill in the United States. Visitors may purchase flour that has been ground at the windmill.

National forests and parks. Michigan has four national forests. The largest, Ottawa National Forest, lies in the western part of the Upper Peninsula. Hiawatha National Forest is in the central and eastern parts of the Upper Peninsula. Huron National Forest occupies much of the Au Sable River Basin of the eastern Lower Peninsula. Manistee National Forest covers most of the Manistee River Basin in the western Lower Peninsula. Michigan's only national park, Isle Royale, is in northwestern Lake Superior, about 20 miles (32 kilometers) from the mainland of Minnesota. It includes Isle Royale and about 200 nearby small islands. The park has one of the largest remaining herds of great-antlered moose in the United States. Isle Royale National Park is about 48 miles (77 kilometers) from the Upper Peninsula. See **Isle Royale National Park**.

State parks and forests. Michigan has 99 state parks and recreation areas, 6 state forests, and more than 170 roadside parks and rest areas. Michigan's park system has over 14,000 prepared campsites, more than any other state. The state also has about 70 organized winter-sport areas. For information on the state parks and other attractions, write to Travel Michigan, P.O. Box 30226, Lansing, MI 48909-7726.

Annual events

January-March
Tip-Up Town, U.S.A. in Houghton Lake (January); I-500 Snowmobile Race in Sault Ste. Marie (early February); Invitational Nordic Ski Race in Newberry (mid-March); North American Snowmobile Festival in Cadillac (early February).

April-July
Maple Syrup Festival in Shepherd and Vermontville (April); Blossomtime Festival in St. Joseph-Benton Harbor (early May); Highland Festival and Games in Alma (May); Grand Prix in Detroit (June); Bavarian Festival in Frankenmuth (June); Cereal Festival in Battle Creek (June); International Freedom Festival in Detroit (late June-early July); Lumbertown Music Festival in Muskegon (early July); National Cherry Festival in Traverse City (early July); Yacht Races at Mackinac Island from Chicago and Port Huron (July); Ann Arbor Art Fair (July).

August-September
Upper Peninsula State Fair in Escanaba (mid-August); Michigan State Fair in Detroit (late August); Mackinac Bridge Walk, from St. Ignace to Mackinaw City (Labor Day); Montreux/Detroit Jazz Festival (Labor Day weekend); Michigan Wine and Harvest Festival in Paw Paw and Kalamazoo (mid-September).

October-December
Fall color tours, statewide (mid-September through October); Red Flannel Festival in Cedar Springs (October); hunting season, parts of Upper and Lower peninsulas (October-November), statewide (November); Christmas at Greenfield Village in Dearborn (December).

Land and climate

Land regions. Michigan has two main land regions: (1) the Superior Upland and (2) the Great Lakes Plains.

The Superior Upland extends along Lake Superior and covers the western half of the Upper Peninsula. Much of the region is rugged, rising from about 600 to 1,980 feet (180 to 604 meters) above sea level. Michigan's highest hills are in this region. The Porcupine Mountains in extreme northwestern Michigan rise more than 1,000 feet (305 meters) from the shores of Lake Superior. Mount Curwood is the highest point in the state, 1,980 feet (604 meters) above sea level. Forests cover most of these hills. The Superior Upland has some of the nation's richest iron and copper deposits.

The Great Lakes Plains stretch along the Great Lakes from Wisconsin to Ohio. In Michigan, the region covers the eastern Upper Peninsula and the entire Lower Peninsula. In the Upper Peninsula, parts of the Great Lakes Plains are lowlands covered by swamps. A short growing season and poor soils make many parts of the area unsuitable for farming. The Great Lakes Plains are part of a large Midwestern land region called the *Interior Plains.*

Much of the Lower Peninsula is fairly level, but some parts are rolling and hilly. Parts of the north-central Lower Peninsula rises 1,200 to 1,400 feet (366 to 427 meters) above sea level. Many high bluffs and sand dunes border Lake Michigan. The state's lowest point, 572 feet (174 meters) above sea level, is along the shore of Lake Erie. Parts of the northern Lower Peninsula have sandy wastes, covered with jack pine trees, scrub, and stumps. The southern half of the Lower Peninsula has much good farmland.

Shoreline of Michigan is 3,288 miles (5,292 kilometers) long—more than that of any other state except Alaska. This includes 1,056 miles (1,699 kilometers) of island shoreline. Four Great Lakes border the state—Erie, Huron, Michigan, and Superior. No part of Michigan lies more than 85 miles (137 kilometers) from one of these lakes.

Bays along the Lower Peninsula include Grand Traverse and Little Traverse on Lake Michigan, and Saginaw on Lake Huron. The Upper Peninsula has Whitefish and Keweenaw bays on Lake Superior, and Big Bay de Noc on Lake Michigan. Green Bay touches the southern tip of the Upper Peninsula.

Islands. Michigan's largest island, Isle Royale, covers about 210 square miles (544 square kilometers) in Lake Superior. The Beaver and Manitou islands are in Lake Michigan. Bois Blanc, Mackinac, and Round islands are in Lake Huron, just east of the Straits of Mackinac. Drummond Island, also in Lake Huron, lies off the eastern tip of the Upper Peninsula. The small islands in the Detroit River include Belle Isle and Grosse Ile.

Rivers, waterfalls, and lakes. The chief rivers of the Upper Peninsula include the Escanaba, Manistique, Menominee, Ontonagon, Sturgeon, Tahquamenon, and Whitefish. Principal rivers in the Lower Peninsula are the Au Sable, Clinton, Grand, Huron, Kalamazoo, Manistee, Muskegon, Raisin, Saginaw, and St. Joseph. The Grand River, 260 miles (418 kilometers) long, is the longest in the state. The Detroit, St. Clair, and St. Marys rivers are important for commerce. The Detroit River connects Lakes Erie and St. Clair. Lakes Huron and St. Clair are joined by the St. Clair. The St. Marys River connects Lakes Huron and Superior.

Michigan's Upper Peninsula has about 150 beautiful waterfalls. The best-known falls are the Upper and Lower Tahquamenon Falls on the Tahquamenon River. Other well-known waterfalls include the Agate, Bond, Laughing Whitefish, Miners, and Munising—all in the Upper Peninsula.

Michigan has more than 11,000 inland lakes. The largest is 31-square-mile (80-square-kilometer) Houghton Lake in the north-central Lower Peninsula. Most of the larger lakes are in the Lower Peninsula. They include Black, Burt, Charlevoix, Crystal, Higgins, Mullet, and Torch lakes. Lake Gogebic is the largest lake in the Upper Peninsula.

Plant and animal life. Forests cover more than half of Michigan. Much of the state's forest land is covered

Specially created for *The World Book Encyclopedia* by Rand McNally and World Book editors

James P. Rowan

Tahquamenon Falls, near Newberry, are located in the Great Lakes Plains region of Michigan's Upper Peninsula. The broad Upper Tahquamenon Falls is known as the *Little Niagara.*

by such hardwood trees as aspens, beeches, birches, maples, and oaks. Softwoods cover most of the remaining forest land. These include cedars, firs, hemlocks, pines, and spruces.

Bittersweet, clematis, grapes, moonseed, and several kinds of smilax grow wild in Michigan's thickest forests. Such shrubs as blackberry, currant, elder, gooseberry, raspberry, rose, and viburnum thrive in the more open forest areas. Ferns and mosses grow in the swamps, as do cranberries and lady's-slippers. Such flowers as the arbutus, mandrake, trillium, and violet bloom in late April to early May. Flowers that bloom later in the year include the daisy, iris, orange milkweed, rose, shooting star, and tiger lily. Other common flowers include the aster, chicory, goldenrod, and sunflower.

Michigan probably has more deer than any other state except Texas. Other common fur and game animals in Michigan include badgers, black bears, minks, muskrats, opossums, rabbits, raccoons, red foxes, skunks, squirrels, and weasels. Hundreds of kinds of birds live in the state. Game birds most prized by hunters include ducks, geese, grouse, and pheasants.

Fishes found in Michigan's lakes, rivers, and streams include bass, crappie, perch, pike, salmon, trout, and walleye. Smelt runs occur each spring in streams that empty into parts of Lake Huron and Lake Michigan. Other fishes common in Michigan's waters include alewives, catfish, and chubs. Carp, lake herring, and whitefish are common in the Great Lakes.

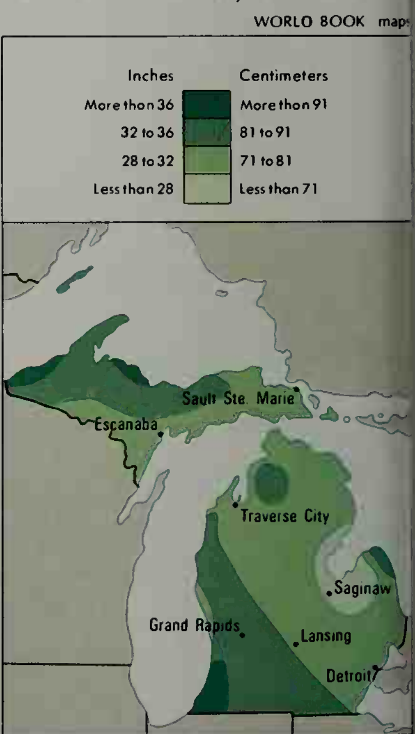
Traverse City
Saginaw
Grand Rapids
Lansing
Detroit

Average July temperatures



Michigan has warm summers. Temperatures decrease steadily from the south northward to the Upper Peninsula.

Average yearly precipitation

Michigan has a moist climate. Precipitation varies widely in the state. The Upper Peninsula receives heavy snowfalls.

WORLD BOOK maps

Climate. Michigan has a moist climate with cold winters and warm summers in the south and cool summers in the north. Winds from the Great Lakes bring much cloudiness. About 6 of every 10 days are partly cloudy in summer and about 7 of every 10 days in winter. Fall and winter are especially cloudy in the western Lower Peninsula and the eastern Upper Peninsula.

The Lower Peninsula is generally warmer than the Upper Peninsula. Average January temperatures range from 15 °F (−9 °C) in the western Upper Peninsula to 26 °F (−3 °C) in the southern Lower Peninsula. July temperatures average 65 °F (18 °C) in the eastern Upper Peninsula and 73 °F (23 °C) in the southern Lower Peninsula. Michigan's record low temperature, −51 °F (−46 °C), occurred in Vanderbilt on Feb. 9, 1934. Mio recorded the state's highest temperature, 112 °F (44 °C), on July 13, 1936. Air cooled by Lake Michigan in the spring usually prevents the budding of fruit trees until the danger of frosts has passed.

Michigan's yearly *precipitation* (rain, melted snow, and other forms of moisture) ranges from approximately 26 to 36 inches (66 to 91 centimeters). Annual snowfall in Michigan varies from less than 40 inches (102 centimeters) in the southeastern Lower Peninsula to more than 160 inches (406 centimeters) in the western Upper Peninsula. The state's record snowfall, 276 $\frac{1}{2}$ inches (702.3 centimeters), occurred at Houghton during the winter of 1949-1950.

Economy

Michigan has a blend of new and traditional industries. But the state's economy will be associated primarily with the automobile for a long time to come. Michigan ranks among the nation's leading manufacturing states. The production of transportation equipment ranks as the state's most important manufacturing industry. Detroit is Michigan's chief manufacturing center.

Service industries are increasingly important in the state. Included among these are high-technology companies that develop software and other products.

Important natural gas and petroleum deposits lie under Michigan's Lower Peninsula. Large iron ore deposits are found in the Upper Peninsula. The southern Lower Peninsula has the best farmland. Most of the state's livestock and crops are raised there. Fruit thrives along the Lake Michigan shoreline of the Lower Peninsula.

Michigan is a leading tourist state. Millions of people visit the state annually and contribute about $10 billion to the economy. Natural attractions, and resort and recreation areas, can be found in many parts of the Upper and Lower peninsulas.

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Manufacturing	27	994,900	18
Community, business, & personal services	19	1,620,000	30
Wholesale & retail trade	17	1,199,700	22
Finance, insurance, & real estate	15	371,500	7
Government	10	655,800	12
Transportation, communication, & utilities	7	204,900	4
Construction	4	274,500	5
Agriculture	1	122,800	2
Mining	†	14,100	†
Total	100	5,458,200	100

*GSP = gross state product, the total value of goods and services produced in a year.
†Less than one-half of 1 percent.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

Natural resources of Michigan include fertile soils, rich mineral deposits, widespread forests, plentiful water, and abundant plant and animal life. For information about the state's forests and plant and animal life, see the *Land and climate* section.

Soil. The Upper Peninsula of Michigan has soils that vary from fertile loams to areas of poor soils and infertile sands. The northern section of the Lower Peninsula has sandy and loamy soils similar to those of the Upper Peninsula of the state. A variety of soils cover former glacial lakebeds next to Saginaw Bay and along the shoreline of eastern Michigan. These glacial soils range from rich, dark brown or black loams and gray sands, to infertile soils that are shallow and poorly drained. The state's richest soils are in the southern half of the state.

Minerals. Michigan's Upper Peninsula has vast iron ore and copper deposits. Great stores of iron ore lie in the Marquette Range of the central Upper Peninsula. The Menominee Range in the southern Upper Peninsula, and the Gogebic Range in the western corner, also have enormous iron ore deposits. These iron deposits are part of one of the greatest known iron ore regions in the world. The Keweenaw Peninsula, which forms the northernmost tip of the Upper Peninsula, is one of the few sources of *native* (pure) copper in the world.

The Lower Peninsula holds valuable deposits of petroleum and natural gas. The largest of these deposits lies in the northern part of the Lower Peninsula. Other deposits are scattered across southern and central Michigan. Natural gas deposits are found in the northwestern part of the Lower Peninsula. The Lower Peninsula also has extensive deposits of salt. Brines containing calcium chloride and magnesium also occur in this region. Limestone and shale are widespread in the state. Gypsum deposits lie under part of the Lower Peninsula. Every county in Michigan has deposits of sand and gravel.

Service industries are those industries that provide services rather than produce goods. Taken together, they account for the largest portion of Michigan's *gross state product*—the total value of all goods and services produced in a state in a year. Michigan's service industries are concentrated in the metropolitan areas, especially in the Detroit area.

Community, business, and personal services form the leading service industry in Michigan. This group employs more people than any other economic activity in the state. Community, business, and personal services

include such activities as private health care, law firms, engineering and research companies, repair shops, and computer software firms. The suburban areas of Detroit have the largest concentration of private health care facilities in Michigan. Engineering and research companies receive much business from the automobile industry. These industries help Michigan rank among the nation's leaders in the size of its high-tech work force.

Wholesale and retail trade ranks next among Michigan's service industries in terms of the gross state product. In the wholesale trade sector, distributors of automobiles, automobile parts, groceries, and machinery are most important. The port of Detroit handles much of Michigan's international wholesale trade. Among the state's retail trade establishments, automobile dealerships, discount stores, grocery stores, and restaurants bring in the most income. Troy is the headquarters of Kmart, one of the nation's largest retailing companies.

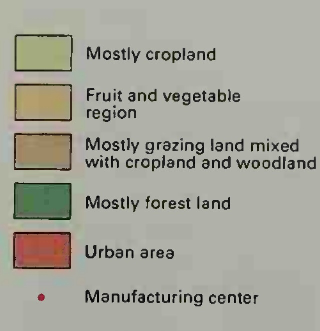
Michigan's third-ranking service industry is finance, insurance, and real estate. Detroit is the state's leading banking center. The insurance industry is especially important in Detroit and Lansing. Lansing is the home of Jackson National Life, one of the Midwest's largest insurance companies. Urban renewal projects and the growth of suburban areas have benefited Michigan's real estate companies.

Government ranks fourth among Michigan service industries. Government services include the operation of public schools and hospitals, and military establishments. The public school system is one of the major employers in the state. State government offices are based in Lansing. The federal and state government have branch offices in Detroit. Detroit's city government employs a large number of people.

© Linda Kelly-Hassett from Caryle Calvin

Workers test molten steel in a blast furnace in a Detroit steel plant. Michigan ranks among the leading states in producing iron ore and steel. Michigan factories also manufacture metal products.

Transportation, communication, and utilities form the fifth-ranking service industry in Michigan. Several railroad and trucking companies have large operations in Detroit. Television and telephone companies are the major parts of the communications industry in the state. The largest utility company in Michigan is Consumers Energy. More information about transportation and communication appears later in this section.



Manufacturing. Goods manufactured in Michigan have a *value added by manufacture* of about $90 billion a year. This figure represents the increase in value of raw materials after they become finished products.

Transportation equipment is Michigan's leading type of manufactured product. It provides about 40 percent of the state's manufacturing income. The transportation

Economy of Michigan

This map shows the economic uses of land in Michigan and where the leading farm and mineral products are produced. The major manufacturing centers are shown in red.

WORLD BOOK map

equipment industries employ about a fourth of all the industrial workers in the state.

Michigan is the leading manufacturer of automobiles in the nation. Detroit is known as *The Automobile Capital of the World* or *Motor City.* Other cities in Michigan that are important automobile-manufacturing centers include Dearborn, Flat Rock, Flint, Lansing, Orion Township, Pontiac, Sterling Heights, Warren, Wayne, and Wixom. Other vehicles produced in Michigan include full-sized and light trucks, vans and sport utility vehicles, airplanes, boats, and buses.

The production of machinery is the second most valuable manufacturing activity in Michigan in terms of value added by manufacture. Most of the state's machinery is made in the Detroit area. Bearings, chisels, dies, and valves, and other machine parts are the leading products. Other important kinds of machinery are computers, conveyors, engines, machine tools, and pumps.

Fabricated metal products are next in value added in Michigan. Products manufactured in the Detroit area account for about half of this total. Grand Rapids and Warren are important producers of fabricated metal products. Michigan's fabricated metal products include cutlery, hand tools, and hardware.

Chemicals are Michigan's fourth-ranking manufactured product. Pharmaceuticals are the most important type of chemical product made in the state. Factories that produce pharmaceuticals can be found in the Detroit area and several of Michigan's southwestern counties. Other important chemical products manufactured in Michigan include paint, resins, and soaps. Midland is the headquarters of Dow Chemical Company, one of the largest chemical companies in the world.

Food products rank fifth. Michigan is among the leading food-processing states. Detroit and Grand Rapids are the state's largest food-processing centers. Battle Creek, often called *The Cereal Bowl of America,* produces more breakfast cereal than any other city in the world. Fremont has the largest baby food plant in the United States. The state has important fruit and vegetable canneries and sugar refineries.

Other manufactured products made in Michigan include office furniture, paper products, primary metals, printed materials, and rubber and plastic products. The Grand Rapids area manufactures much of the office furniture made in Michigan. Kalamazoo is a center of the state's paper manufacturing industry. The manufacture of iron and steel is the most important portion of the primary metals industry. Aluminum production is also a significant part of that industry. The suburban part of the Detroit metropolitan area is the leading region for the production of primary metals in Michigan. Newspapers and business forms are the major types of printed materials produced in Michigan. Factories throughout the state manufacture rubber and plastic products, including rubber hoses and gaskets, plastic automotive parts, and plumbing supplies.

Michigan is among the leading states in the manufacture of sporting goods and athletic equipment. Such goods are produced, for example, in Muskegon, which has one of the nation's largest plants for making bowling alley equipment.

Agriculture. Farmland covers about a third of Michigan's land area. Michigan's best farmland is in the southern part of the state. Michigan has about 52,000 farms.

Crops provide about 60 percent of the total farm income. The state's leading field crops are soybeans, corn, hay, wheat, dry beans, sugar beets, and potatoes. Farmers raise corn, hay, and soybeans mostly as feed for livestock rather than as cash crops. Plants grown in greenhouses and nurseries, such as flowers and shrubbery, are also an important source of income. Michigan is the nation's second largest grower of Christmas trees.

The land along Lake Michigan in the Lower Peninsula is one of the most productive fruit-growing belts in North America. Michigan ranks among the leading states in raising apples, blueberries, cantaloupes, cherries, grapes, peaches, pears, plums, and strawberries. Fruit tree blossoms attract many bees in spring, and honey is an important by-product of the fruit industry.

Workers harvest cherries in an orchard in Leelanau County. They use a machine that shakes the trunk of the tree to make the cherries fall. Michigan is the leading cherry-growing area in North America.

Western Michigan has the best climate and soil for growing fruit. Most of the grapes are grown in the southwestern counties. Traverse City is famous for its cherries.

Most of Michigan's vegetable farming takes place in the southern half of the Lower Peninsula. Important vegetable crops raised in the state include asparagus, bell peppers, carrots, cauliflower, celery, cucumbers, onions, potatoes, pumpkins, snap beans, sweet corn, and tomatoes.

Livestock and livestock products provide about 40 percent of Michigan's farm income. Milk is the leading farm product. The state ranks among the leading producers of milk. Beef cattle and hogs are also important farm products. They are raised mainly in the Lower Peninsula.

Dairying is important throughout Michigan. Zeeland is a center of baby chick hatcheries. Ottawa County has large turkey farms, and chicken, duck, geese, and turkey hatcheries.

Mining. Natural gas, iron ore, and petroleum provide most of the state's mining income. The northern part of the Lower Peninsula has the largest natural gas fields in Michigan. Natural gas is piped to the state's urban areas, where it serves as fuel for heating buildings. Michigan must import natural gas from other states to fully meet its needs. Some of the imported natural gas is stored underground in depleted gas reservoirs.

Michigan ranks second among the states in the production of iron ore. Only Minnesota produces more iron ore. The Marquette area on the Upper Peninsula produces all of Michigan's iron ore. Almost all of the iron ore mined in the state is a low grade of ore called *taconite.* Heavy production of iron ore in Michigan during the early 1900's depleted most of the higher grades of ore. Today, Michigan produces about a fourth of the nation's iron ore. But the importance of iron ore mining has declined greatly in both Michigan and the United States as a whole since 1950.

Michigan has about 4,600 active oil wells. Petroleum production occurs in much of the Lower Peninsula but is heaviest in the northwestern part. Michigan petroleum production is not large enough to meet the total demand within the state.

Rogers City has one of the world's largest limestone quarries. Michigan leads the nation in the production of iron oxide pigments and magnesium compounds. The state ranks among the leaders in the production of gypsum, iodine, peat, and sand and gravel. Large deposits of copper lie in the western part of the Upper Peninsula. These deposits are expensive to mine. As a result, copper is mined in Michigan only when copper prices are high.

Fishing industry. Most of Michigan's fish catch is taken from the Great Lakes. The most valuable fishes include catfish, chubs, lake herring, lake trout, salmon, whitefish, and yellow perch. Every spring, workers in the commercial fishing industry take smelts from the state's rivers and streams.

Electric power. Plants that burn coal provide about 70 percent of Michigan's electric power. Nuclear plants provide most of the rest of the state's electric power. Hydroelectric plants and plants that burn natural gas or petroleum supply only a small amount of the power.

Transportation. American Indians and early pioneers in Michigan traveled in canoes along the waterways. The first roads followed Indian trails. The first highway in Michigan was built in the 1820's. It extended from Detroit across the Maumee River into Ohio. The Erie and Kalamazoo Railroad was completed in 1836. Horses pulled the railroad's first cars. In 1837, the Erie and Kalamazoo started to operate what was probably the first steam locomotive west of the Allegheny Mountains. By the mid-1800's, stagecoach routes connected Detroit with Chicago.

The state highway department was established in 1905. In 1908, Michigan became the first state to build a concrete highway—a stretch 1 mile (1.6 kilometers) long in Detroit.

In 1957, the Mackinac Bridge was completed across the Straits of Mackinac. This was the first bridge to connect the Upper and Lower peninsulas. The International Bridge, across the St. Marys River at Sault Ste. Marie, was completed in 1962. It links Michigan with Ontario. This 2-mile (3-kilometer) bridge replaced ferryboats that once carried people across the river. Other links between Michigan and Ontario include a Detroit-to-Windsor bridge, a Detroit-to-Windsor tunnel, and a Port Huron-to-Sarnia bridge.

Today, Michigan has about 120,000 miles (193,000 kilometers) of roads. Six major rail carriers provide freight service in the state. Passenger trains serve the major cities of the Lower Peninsula. Detroit Metropolitan Airport, Michigan's chief air terminal, is one of the world's busiest airports. Grand Rapids has the state's second busiest airport.

Ships from Michigan ports carry huge cargoes of coal, iron ore, stone, and manufactured goods across the Great Lakes and through the Great Lakes-St. Lawrence Seaway system to various ports and even to other countries. The Soo Canals rank among the busiest ship canals in the Western Hemisphere, even though ice closes the canals from early January to March. Rivers in Illinois link the Great Lakes system to the Mississippi River. By using the Mississippi River barge system, barges from Michigan can transport cargo as far south as the Gulf of Mexico.

Detroit is Michigan's largest and busiest port. Other major ports in the state include Calcite (near Rogers City), Escanaba, Marquette, St. Clair, and Stoneport. An automobile ferry service crosses Lake Michigan between Ludington and Manitowoc, Wisconsin. Ferries also serve the Manitou Islands, Beaver Island, Mackinac Island, Isle Royale, and several smaller islands.

Communication. Michigan's first regularly published newspaper, the *Detroit Gazette,* was started in 1817. Radio station WWJ in Detroit began broadcasting in 1920. WWJ and Pittsburgh's KDKA were the nation's first regular commercial radio stations. Michigan's first TV station, WWJ-TV, began operating in Detroit in 1947.

Michigan's publishers produce about 300 newspapers, about 50 of which are dailies. Daily newspapers with the largest circulations include the *Detroit Free Press, The Detroit News, The Flint Journal,* and *The Grand Rapids Press.* Michigan's publishers also produce about 200 periodicals. The state has about 300 radio stations, 45 television stations, and some 35 cable TV systems. Internet providers serve most communities.

Constitution. Michigan's present Constitution was adopted in 1963 and went into effect in 1964. Earlier constitutions were adopted in 1835, 1850, and 1908.

Constitutional *amendments* (changes) may be proposed in three ways. *Initiative amendments* are introduced by petitions signed by a specified number of voters. *Legislative amendments* are introduced by members of the state Legislature. Legislative amendments must be approved by two-thirds of the members of both houses of the Legislature. Amendments can also be proposed by *constitutional conventions.* Beginning in 1978, and every 16 years thereafter, the voters will decide whether to call a constitutional convention. All proposed amendments must be approved by a majority of the voters who cast ballots on the amendment.

Executive. The Constitution of 1963 increased the governor's term of office from two years to four years. Michigan's governor may serve no more than two terms. The Constitution also increased from two to four years the terms of the lieutenant governor, secretary of state, and attorney general. These officials may serve no more than two terms. Beginning in 1966, each party's candidates for governor and lieutenant governor began running for office as a team. Thus, voters in Michigan cast a single vote for the governor and lieutenant governor together.

The governor, with the consent of the state Senate, appoints various state officials who are not elected. These officials include the treasurer, members of boards and commissions, and department heads. Officials elected to eight-year terms include regents of the University of Michigan, trustees of Michigan State University, governors of Wayne State University, and members of the State Board of Education.

To run for governor, candidates of major political parties must be nominated by the people in a primary election. Candidates for other statewide elective offices are nominated at party conventions. A *recall* law gives the people the right to vote to remove from office any elected officials other than judges. A specified number of qualified voters must sign a petition in order to hold such a recall vote.

Legislature of Michigan consists of a 38-member Senate and a 110-member House of Representatives. State senators serve four-year terms and may serve no more than two terms. State representatives serve two-year terms and may serve no more than three terms. Legislative sessions begin on the second Wednesday of every January. The sessions adjourn on a date determined by a joint resolution of the two houses—usually December 30.

Courts. Michigan's highest court is the state Supreme Court. This court has seven justices, elected to eight-year terms. The justices elect one of their members to serve as chief justice.

Michigan also has a court of appeals. Seven judges are elected from each of four districts drawn according to population. Michigan has 57 circuits, each with its own circuit court. Circuit courts are the highest trial courts in the state. Each county in Michigan has a probate court and a district court. Five cities in southeastern Michigan have special municipal courts. All appeals, circuit, district, and probate court judges are elected to six-year terms.

The governors of Michigan

	Party	Term
Stevens T. Mason	Democratic	1837-1840
William Woodbridge	Whig	1840-1841
James W. Gordon	Whig	1841-1842
John S. Barry	Democratic	1842-1845
Alpheus Felch	Democratic	1846-1847
William L. Greenly	Democratic	1847
Epaphroditus Ransom	Democratic	1848-1849
John S. Barry	Democratic	1850
Robert McClelland	Democratic	1851-1853
Andrew Parsons	Democratic	1853-1854
Kinsley S. Bingham	Republican	1855-1858
Moses Wisner	Republican	1859-1860
Austin Blair	Republican	1861-1864
Henry H. Crapo	Republican	1865-1868
Henry P. Baldwin	Republican	1869-1872
John J. Bagley	Republican	1873-1876
Charles M. Croswell	Republican	1877-1880
David H. Jerome	Republican	1881-1882
Josiah W. Begole	Democratic and Greenback	1883-1884
Russell A. Alger	Republican	1885-1886
Cyrus G. Luce	Republican	1887-1890
Edwin B. Winans	Democratic	1891-1892
John T. Rich	Republican	1893-1896
Hazen S. Pingree	Republican	1897-1900
Aaron T. Bliss	Republican	1901-1904
Fred M. Warner	Republican	1905-1910
Chase S. Osborn	Republican	1911-1912
Woodbridge N. Ferris	Democratic	1913-1916
Albert E. Sleeper	Republican	1917-1920
Alexander J. Groesbeck	Republican	1921-1926
Fred W. Green	Republican	1927-1930
Wilber M. Brucker	Republican	1931-1932
William A. Comstock	Democratic	1933-1934
Frank D. Fitzgerald	Republican	1935-1936
Frank Murphy	Democratic	1937-1938
Frank D. Fitzgerald	Republican	1939
Luren D. Dickinson	Republican	1939-1940
Murray D. Van Wagoner	Democratic	1941-1942
Harry F. Kelly	Republican	1943-1946
Kim Sigler	Republican	1947-1948
G. Mennen Williams	Democratic	1949-1960
John B. Swainson	Democratic	1961-1962
George W. Romney	Republican	1963-1969
William G. Milliken	Republican	1969-1983
James Blanchard	Democratic	1983-1991
John Engler	Republican	1991-

Local government. The county is Michigan's chief unit of local government. The state has 83 counties, each of which is divided into townships. Each county has a county board of commissioners as its legislative body. The board consists of representatives from each part of the county. Other officers include the county clerk, county treasurer, prosecuting attorney, register of deeds, and sheriff.

The Constitution permits counties and cities to have *home rule* (self-government) to the extent that they may frame, adopt, and amend their own charters. However, these powers can be restricted by the Constitution and the Legislature. More than a hundred Michigan cities have the city-manager form of government. Most of the other cities in the state have the mayor-council form. Counties adopting a home rule charter may have a county executive as their chief administrative officer.

Revenue. Taxes account for about half of the state government's *general revenue* (income). About a

fourth of the general revenue comes from federal grants and programs. Other sources include government services and a state lottery. Important sources of tax revenue include personal and corporate income taxes, a general sales tax, and motor vehicle licensing fees.

Politics. The Republican Party is strongest in rural areas of Michigan. Democratic strength lies in the Upper Peninsula, and in Detroit and other urban areas.

Since the mid-1800's, Michigan has supported the Republican candidate for President far more often than it has supported the Democratic candidate. For the state's electoral votes and voting record in presidential elections, see **Electoral College** (table). Also since the mid-1800's, Michigan has supported the Republican candidate for governor far more often than it has supported the Democratic candidate.

Thomas Gennara

Michigan's House of Representatives meets in this chamber in Lansing, the state capital. State representatives serve two-year terms.

History

Indian days. About 15,000 Indians lived in the Michigan area when Europeans first arrived. Most of the tribes belonged to the Algonquian language group. They included the Chippewa and Menominee tribes in the Upper Peninsula, and the Miami, Ottawa, and Potawatomi tribes in the Lower Peninsula. The Wyandot, who settled around what is now Detroit, belonged to the Iroquois language group. Only about 3,000 Indians lived in the forests of the Upper Peninsula.

French exploration and settlement. Étienne Brulé of France explored the Upper Peninsula around 1620. He was probably the first white person to visit the Michigan region. Brulé was sent to the Michigan region from Quebec by Governor Samuel de Champlain of New France (Canada).

In 1634, Champlain sent another explorer, Jean Nicolet, to the region to search for a route to the Pacific Ocean. Nicolet traveled through the Straits of Mackinac and explored parts of the Upper Peninsula. In 1660, Father René Ménard, a Jesuit missionary, established a mission at Keweenaw Bay. In 1668, Father Jacques Marquette founded Michigan's first permanent settlement, at Sault Ste. Marie.

During the late 1600's, Father Marquette; Louis Jolliet; René-Robert Cavelier, Sieur de La Salle; and other Frenchmen explored much of the region. They mapped many of the lakes and rivers. By 1700, the French had built forts, missions, and trading posts at several places in both the Upper and Lower peninsulas. In 1701, Antoine de Lamothe Cadillac founded Fort Pontchartrain, which grew into the city of Detroit.

The Michigan region made little progress under the French. Only a few settlers established farms in the region, mostly along the Detroit River. The main French interests were to convert the Indians to Christianity and to develop a profitable fur trade. They also hoped to use the region as a passage to the west.

British control. During the late 1600's and the 1700's, France and Britain struggled to gain control of North America. They fought a series of wars, and the French were defeated in 1763. Britain won most of the French holdings in North America, including the Michigan region. See **French and Indian wars.**

In 1763, during Pontiac's War, Indians attacked the British at Fort Michilimackinac in Mackinaw City. The Indians, led by the Ottawa chief Pontiac, also attacked a number of other forts, killing many of the settlers. Indians attacked Detroit for about five months, but were finally turned away. In 1774, the British made Michigan part of the province of Quebec. The British were more interested in fur trading than in settling the region.

During the Revolutionary War in America (1775-1783), the British sent raiding parties of Indians and whites from Detroit to attack American settlements. Spain and Britain also fought each other during the Revolutionary War. In 1781, Spanish forces captured Fort St. Joseph in Niles and held it one day. The Revolutionary War ended in 1783, and the Michigan region eventually came under

the control of the United States. The British wanted to hold on to the valuable fur trade as long as possible. They did not surrender Detroit or Fort Mackinac to the United States until 1796.

Territorial period. In 1787, the Michigan region became part of the Northwest Territory—the first territory established by the United States government. In 1800, Congress created the Indiana Territory, which included part of Michigan. The Indiana Territory obtained the entire Michigan region in 1803. In 1805, Congress established the Territory of Michigan. The territory included the Lower Peninsula and a small section of the easternmost part of the Upper Peninsula.

During the War of 1812, the British captured Detroit and Fort Mackinac. American forces regained Detroit in 1813. The British returned Fort Mackinac to the United States in 1815, after the war ended.

The Erie Canal was completed in 1825. This canal linked the Great Lakes with the Atlantic Ocean and, in doing so, provided a transportation route between the eastern states and the western territories. Many settlers came to Michigan, especially from New York and New England.

In 1835, a convention drew up a state constitution. The people *ratified* (approved) the Constitution on Oct. 5, 1835, and elected 23-year-old Stevens T. Mason as their first state governor. But Congress delayed admitting Michigan to the Union because of a dispute between Michigan and Ohio. The dispute involved a strip of land near Toledo. Congress settled the question in 1836 by giving the 520-square-mile (1,347-square-kilometer) "Toledo Strip" to Ohio and the entire Upper Peninsula to Michigan.

Progress as a state. Michigan became the 26th state of the Union on Jan. 26, 1837. The western Upper Peninsula soon proved to be a source of many valuable minerals. In 1842, the state obtained Isle Royale and the Keweenaw Peninsula in a treaty with the Indians. Iron-ore mining began near Negaunee in 1845. Large numbers of miners and prospectors soon came to the Upper Peninsula. By the late 1840's, mining was prospering in the state. But the miners needed some way to ship the ore from western Michigan to the iron and steel centers along the Great Lakes. This need was one of the chief reasons for the construction of the Soo Canal, which was completed in 1855 (see **Soo Canals**).

The Republican Party was named in 1854 in Jackson. Delegates to a Michigan state convention met there on July 6, 1854. They were the first to formally adopt the name *Republican* (see Republican Party).

Michigan soldiers fought in the Union Army during the American Civil War (1861-1865). General George A. Custer, a famous Union officer, led the Michigan cavalry. On May 10, 1865, the Fourth Michigan Cavalry captured Jefferson Davis, president of the Confederacy, near Irwinville, Georgia.

After the Civil War, lumbering became an important industry in Michigan. The construction of sawmills aided the rapid development of manufacturing in the state. Michigan lumber was used in building many cities, towns, and farms of the Midwest. Michigan hardwood lumber helped develop the furniture industry, which started in Grand Rapids in the 1830's. By 1870, Michigan led the nation in lumber production.

From 1870 to 1900, Michigan's population more than doubled. Agriculture developed as settlers poured into Michigan and cleared the land. Michigan took the lead among the states in the support of public education. Railroads and steamship lines promoted Michigan resorts, and the state's tourist industry began to develop.

The early 1900's brought further industrial expansion. In 1899, Ransom E. Olds founded the Olds Motor Works in Detroit. By 1901, the factory was mass-producing Oldsmobiles. Henry Ford organized the Ford Motor Company in 1903. Detroit soon became the center of the nation's automobile industry. This new industry increased Michigan's population and its prosperity.

In 1914, Henry Ford announced that the Ford Motor Company would share its profits with its workers. Ford also established a minimum wage of $5 a day. At that time, most unskilled workers earned only $1 a day, and skilled workers earned $2.50.

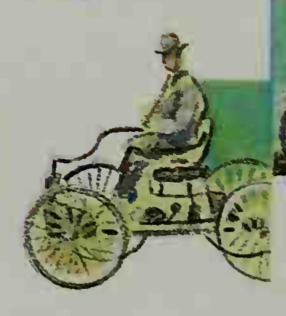
After the United States entered World War I in 1917, Michigan factories built trucks, armored vehicles, airplane engines, and other military products. The improvement of Michigan's highways during the 1920's contributed to the growth of the automobile industry and related businesses. By the late 1920's, tourism had become a leading source of income in the state.

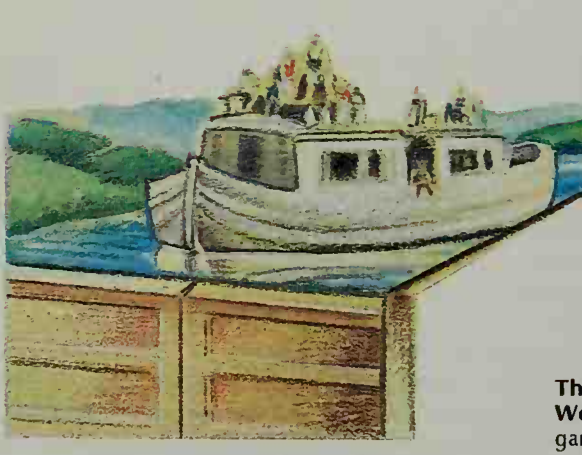
Depression and recovery. Michigan was hit hard by the Great Depression of the 1930's. Hundreds of thousands of workers lost their jobs. Federal measures to end the depression had important effects in Michigan. The state had more than a hundred Civilian Conserva-

Charles Symon Collection, Bentley Historical Library, University of Michigan

The Civilian Conservation Corps, a government employment program during the Great Depression of the 1930's, had more than 100 camps in Michigan. Young men in the program conserved and developed natural resources by planting trees, building dams, and fighting forest fires.

Historic Michigan





Detroit, Michigan's largest city, was founded as Fort Pontchartrain in 1701 by the French colonist Antoine Cadillac.

The Republican Party formally adopted its name at Jackson in 1854. The party began as a series of antislavery meetings throughout the North earlier that year.

Henry Ford built his first workable automobile in Detroit in 1896. Three years later, Ransom E. Olds established Michigan's first automobile factory in Detroit.

The Soo Canals at Sault Ste. Marie rank among the busiest ship canals in the Western Hemisphere, even though ice closes them from December to April. The first canal on the Michigan side was completed in 1855.

The United Automobile Workers organized in Michigan in 1935. By 1941, the union represented workers at all the major automobile companies.

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Michigan

1620? Étienne Brulé, a French explorer, visited what is now Michigan.

1668 Jacques Marquette founded Michigan's first permanent settlement at Sault Ste. Marie.

1701 Antoine Cadillac founded what is now Detroit.

1763 The British took possession of Michigan.

1783 The United States gained Michigan from the British after the Revolutionary War in America.

1787 Congress made Michigan part of the Northwest Territory.

1800 Michigan became part of the Indiana Territory.

1805 Congress created the Territory of Michigan.

1837 Michigan became the 26th state on January 26. Congress gave Michigan the entire Upper Peninsula.

1845 The Michigan iron mining industry began near Negaunee.

1854 The Republican Party was formally named at Jackson.

1855 The Soo Canal was completed.

1899 Ransom E. Olds established Michigan's first automobile factory in Detroit.

1914 The Ford Motor Company established a minimum daily wage of $5.

1935 Michigan workers formed the United Automobile Workers union.

1942-1945 Michigan's entire automobile industry converted to war production during World War II.

1957 The Mackinac Bridge was opened to traffic between Mackinaw City and St. Ignace.

1964 Michigan's new Constitution went into effect.

1967 Michigan's legislature adopted a state income tax.

1972 Michigan established a state lottery.

1992 The Michigan Scenic Rivers Act was passed by the U.S. Congress. It protects more than 500 miles (800 kilometers) along 14 Michigan rivers from development.

The Archives of Labor and Urban Affairs, Wayne State University

Mass production of tanks took place at this Chrysler Corporation factory in Detroit during World War II. After the United States entered the war in 1941, Michigan's entire automobile industry switched to manufacturing tanks, planes, and other war materials.

tion Corps (CCC) camps. In these camps, the government employed young men to work on conservation projects. The Works Progress Administration (WPA), later renamed the Work Projects Administration, employed about 500,000 people in Michigan to work on public works projects. Before and during the depression, copper mining in other states became less costly than in Michigan. It cost more to mine copper in Michigan because the ore lies so deep in the earth. Michigan's copper mining decreased, and more unemployment resulted in the Upper Peninsula.

In 1935, workers in the automobile industry organized the United Automobile Workers union. In December 1936, the union went on strike at the Fisher Body and Chevrolet plants in Flint. The strikers demanded a *closed shop* (an industry in which only union members can be hired). The union also called for *collective bargaining* (discussion of differences between company and union representatives). The Fisher and Chevrolet plant officials rejected the union's demands. The strikers then locked themselves inside the plants and fought off police attempts to remove them. The union received collective bargaining rights on Feb. 11, 1937, and the strike ended. After signing a contract with the Ford Motor Company in 1941, the United Automobile Workers represented the workers of all the large automobile companies, and won its chief demands. These demands included higher pay and recognition of the union as representative of the workers.

The mid-1900's. The United States entered World War II in December 1941. From 1942 until the war ended in 1945, Michigan's entire automobile industry switched to manufacturing war materials. The production of airplanes, ships, tanks, and other military equipment brought prosperity back to the state.

G. Mennen Williams, a Democrat, served as governor of Michigan from 1949 to 1960. He helped revive two-party politics in Michigan. Michigan's prosperity continued during his terms in office. Millions of Americans bought new cars and other products that were made in Michigan. The state's mining industry began to recover. In 1955, a new copper mine opened near Ontonagon. Iron-mining companies in Michigan's Upper Peninsula developed new methods of recovering iron from nonmagnetic ore and new ways of processing ore for shipment to steel plants. In 1957, the Mackinac Bridge was completed, linking the Upper and Lower peninsulas.

The state faced financial problems during the late 1950's and early 1960's. A nationwide recession caused a slump in Michigan automobile sales and production. As a result, other business activities in the state also slowed down. Michigan's financial picture brightened as the nation began to prosper again during the 1960's, and purchases of automobiles and other Michigan products increased.

In 1961, Michigan voters authorized a constitutional convention to revise the outdated state constitution, which had been adopted in 1908. A new constitution was submitted to the voters in 1962. They approved the constitution in 1963, and it went into effect in 1964.

George W. Romney, a Michigan businessman, served as the state's governor from 1963 to 1969. Romney, a Republican, had played a leading role in the constitutional convention. As governor, he fought for passage of the new constitution. Romney's administration modernized the state tax structure. New taxes, including a state income tax adopted in 1967, enabled Michigan to increase spending for education, mental health facilities, welfare programs, and other government services. In 1972, Michigan established a state lottery to help raise additional money.

In July 1967, an eight-day riot broke out in a predominantly black section of Detroit. Rioters burned buildings and looted stores. Forty-three people were killed, and about $45 million worth of property was damaged or destroyed.

In 1973, President Richard M. Nixon appointed Congressman Gerald R. Ford of Michigan to succeed Vice President Spiro T. Agnew, who had resigned. Ford became the 38th President in 1974, when Nixon resigned

because of his involvement in the Watergate political scandal.

Recent developments. Nationwide recessions during the early 1970's and the early 1980's contributed to slumps in the automobile industry, and unemployment in Michigan rose sharply. By 1980, Michigan had the highest unemployment rate of any state.

A serious financial crisis in the early 1980's forced the state government to cut funding for education, mental health services, welfare programs, and other services. By late 1983, improved automobile sales reduced the state's unemployment, and a temporary increase in the income tax enabled the state to restore program cuts.

In the 1990's, the production of transportation equipment remained the most important manufacturing activity in the state. Michigan continues to lead the nation in automobile production. But Michigan leaders are working to attract new industries to reduce the state's dependence on the automobile industry.

Michigan, University of, is a state-controlled coeducational university. The main campus is in Ann Arbor, and there are branch campuses in Dearborn and Flint. The Ann Arbor campus has colleges of architecture and urban planning, art, business administration, dentistry, education, engineering, law, liberal arts, library science, medicine, music, natural resources, nursing, pharmacy, public health, social work, and graduate studies. The Dearborn campus has five schools and colleges and the Flint campus has three.

The University of Michigan is a major research university. Its medical center, an 82-acre (33-hectare) complex of patient care, teaching, and research facilities, is one of the world's largest. Other research facilities include an institute for social research and a space physics research laboratory. Michigan's library, with $6\frac{1}{2}$ million

volumes, ranks as one of the largest academic libraries in the United States. The University of Michigan was founded in 1817.

Critically reviewed by the University of Michigan

Michigan State University is a state-supported coeducational school in East Lansing, Michigan. It is one of the largest single-campus institutions of higher education in the United States. Michigan State has colleges of agriculture and natural resources, arts and letters, business, communication arts and sciences, education, engineering, human ecology, human medicine, natural science, nursing, osteopathic medicine, social science, and veterinary medicine. It also has a graduate school. Michigan State also offers programs in lifelong education, international studies, and urban affairs. It grants bachelor's, master's, and doctor's degrees.

The school was founded in 1855 as Michigan Agricultural College. It served as a model for the land-grant colleges and universities founded later in the United States. The university was the first state school to offer courses in agriculture for credit. It took its present name in 1955.

Mickey Mouse. See **Disney, Walt** (with picture).

Micmac Indians, *MIHK mak,* are a tribe of eastern Canada. Their name is sometimes spelled *Mi'kmaq.* The tribe belongs to the Algonquian language family. About 12,000 Micmac live on reservations in New Brunswick, Nova Scotia, Prince Edward Island, and Quebec. Scattered communities also inhabit northern Maine. Large numbers of Micmac work in various cities but maintain close ties with family members on the reservation.

The Micmac once fished and gathered clams, mussels, and bird eggs from spring to fall. They hunted bears, moose, and small game during the winter. The Micmac used birchbark canoes for summer travel, and wooden toboggans and snowshoes in winter. They lived in tepees that they covered with animal skins or birchbark. The Micmac had many legends about a giant called Glooscap, who shaped their mountains and coastal landscape.

A few related families usually camped together in bands. Many bands, such as the Bear River band and the Red Bank band, were named after the area where they once lived. A chief called a *sagamore* led each band. He provided his followers with canoes, hunting dogs, and weapons in exchange for fish, game, and pelts.

In the early 1500's, the Micmac traded with French, Portuguese, and Spanish fishermen who visited Canada. When Jacques Cartier, a French explorer, came to Canada in 1534, the Indians traded their furs for beads and knives. Over many decades, the Micmac and the French joined in unsuccessful attempts to keep the British out of Canada. By the early 1800's, the British had control of most of the land occupied by the Micmac. The Indians retreated to remote sections of their land as the British founded settlements along the Atlantic coast. The Micmac came under the authority of the Canadian government in 1867. Micmac in the United States began campaigning for federal tribal recognition in the 1980's.

Microbiology, *MY kroh by AHL uh jee,* is the study of microscopic organisms. These organisms are sometimes called *microbes.* They include algae, bacteria, molds, protozoans, viruses, and yeasts. Microbiologists also study such tiny infectious particles as *prions, viroids,* and *plasmids.*

Many biologists specialize in the study of certain kinds of microorganisms. For example, *bacteriologists* work with bacteria, *mycologists* are concerned with fungi, and *virologists* study viruses.

Microorganisms. Nearly all microorganisms measure less than $\frac{4}{1,000}$ inch (0.1 millimeter) across. Many microorganisms must be studied with microscopes that magnify objects at least 1,000 times. Most viruses, plasmids, prions, and viroids are so tiny that they can be seen only with electron microscopes that magnify many thousands of times.

Viruses are called *acellular* microorganisms because they do not have true cell structures. All other microorganisms are *cellular.* They have cell membranes, cytoplasm, and either a nucleus or a nucleoid. Bacteria are the smallest single-celled organisms. The smallest bacteria may be as small as $\frac{4}{10}$ of a *micrometer* (a micrometer is $\frac{1}{25,400}$ inch, or .001 millimeter). About 10,000 small viruses could be packed into a cell the size of one of these bacteria. Over a billion of these tiny cells could be packed into one of the largest *microbial* cells—the cells of a certain algae.

Fields of microbiology. Many microbiologists study the relationships between microbes and human beings, animals, and plants. Medical microbiologists investigate the role of microorganisms in human and animal diseases and search for ways to prevent and cure these diseases. Dental microbiologists are concerned with the microorganisms found in the mouth, especially their role in tooth decay. Agricultural microbiologists study plant diseases, the role of microorganisms in soil fertility, and spoilage of agricultural products by microorganisms. Industrial microbiologists use microorganisms to produce such products as alcoholic beverages, amino acids, antibiotics, citric acid, and vitamin C. General microbiologists study the basic features of microorganisms, including ecology, genetics, metabolism, physiology, and structure.

Microorganisms also play an important part in sewage treatment and pollution control. Some microorganisms, such as algae and bacteria, are being grown experimentally for use as food. Yeast is used as an ingredient in a variety of foods. It adds flavor and increases the nutritional value of certain foods, such as potato chips. Advances in genetic engineering also have made microbes more useful to people. Scientists can develop new microbes by transferring genes from one organism to another or by making desirable changes in specific genes. Robert E. Marquis

Microcomputer. See **Computer** (Kinds of computers).

Microcrystalline wax is widely used in making special types of paper for packaging. Paper treated with microcrystalline waxes is strong enough to replace tin and steel in many types of containers. These waxes are extracted from the residual oils driven off during the process of refining petroleum (see **Petroleum** [Refining petroleum]). Microcrystalline waxes were first used during the 1920's. William B. Harper

Microelectronics. See **Electronics.**

Microencapsulation is the process of enclosing a substance in a capsule so that the substance can be easily released. Such capsules are made of gelatin, plastic, starch, or other materials. Solids, liquids, and gases can be encapsulated.

Microencapsulation is used in making carbonless copy paper. This paper has a top sheet—coated on the underside with millions of capsules—and a bottom sheet. The capsules release a colorless dye when broken by the pressure of writing or typing. The dye reacts with a thin layer of white clay on the surface of the lower sheet, forming ink. Microencapsulation is also used in making *timed-release* medicines. Such medicines are slowly released in the body so that their effect is extended for as long as 12 hours. Barry Zimmerman

Microfiche. See **Microfilm.**

Microfilm is a kind of photographic film on which reduced images of printed and other materials are recorded. Because these images are reduced in size, microfilm can store large amounts of information in a small space. The process of making microfilm copies is called *microphotography.*

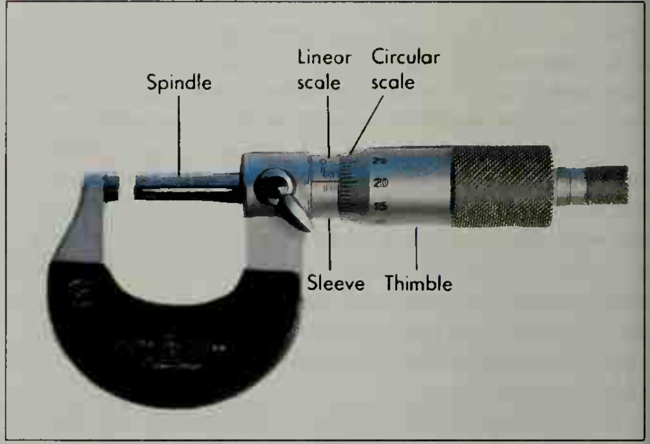
People read the material recorded on microfilm by using a *microfilm reader.* This machine enlarges the images on the film and projects them onto a built-in screen. Some microfilm readers, called *reader-printers,* can also produce a paper copy of the enlarged image.

Uses. Microfilm is widely used by libraries, government offices, and banks and other businesses. Libraries save space by storing old newspapers and magazines on microfilm. Inexpensive microfilm copies of rare and fragile books and manuscripts enable many people to read these materials. Some specialized writings have such a small audience it is not practical to publish them in book form. Instead, they are stored on microfilm.

Government offices preserve such documents as certificates of birth, marriage, and death on microfilm. This practice saves storage space and allows people to use the records without damaging the paper originals. Microfilm can also be used more quickly than paper files.

Banks keep a record of all checks they handle by storing an image of each check on microfilm. Some businesses use microfilm for recording information directly from computers, thereby eliminating the need for bulky paper computer printouts. On the other hand, computers can be used with microfilm filing systems to locate information and project it onto the reading screen.

Types. Microfilm comes in rolls and rectangular sheets. The term *microform* is sometimes used to refer to both the rolls and the sheets. Banks use rolls 16 millimeters ($\frac{5}{8}$ inch) wide and 100 or 200 feet (30 or 60 meters) long. A 200-foot roll holds copies of as many as 44,000 checks reduced 20 to 50 times in size. Rolls of microfilm 35 millimeters ($1\frac{3}{8}$ inches) wide are used mainly for engineering drawings and other large documents.



Sheets of microfilm are called *microfiche.* Microfiche measures 105 by 148 millimeters ($4\frac{1}{8}$ by $5\frac{13}{16}$ inches). The images on a microfiche are arranged in a grid pattern. A single microfiche may contain images of up to 400 pages reduced 18 to 72 times.

An *ultrafiche* has the same overall dimensions as a standard microfiche, but holds many more images. The images on an ultrafiche are reduced 90 times or more. Businesses use ultrafiche to store such material as parts catalogs and price lists.

Most microfilm is designed so that the images are permanent. Some microfilm is made so that images can be replaced with new material. John S. O'Callaghan

Micrometer, *my KRAHM uh tuhr,* is a mechanical device that measures small distances or angles. The term *micrometer* comes from Greek words meaning *small measure,* and micrometers are used for precision measurement. A wide variety of scientific and engineering instruments are equipped with micrometers, including telescopes, microscopes, and surveying tools.

A commonly used micrometer called a *micrometer caliper* measures the thickness of objects. It consists of a micrometer *spindle* or screw that turns inside a fixed nut. The nut is covered by a *sleeve.* The spindle can be closed on the object to be measured by rotating a part

© David R. Frazier Photolibrary

A micrometer caliper measures an object's thickness. This one shows a measurement of just over 3.20 millimeters.

called the *thimble.* The number of turns made by the thimble is measured by two scales, one on the sleeve and the other on the thimble. In many metric micrometers, each rotation of the thimble advances the spindle 0.5 millimeter on the linear scale. The circular scale on the thimble can measure to $\frac{1}{50}$ of 0.5 millimeter, or 0.01 millimeter. Joseph J. Snoble

See also **Caliper.**

Micrometer, *MY kroh MEE tuhr,* also called *micron,* is a metric unit of length. The symbol for the micrometer is μm. One micrometer is equal to 0.000001 meter, or $\frac{1}{25,400}$ inch. The micrometer is used to express extremely short distances and the thickness of very thin objects. Scientists express the size of asbestos fibers, colloidal particles, and various other tiny objects viewed under a microscope in micrometers. Thomas T. Liao

Micronesia, Federated States of, is a country in the North Pacific Ocean. The Federated States of Micronesia (FSM) consists of 607 islands just north of the

The Federated States of Micronesia is a country in the North Pacific Ocean. The island pictured here is one of more than 600 islands that make up the country.

Simon Nathan, The Stock Market

equator in the Caroline Island group. The total land area is only 271 square miles (702 square kilometers). But the islands are scattered across about 1 million square miles (2.5 million square kilometers) of ocean. The United States gained control of the islands in 1945. Although the FSM is now an independent country, the United States is responsible for its defense.

Palikir, on the island of Pohnpei, is the nation's capital. The largest city is Weno in the state of Chuuk (formerly called the Truk Islands). The U.S. dollar serves as the basic unit of currency. The national anthem is "Patriots of Micronesia." For a picture of the flag, see **Flag** (Flags of Asia and the Pacific).

Government of the FSM is headed by a president. A 14-member Congress makes the laws. The people elect the Congress members, and the Congress selects the president. The FSM has four states. The states, named for the chief islands, are Chuuk, Kosrae, Pohnpei, and Yap. Each state elects its own governor and state congress. Village chiefs and traditional leaders play important roles in state governments.

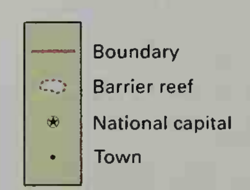
People. About 124,000 people live in the FSM. About 100 of the 607 islands are inhabited. Most of the people are *Carolinians,* also known as Micronesians, but some have Polynesian ancestry (see **Pacific Islands** [People]). The official language is English, but local languages are commonly used. Almost all the people are Christians, but local religious beliefs are strong in some areas.

About three-fourths of the people live in rural areas, and about a fourth in urban areas. Traditional ways of life are changing rapidly as many Carolinians adopt U.S. customs. Many people, especially those in urban areas, depend on food, clothes, and other goods imported from the United States and other countries. Many houses in these areas are made of imported lumber, plywood, or concrete with metal roofing. A more traditional way of life continues in some areas. In these places, relatives live in large family groups and work together to supply food, shelter, and other necessities. They depend largely on fish and on native plants—such as coconuts, breadfruit, and yams—for food. Families build houses with thatched roofs and walls made from palm branches and local wood.

Land and climate. The FSM has two types of islands: (1) mountainous, volcanic islands and (2) ring-shaped coral islands or groups of islands called *atolls.* The soil on the volcanic islands is fertile. Mangrove swamps line the shores, and dense rain forests cover the valleys. The soil supports many crops. In contrast, the atolls generally have infertile soil and relatively little vegetation.

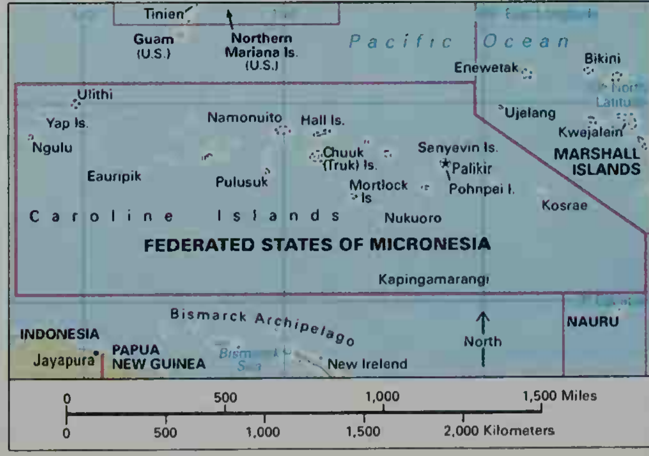
The climate is tropical with an average temperature of about 80 °F (27 °C). Average annual rainfall ranges from about 120 inches (302 centimeters) on Yap to over 300 inches (760 centimeters) on the mountains of Pohnpei. Typhoons are common, especially on the western islands.

Economy. Most people in the FSM make a living by fishing and farming. Yams, coconuts, and breadfruit are the chief crops. Except for the production of *copra* (dried coconut meat), the FSM has little manufacturing.



History. The first people to settle in present-day FSM probably came from Southeast Asia over 3,000 years ago. Spanish explorers of the 1500's became the first Europeans to arrive. Spain formally claimed the Caroline Islands in 1885 and sold them to Germany in 1899.

Japan gained control of the islands in World War I (1914-1918). The United States took them in 1945, at the end of World War II. In 1947, the United States began administering the islands as part of the United Nations Trust Territory of the Pacific Islands. In 1986, the United States granted independence to the FSM. Under a Compact of Free Association, the United States must provide the FSM with defense and economic assistance.



Michael R. Ogden

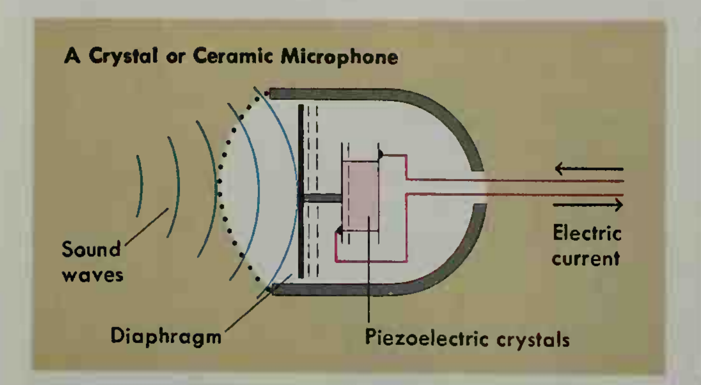
A boom microphone picks up sound on a movie or television set. The boom is an arm that holds the microphone above a performer.

Microphone is a device that changes sound into electric energy. This energy instantly travels over wires or through the air to a loudspeaker or some other instrument that changes it back into sound. Microphones, often called "mikes," are also used in recording sound.

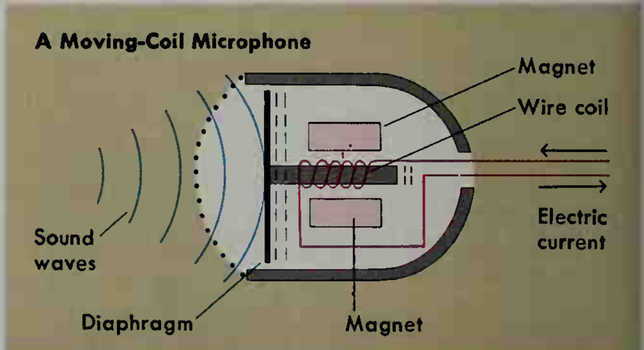
The first microphone was the telephone transmitter, which the American inventor Alexander Graham Bell developed in 1876. Today, microphones are used in announcing over public-address systems and in broadcasting radio and television shows. They are also used in recording the sound for motion pictures and in making compact discs and tape recordings. Citizens band (CB) radios and *ham* (amateur) radios also have mikes.

Microphones of various designs are used for different purposes. CB operators and some entertainers use mikes held in the hand. Other mikes are attached to stands. Still others have an arm, or *boom,* which holds the microphone above a TV or movie performer. The boom and microphone can follow the performer in any direction, but they stay out of view of the camera. *Lavalier microphones,* also called *lapel microphones* and *tie-tack microphones,* are fastened to clothing.

Some microphones pick up sound from all directions, but others are sensitive to sound from only certain directions. An *omnidirectional microphone* picks up sound from all around. A *bidirectional microphone* is used for sound coming from the front or from behind, but not from the sides. A *unidirectional microphone* picks up sound from only one direction.



In some microphones, sound produces variations in an electric current. In others, sound generates a current. In all microphones, the current corresponds to the pattern of the sound waves.



Microphones may be classified according to how they change sound into electric energy. The five main types, in order of increasing complexity, are (1) carbon, (2) crystal and ceramic, (3) moving-coil, (4) ribbon, and (5) capacitor. Moving-coil, ribbon, and capacitor mikes can reproduce sound much more accurately than the other types and are used by the movie, radio, recording, and television industries.

Carbon microphones have a small container called a *button,* which is filled with particles of carbon. An electric current from a generator or battery flows through the carbon. A metal disk called a *diaphragm* presses against the button and vibrates when struck by sound waves. The vibrations cause variations in the current running through the carbon. Carbon microphones are used chiefly in telephones.

Crystal and ceramic microphones contain substances called *piezoelectric crystals.* Pressure on these crystals makes them generate an electric current (see **Piezoelectricity**). Crystal and ceramic microphones may or may not have a diaphragm touching the crystals. An electric current is produced by pressure from sound waves that hit the diaphragm or strike the crystals directly. These microphones are used in ham radios, home tape recorders, and public-address systems.

Moving-coil microphones have a wire coil attached to a diaphragm. The coil and diaphragm are suspended

WORLD BOOK diagrams by Arthur Grebetz

Microphones change sound into electric energy. Many microphones have a metal disk called a *diaphragm,* which vibrates when struck by sound waves. In a crystal or ceramic microphone, *left,* the diaphragm vibrates against substances called *piezoelectric crystals,* creating an electric current. In a moving-coil microphone, *right,* the vibrating diaphragm causes a wire coil to move across a magnetic field. This movement produces an electric current in the coil.

in a magnetic field. When sound waves hit the diaphragm, the coil moves across the field. This movement produces an electric current in the coil. Many CB radios have moving-coil microphones.

Ribbon microphones have a metal ribbon suspended in a magnetic field. An electric current is generated when sound waves hit the ribbon and move it across the field. Both ribbon and moving-coil microphones are called *dynamic microphones.* These mikes are classified as *electromagnetic* because they use a magnetic field to change sound into electric energy.

Capacitor microphones, often called *condenser microphones,* have two metal plates set slightly apart. The plates are electrically charged and serve as a *capacitor,* a device that stores a charge. The front plate is flexible and acts as a diaphragm. The back plate cannot move. Sound waves make the front plate vibrate, which causes variations in the electric current from the capacitor. Capacitor microphones are classified as *electrostatic* because they require an electric charge to change sound into electric energy.

A capacitor microphone produces only a low amount of electrical energy. Therefore, it must have a device called a *preamplifier,* which boosts the mike's signal to a usable level. In most capacitor microphones, called *electrets,* the capacitor is permanently charged and a small battery powers the preamplifier. Electret capacitors are used in hearing aids. Stanley R. Alten

Microprocessor. See Computer chip.

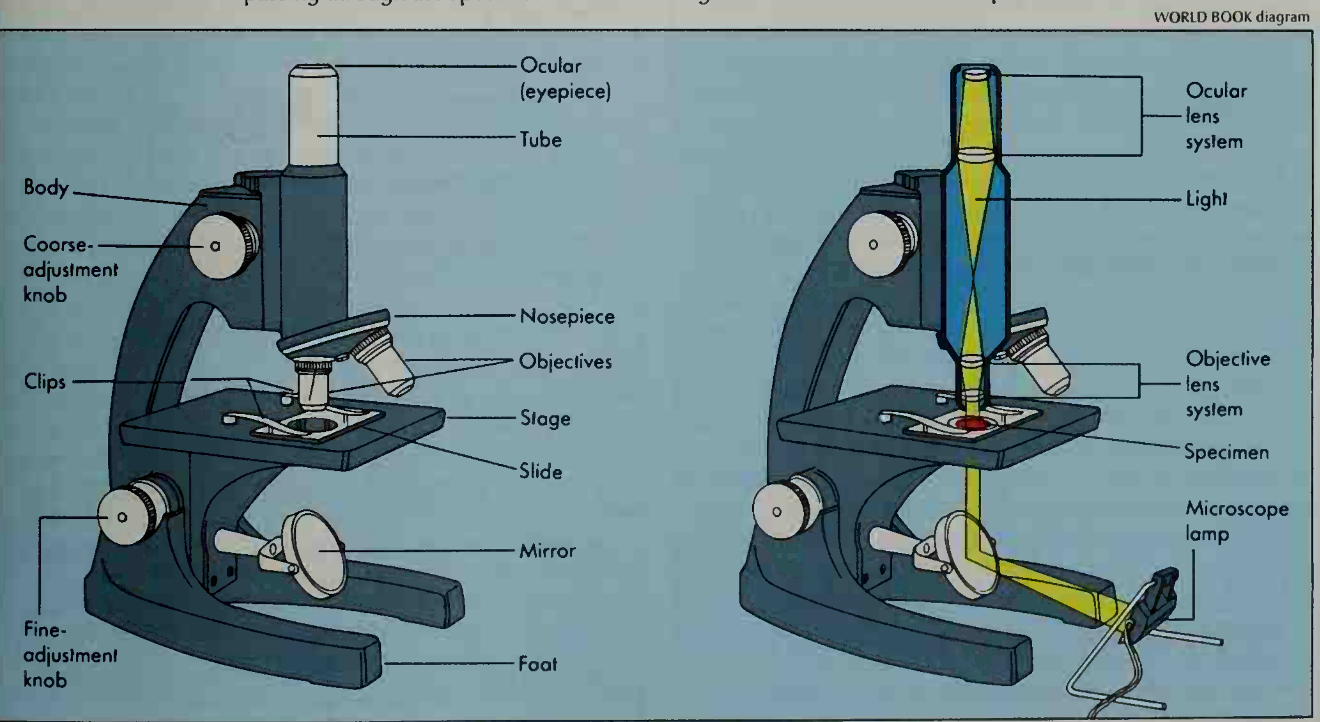
Microscope is an instrument that magnifies extremely small objects so they can be seen easily. It ranks as one of the most important tools of science. Physicians and biologists, for example, use microscopes to examine bacteria and blood cells. Materials scientists and engineers use microscopes to study the crystal structures within metals and alloys (metal mixtures), and to examine computer chips and other tiny electronic devices. Biology students observe algae, protozoa, and other single-cell organisms under a microscope.

There are four basic kinds of microscopes: (1) *optical,* or *light;* (2) *electron;* (3) *scanning probe;* and (4) *ion.* This article discusses mainly optical microscopes.

How an optical microscope works. An optical microscope has one or more lenses that *refract* (bend) the light rays that shine through, or are reflected by, the specimen being observed (see Lens). The refracted light rays make the specimen appear much larger than it is.

The simplest optical microscope is a magnifying glass, which has only one lens (see Magnifying glass). The best magnifying glasses can magnify an object by 10 to 20 times.

Magnification power is symbolized by a number and the abbreviation X. For example, a 10X magnifying glass magnifies a specimen by 10 times.



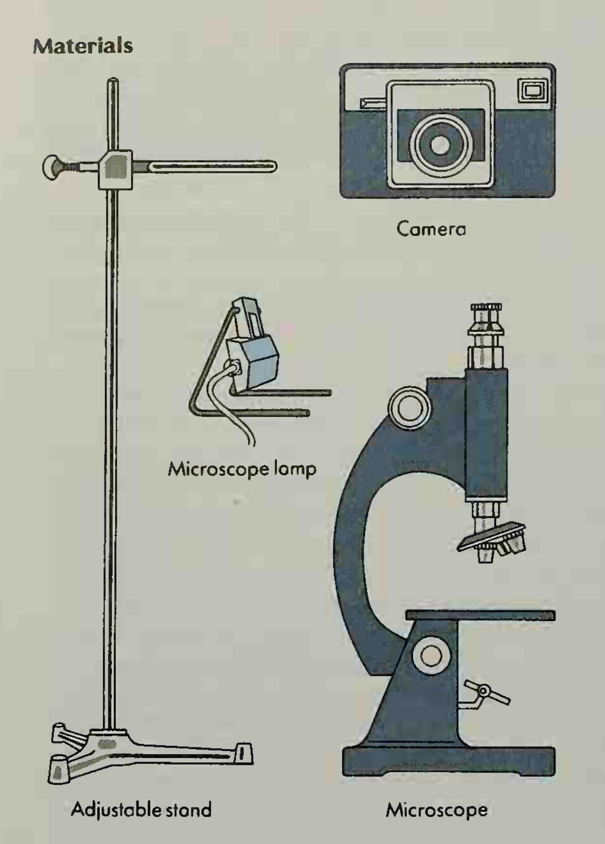
A *compound microscope* uses two or more sets of lenses to provide higher magnifications. Each set of lenses functions as a unit and is referred to as a *lens system.* A compound microscope has an *eyepiece,* or *ocular, lens system,* often called simply the *ocular;* and one or more *objective lens systems,* often called *objectives.*

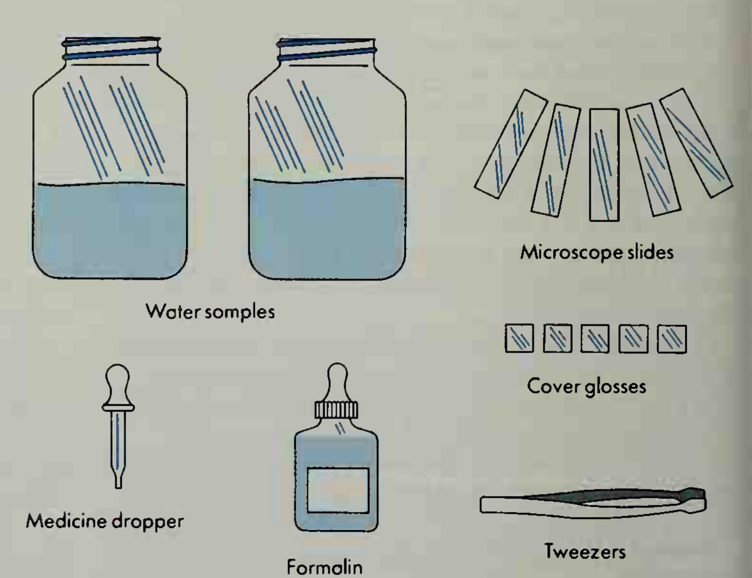
In microscopes with only one objective, that lens system and the ocular are mounted at opposite ends of a tube. The objective produces a magnified image of the specimen. The ocular then magnifies this image.

In microscopes with two or more objectives, the objectives are mounted in a rotating *nosepiece* connected to the end of the tube opposite the ocular. The person operating the microscope rotates the nosepiece to align one of the objectives with the opening in the end of the

Parts of an optical microscope The diagram at the left shows the external parts of an optical microscope. A person adjusts these parts to view a specimen. The cutaway diagram at the right shows the path that light follows when passing through the specimen and then through the lenses of the microscope.

WORLD BOOK diagram



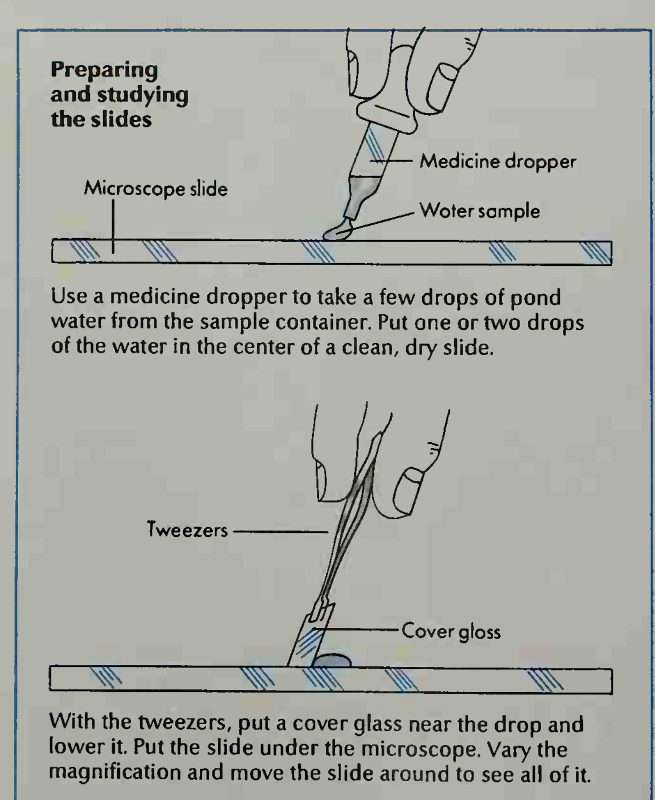


A *World Book* science project

The microscopic world

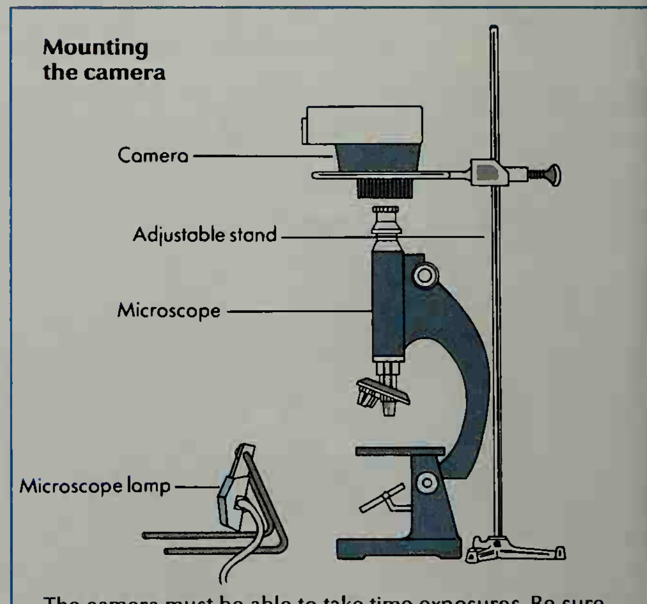
The purpose of this project is to use a microscope to study the tiny organisms that live in water. The photographs with this project will help you identify the organisms you see. By using a camera that takes time exposures, you can take your own pictures through the microscope.

Materials



Materials for this project are shown above. The microscope should be able to magnify by at least 400X. With it, you will need microscope slides, cover glasses, and a microscope lamp. Water samples should come from a pond or slow-moving stream. To take pictures, you will need a camera and stand, and formalin to kill the organisms. CAUTION: Formalin is extremely irritating to the eyes and nose. Handle it with care and wash your hands after using it.

WORLD BOOK illustrations by Arthur Grebetz



Preparing and studying the slides

Use a medicine dropper to take a few drops of pond water from the sample container. Put one or two drops of the water in the center of a clean, dry slide.

With the tweezers, put a cover glass near the drop and lower it. Put the slide under the microscope. Vary the magnification and move the slide around to see all of it.

Mounting the camera

The camera must be able to take time exposures. Be sure it contains no film and then remove its back before mounting. After focusing the microscope, place the camera on an adjustable stand over it. Put a piece of waxed paper over the camera's back in place of the film. Then open the shutter and move the camera up or down until you get a sharp picture on the waxed paper.

tube. This objective works with the ocular to provide the desired magnification. Many compound microscopes have three objectives that magnify by 4X, 10X, and 40X. When used with a 10X ocular, these microscopes provide magnifications of 40X, 100X, and 400X.

In addition to magnifying a specimen, a microscope must produce a clear image. This capability is called the *resolving power,* or *resolution,* of the microscope. In an optical microscope, the *wavelength* (distance between wave crests) of the light waves that illuminate the specimen limits the resolving power. The wavelength of visible light ranges from about 4,000 to 7,000 *angstroms.* (One angstrom equals 1/10,000,000 millimeter [about 1/250,000,000 inch]). The best optical microscopes cannot resolve parts of a specimen that are closer together than about 2,000 angstroms. To obtain higher resolutions, scientists use other types of microscopes.

Parts of an optical microscope. Most optical microscopes used for teaching have three main parts: (1) the tube, which has already been described; (2) the *foot;* and (3) the *body.* The foot is the base of the instrument. The body is an upright support that holds the tube. At the lower end of the body is a mirror. The specimen lies on the *stage,* a platform above the mirror. The mirror reflects light up through an opening in the stage to illuminate the specimen. The operator can move the tube within the body by turning a *coarse-adjustment knob.* This focuses the microscope. A *fine-adjustment knob* moves the tube a small distance for final focusing of a high-power objective.

Using an optical microscope. To prepare a microscope for use, turn the nosepiece to bring the objective with the lowest power into viewing position. Next, turn the coarse-adjustment knob to lower the tube until the objective is just above the opening in the stage. Finally, look through the ocular and adjust the mirror so a bright circle of light appears.

Many specimens viewed through a microscope are transparent or have been made transparent. The technique of preparing specimens is called *microtomy* (see **Microtomy**). Specimens are mounted on glass slides that measure 3 inches long and 1 inch wide (76 by 25 millimeters).

To view a slide, place it on the stage with the specimen directly over the opening. Hold the slide in place with clips that are attached to the stage. Look through the ocular and turn the coarse-adjustment knob to raise the objective until the specimen comes into focus. To avoid breaking the slide or the objective, never lower the lens when a slide is on the stage.

Advanced optical microscopes are used in research and have extra-powerful lens systems. Many such microscopes have a 100X objective and a 20X ocular, which together provide a magnification of 2,000X. Some high-powered microscopes have *oil immersion* objectives. The bottom lens of the objective touches a drop of special oil placed on the slide. The oil refracts light in a way that provides a better image at high magnification.

Other microscopes used for research have additional features. For example, a microscope with a *binocular tube* splits the light from the objective into two beams. An ocular for each beam enables the operator to view the specimen with both eyes. *Trinocular tubes* split the light into three beams—one for each eye and one for a built-in camera. A *stereoscope* microscope provides a three-dimensional view of the specimen. Such a microscope has an objective and an ocular for each eye.

Scientists use special optical microscopes to study details that are not normally visible. For example, a *phase contrast microscope* changes the phase relationship between the light waves passing through the specimen and those not passing through it. This action makes some parts of the specimen appear brighter and other parts darker than normal. Parts of a transparent object that vary in thickness or have certain other optical properties can be made visible in this way.

A *dark-field microscope* prevents light from the lamp from shining directly up the tube. Instead, the microscope uses only light scattered by the specimen. The specimen appears bright against a black background.

A *scanning optical microscope* does not illuminate the entire specimen at once. Instead, the microscope directs a laser beam at a small spot on the specimen. An electronic device called a *photodetector* measures the amount of light reflected from, or shining through, the specimen. The beam then scans the specimen as the photodetector takes measurements at a large number of spots. A computer combines the measurements to produce an image on a TV-like monitor screen.

In a *confocal scanning optical microscope,* a photodetector measures light readings from various depths in the specimen. A computer uses the measurements to create a three-dimensional image. The operator can rotate the image to examine it from any angle.

Other kinds of microscopes. *Electron microscopes* use a beam of electrons rather than a beam of light to produce magnified images. Electron wavelengths are much shorter than those of visible light. As a result, electron microscopes can resolve much finer detail than optical microscopes can. Some electron microscopes can resolve objects that are less than 2 angstroms apart, which is sufficient to reveal the fundamental atomic structure of the specimen.

There are two basic types of electron microscopes. A *transmission electron microscope* passes a broad beam of electrons through a specimen slice a few hundred angstroms thick. A *scanning electron microscope* scans a focused beam across the surface of the specimen. See **Electron microscope.**

Scanning probe microscopes scan a specimen with a sharp point called a *probe.* There are two main types of scanning probe microscopes: (1) the *scanning tunneling microscope* (STM) and (2) the *atomic force microscope* (AFM). In the STM, the probe does not quite touch the specimen. An electric current flows between the probe and the specimen. A computer uses measurements of this current to create an image. An STM can resolve surface atoms that are less than 2 angstroms apart.

In the AFM, the probe usually gently touches the specimen's surface. As the probe scans the specimen, it reacts to the roughness of the surface by moving up and down. Electronic devices measure this movement and send their results to a computer, which creates an image. The AFM can produce images of specimens, such as animal tissue, through which electric current does not flow readily. See **Scanning probe microscope.**

An *ion microscope,* also known as a *field-ion microscope,* is used to examine metals. It creates an image

of the crystal structure of the tip of an extremely sharp metal needle. An electric field applied to the tip repels charged helium, neon, or argon atoms, which spread out and strike a special screen. The screen glows where the atoms strike it, forming an image of the arrangement of atoms in the metal. See **Ion microscope.**

History of the microscope. Engravers probably used water-filled glass globes as magnifying glasses at least 2,000 years ago. The Romans may have made magnifying glasses from rock crystal. Glass lenses of the type now used were introduced in the late 1200's.

Historians generally credit a Dutch spectacle-maker, Zacharias Janssen, with discovering the principle of the compound microscope about 1590. In the 1670's, Anton van Leeuwenhoek, a Dutch amateur scientist, made single-lens microscopes that could magnify up to 270X. Leeuwenhoek was the first person to observe microscopic life and record his observations.

Few improvements occurred until the early 1800's, when better glass-making methods produced lenses that provided undistorted images. German scientists demonstrated the first electron microscope in 1931. The ion microscope was invented in 1951. In 1981, Swiss and West German scientists demonstrated the first scanning tunneling microscope. Stephen J. Pennycook

Microtome, *MY kruh tohm,* is a device used to cut materials very thin so that they can be seen in cross section under a microscope. It has a holder in which the specimen is clamped, a razor-sharp knife, a guide for the knife, and a turnscrew which regulates the thickness of the slice. See also **Microscope; Microtomy.**

WORLD BOOK photo by Steinkamp/Ballogg

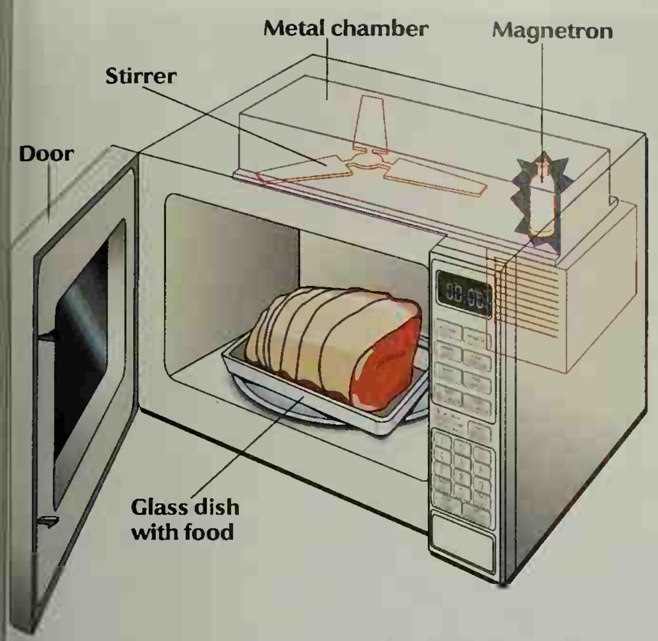
A microtome cuts thin slices of human tissue for examination under a microscope. Wax holds the tissue together so the microtome can slice it thin enough for light to pass through.

Microtomy, *my KRAHT uh mee,* originally meant *microscopic cutting.* But it now means the art of preparing objects for examination with a microscope. Without preparation, few objects can be properly examined with a microscope (see **Microscope**). A piece of metal, for example, must be highly polished and etched before its structure can be seen with a microscope.

Scientists prepare biological materials either as smears, squashes, wholemounts, or sections. *Smears* are made by applying a thin layer of blood or other organic fluid to a microscopic slide. Technicians dry and stain the layer so the cells can be seen. Geneticists make *squashes* by crushing cells in order to see the number and shape of the chromosomes (see **Chromosome**). *Wholemounts* are prepared from whole microscopic organisms that are killed in a *fixative* to keep their shape. They are then stained. Alcohol removes the water, and clove or cedar oil makes the objects transparent. Technicians next mount the objects in a drop of resin on a glass slide, which they cover with a glass *coverslip* about $\frac{1}{5,000}$ inch (.005 millimeter) thick.

Scientists study plant and animal tissues in *sections* about $\frac{1}{2,500}$ inch (.01 millimeter) thick. The tissues are hardened and dried out, then soaked in wax and shaped into blocks. The wax supports the tissues so they can be sliced into sections on a *microtome* (see **Microtome**). The sections are cemented to slides with egg white and the wax is dissolved. They are then stained and preserved under a coverslip. An *ultramicrotome* is used to prepare specimens for the electron microscope. It cuts sections about $\frac{1}{1,300,000}$ inch (.02 micrometer) thick. The specimens are so thin that the electron beam of the microscope can penetrate them. Stephen J. Pennycook

Microwave is a short radio wave. It varies from 1 to 300 millimeters (about $\frac{1}{25}$ to 12 inches) in length. Like light waves, microwaves may be reflected and concentrated. But they pass easily through rain, smoke, and fog, which block light waves. They can also pass through the *ionosphere,* which surrounds the earth and blocks or reflects longer radio waves. Thus, microwaves are well suited for long-distance, satellite, and space communications and for control of navigation.



Microwaves first came to public notice through the use of radar in World War II (1939-1945). Today, many satellite communications systems use them. In TV, microwave transmission sends programs from pickup cameras in the field to the TV transmitter. These programs can then be sent via satellites to locations around the world. Microwaves can also cook food in microwave ovens. Vijai K. Tripathi

See also **Communications satellite; Microwave oven; Radar; Radio; Television.**

Microwave oven is an appliance that heats food by penetrating it with short radio waves. The waves cause molecules in food to vibrate rapidly. Friction among the moving molecules creates heat, which cooks the food.

Microwave cooking generally takes much less time than cooking with electric or gas ovens. This is because microwave ovens produce heat directly inside the food, but regular ovens cook food gradually, from the outside in. When properly prepared, meats and vegetables cooked in a microwave oven tend to retain more of their natural juices than when cooked by other methods.

Microwaves are produced in a microwave oven by an electronic vacuum tube called a *magnetron.* In most such ovens, these waves travel through a metal chamber

WORLD BOOK diagram by Bensen Studios

A microwave oven has an electronic vacuum tube called a *magnetron* that produces microwaves. The waves travel through a metal chamber to the *stirrer,* which scatters them into the oven. There, the microwaves penetrate food and cook it quickly.

to the *stirrer,* a device similar to an electric fan. The stirrer scatters the waves around the oven's metal interior. The waves bounce from wall to wall until they enter the food in the oven.

Microwaves penetrate food to various depths, depending on the food's molecular makeup and thickness. For example, microwaves can travel about $1\frac{1}{2}$ inches (3.8 centimeters) into most meats. If the meat is thicker, the waves do not penetrate it completely. Instead, the meat's inner layers are cooked by heat from the outer layers.

Microwaves pass through glass, paper, and most kinds of china and plastics. Therefore, most containers made of these materials may be used to hold food in microwave ovens. Metal cookware should be avoided because it reflects microwaves, preventing them from entering the food. In addition, metal containers may reflect enough energy back to the magnetron to damage it.

Microwaves that leak from an oven may pose a hazard to people nearby. In addition, such leaks reduce the oven's efficiency. Secure door seals and proper door closure help prevent microwave leakage. Microwave ovens that do not close securely should never be used.

Manufacturers introduced microwave ovens for home use in the 1950's. Sales of these appliances have grown rapidly since the mid-1970's. Evan Powell

Midas, *MY duhs,* was a character in Greek mythology. He was king of Phrygia, an ancient country in central Asia Minor. The god Dionysus gave Midas the power to turn everything he touched into gold, because he had helped Dionysus's teacher Silenus (see Dionysus).

At first, Midas's miraculous power pleased him. But soon it became a curse, because even his food turned to gold the moment he touched it. He prayed to Dionysus to help him, and the god told him to bathe in the river Pactolus. Midas washed himself, and the magic touch left him. But the sands of the river turned to gold.

Midas acted as judge at a musical contest between Apollo and Pan (see Apollo; Pan). He awarded the prize to Pan, and Apollo angrily turned Midas's ears into those of an ass. Midas was ashamed and kept his ears covered. But he could not hide them from the slave who was his barber. The slave did not dare tell anyone about the king's ears because he feared punishment. He dug a hole and whispered the truth into it. Reeds grew out of the soil and whispered the secret when the wind blew.

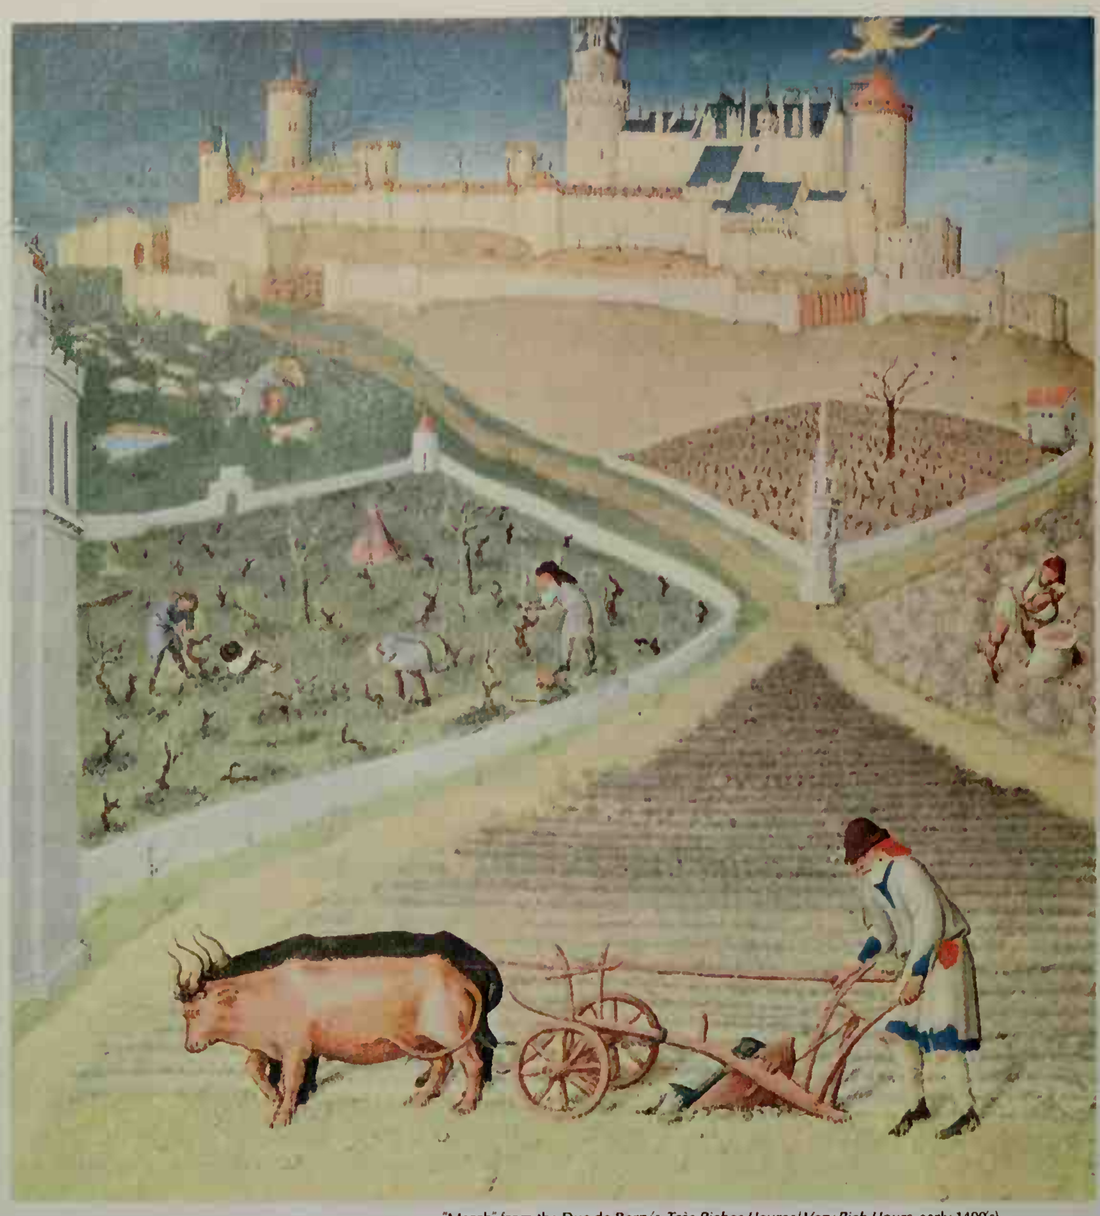
The expression *to have the Midas touch* is used to describe a person who makes money in everything he or she does. A *Midas* is a wealthy person. Jon D. Mikalson

Middle age refers to an arbitrary period in a person's life between early adulthood and old age. In industrial societies, such as the United States and Canada, this period now usually extends from about the age of 40 to 65. However, there is no noticeable change in physical or behavioral functioning at either of these ages. The range of middle age may vary in different societies. For example, in nonindustrialized countries, people may be considered old by the age of 40.

In Western industrial societies, middle age is often characterized by an inclination to "settle down." Middle-aged people accept obligations and responsibilities, and work harder to develop a consistent pattern of relationships. They tend to place increasing value on their family life and friendships, even if they have successful careers. Many people may feel closer to their own elderly parents, having achieved a deeper understanding of what the older generation went through. Parents often become more open and respectful with their children.

Researchers believe that some middle-aged people may not enjoy this part of life because they fear old age and value youth too much. However, studies of people moving from youth through middle age have found many sources of satisfaction. Some middle-aged people feel that they still have the physical vigor to carry out their plans and responsibilities. Often life satisfaction is enhanced by the skills and experiences acquired over the years. As a result, problems in middle age can often be handled before they become crises.

Each new group of people that enters middle age comes along at a particular point in social history with unique values, pressures, and opportunities. For example, characteristics of middle-aged people today include a greater number of women in the labor force than ever before, a greater emphasis on physical fitness, and a higher divorce rate.



Middle-aged people today also face new challenges. These challenges include (1) major changes in the workplace due to the increasing use of computers and (2) increasingly permissive standards of sexual expression. Thus, middle age is far from a quiet, uneventful period of life. But many middle-aged people benefit from their broad life experience and well-developed skills. Many are also enrolling in college and finding other opportunities to make the most of their potential as vital, creative people. Robert J. Kastenbaum

Middle Ages

Middle Ages is a term that describes the period in European history from about the 400's through the 1400's. The Middle Ages are also called the *medieval period,* from the Latin words *medium* (middle) and *aevum* (age).

In the late 1300's and the 1400's, Renaissance writers introduced the idea of a "middle age" between ancient and modern times. They believed that after the Roman Empire collapsed in western Europe in the 400's, culture and society declined until the revival of Greek and Roman ideas in their own time. As a result of this belief, the Middle Ages are sometimes incorrectly called the Dark Ages. But the Middle Ages were a dynamic time in human history. During this period, many Europeans converted to Christianity, and Islam became a dominant religion in the southern Mediterranean. In addition, the political, ethnic, and linguistic borders of modern Europe came into being during the Middle Ages.

This article discusses what happened in western Europe from the 400's through the 1400's. To learn how other peoples influenced medieval civilization, see the *World Book* articles on **Byzantine Empire; Muslims;** and **Rome, Ancient.** See also **World, History of the.**

Deborah Mauskopf Deliyannis, the contributor of this article, is a Lecturer of History and Art History at Indiana University.

The fall of Rome

The Late Roman Empire. At its height, the Roman Empire included much of Europe, North Africa, and the Middle East. It was so big, and its government was so complex, that it had difficulty defending its borders from attacks. To help resolve this dilemma, the empire was split into two administrative units starting in the late 200's. The empire became permanently divided in the late 300's. The West Roman Empire consisted of western

Illustration from an illuminated manuscript (1448); National Library of Austria, Vienna

Life in the Middle Ages centered around control of the land. Land was ruled by a powerful lord, defended by his knights, and farmed by his peasants. The lord's home, *left,* was a mighty stone castle built for defense. The Christian church was an important institution in the Middle Ages. When a town wanted to build a new cathedral, the townspeople sometimes helped construct it. These community building projects were called *fatigues.*

Europe and the western half of North Africa. The East Roman Empire was made up mainly of the Balkans and present-day Turkey, Lebanon, Syria, Israel, and Egypt.

The Germanic invasions. Germanic peoples came from northern Europe and Scandinavia. They began to move into central Europe around 1000 B.C. By the A.D. 200's, they occupied regions in the Rhine and Danube river basins along the northern and northeastern boundaries of the Roman Empire. Some Germans adopted the civilization of their Roman neighbors. They traded with Roman merchants and enlisted in Roman armies.

The Romans called the Germans *barbarians* (uncivilized people). The Germans lived in tribes, each governed by a chief. People knew them as fierce warriors.

In the late 300's, Germans began moving into the Roman Empire to escape the Huns, a central Asian people who were invading the region north of the Black Sea. The Huns later pushed into central Europe, and Germanic tribes began invading the West Roman Empire, which had lost much of its power to defend itself. Between 400 and 500, the Visigoths established themselves in Spain; the Vandals moved into North Africa; and the Angles, Saxons, and Jutes settled in Great Britain. The Franks established a kingdom in Gaul (now mainly France), and the Ostrogoths claimed Italy. See **Angles; Franks; Goths; Jutes; Saxons; Vandals.**

A German commander of the Roman army deposed the last ruler of the West Roman Empire in 476. However, the East Roman Empire survived as the Byzantine Empire until 1453. See **Byzantine Empire.**

The Germanic kingdoms

Barbarian Europe. The Germanic invasions divided the West Roman Empire into many kingdoms. Germans were a tiny minority of the population of their new kingdoms. In most cases, Germans worked with Roman leaders to create governments that reflected both peoples' traditions. Over time, the Roman and Germanic ways of life blended to create medieval culture.

The Roman legal system had been based on written case law. German law was based on oral tradition. In the new kingdoms, the Germanic rulers had their oral traditions written down so they would have the same status as Roman law. One of the Germans' methods of determining guilt was called *trial by ordeal.* The accused person had to undergo a test, such as picking up a red-hot iron bar with a bare hand. If the burns healed within three days, it was declared that God had shown the person was innocent. See also **Trial by combat.**

Government in the Germanic kingdoms was on a much smaller scale than Roman government had been. Taxes were a major source of government income during the Roman Empire, but Germanic kings received money from the profits of their lands or from military conquest. Germanic governments did not have a large income and could not build roads or support schools. Kings ruled with the support of the nobility. Nobles were the king's warriors and the major landowners. In return for their loyalty, nobles expected the king to provide land, goods, or privileges.

The Germanic invasions destroyed most of the European trade that the Romans had established. Few people used the great system of stone roads that had encouraged trade and communication among cities of the Roman Empire. Money went out of use almost completely.

By the 800's, most of western Europe was divided into large estates of land called *manors.* A few wealthy landowners, called *landlords* or *lords,* ruled the manors. Most of the people were peasants who worked the land and often were forbidden from leaving it. Each village on a manor produced nearly everything needed by its people. This system of obtaining a living from the land was called *manorialism.* See **Manorialism.**

Towns lost their importance in manorial society. Some towns were completely abandoned. Most became centers of religious activity only. The middle class, which had engaged in trade and industry, disappeared. Education, cultural activities, and literacy declined. Almost all state and city schools vanished. Ancient Greek and Roman knowledge and culture were preserved on a reduced scale, primarily by the church.

The Christian church had become the official church of the Roman Empire by 400. Almost all Germanic peoples, except the Angles, Saxons, and Jutes, were already Christians or became Christians soon after they entered the empire. Germanic kings supported the church, and the church supported them.

Church leaders took over many functions of government after the Roman Empire collapsed. In many cases, they were major landowners. The church encouraged literacy and administered justice. It also provided hospitals for the sick and rest stops for travelers.

Two church institutions, the *cathedral* and the *monastery*, became centers of learning in the early Middle Ages. Cathedrals were the churches of bishops. Monasteries were communities of men and women who gave up worldly life to serve God through prayer and work. The monks of some monasteries and the clergy of the cathedrals helped continue the reading and writing of Latin and preserved many ancient manuscripts. They also founded most schools in Europe. In about 600, the church began a vigorous, organized effort to send missionaries to non-Christian areas of northern and eastern Europe.

The rise of Islam. In about 610 in Mecca, a city in the Arabian Peninsula, the Prophet Muhammad declared that he had begun to receive revelations from God. Muhammad began to preach the religion of Islam and converted many Arabs. Followers of Islam, called Muslims, began expanding into neighboring areas. Between 630 and the early 700's, Muslim armies easily conquered the Persian Empire and took Syria, Palestine, and North Africa from the Byzantine Empire. They also seized Spain from the Visigoths.

Until the 1100's, the Muslims dominated shipping on the Mediterranean Sea, and contact between western Europe and the Byzantine Empire was difficult. But the Muslims maintained extensive trade and communication networks in their territories. They introduced many new crops and such industries as papermaking and silk-weaving to western Europe. Muslim scholars translated many ancient Greek texts into Arabic.

The Carolingian Empire united much of western Europe under one ruler in the late 700's. The Carolingians were a family of Frankish kings who ruled from the mid-700's to 987. The most important Frankish rulers were Pepin the Short and his son Charlemagne.

Popes began to exercise influence over European politics in the mid-700's. In 751, with the pope's support, Pepin the Short, the Frankish kingdom's chief government official, became king of the Franks. Charlemagne inherited the throne in 768. He conquered much of what is now Germany and most of Italy, uniting more territory in western Europe than any ruler had since the Roman Empire ended. In 800, the pope crowned Charlemagne emperor of the Romans.

In creating and running their empire, the Carolingian rulers depended on loyal noblemen called *vassals*. Vassals pledged their loyalty to the king and promised to serve him. The king then became a *lord* to his vassal. The Carolingian kings rewarded their vassals by granting them estates called *fiefs*. A fief included the use of the manors on the land, the buildings and villages of each manor, and the peasants who farmed the manor. If a vassal was disloyal to his lord, the lord could demand the return of the fief. Most vassals served as knights in the king's army. Many vassals also had their own knights.

The early Middle Ages reached their highest point of achievement during Charlemagne's rule. He worked to protect and reform the church. Although he never learned to write, he supported education and scholarship. He established a school at his palace in Aachen. Teachers from across Europe gathered there. They organized schools and libraries and copied ancient manuscripts. These activities caused a new interest in learning called the *Carolingian Renaissance*. See **Charlemagne**.

Charlemagne's empire did not last long after his death in 814. His three grandsons fought each other for the title of emperor. In 843, the Treaty of Verdun divided the empire into three parts, one for each grandson. But Magyars, Muslims, and Vikings attacked the divided empire soon after the treaty was made. By the late 800's, the Carolingian Empire no longer existed.

Feudal Europe

Feudalism. After the end of Charlemagne's empire, Europe was again divided into kingdoms. Most of the kings had little control over their kingdoms. As a result, hundreds of vassals—with such titles as *prince, baron, duke,* or *count*—became independent rulers of their own fiefs. These noblemen ruled their fiefs through a form of government now called feudalism.

Under feudalism, the noblemen who controlled the land also had political, economic, judicial, and military power. Each nobleman collected taxes and fines, acted as judge in legal disputes, and maintained an army of knights within his own territory. He also supervised the farming of the manors on his fief. The fief-holders were the ruling class in Europe for more than 400 years.

A typical member of the feudal ruling class was a nobleman, a knight, a vassal, and a lord—all at the same time. He was a nobleman because he had been born into the noble class. He became a knight when he decided to spend his life as a professional warrior. He became a vassal when he promised to serve a king or other important person in return for a fief. Finally, he became a lord when he gave part of his own land to persons who promised to serve him.

A lord and a vassal had rights and duties toward each other. A lord promised his vassal protection and justice, and the vassal gave the lord various services, most of which were military. Feudal warfare was common in Europe. If a lord and his vassal performed their duties, there was peace and good government. But if either disregarded his duties, war broke out between them. The lords fought among themselves as well, because they often tried to seize each other's land. The church, which had its own princes and fiefs, was part of the feudal system, so it also suffered in the warfare. See **Feudalism**.

Feudal government. During the 900's and 1000's, much of western Europe was divided into feudal states. A powerful lord ruled each state as if he were king. The kings themselves ruled only their own royal lands.

In France, the king ruled only the area called the Île-de-France, a narrow strip of land centered near Paris. The rest of France was divided into such feudal states as Aquitaine, Anjou, Brittany, Flanders, and Normandy. In some states, no lord was powerful enough to establish a strong government. But in Anjou, Flanders, and Normandy, capable lords provided strong governments.

Under William the Conqueror, England became the strongest feudal state in Europe. William, the duke of Normandy, invaded England in 1066. After defeating the Anglo-Saxon army, he became king of England. He then established the feudal system in England by making all

landholders his vassals. See **Norman Conquest; Normandy; William I, the Conqueror.**

Feudalism did not provide strong government in Germany or Italy. For hundreds of years, powerful dukes fought the kings. Otto I, one of the most powerful German kings, won control over the dukes in the mid-900's. He then tried to create an empire like Charlemagne's. After conquering lands east of Germany, Otto invaded Italy. In 962, the pope crowned Otto emperor of what later became known as the Holy Roman Empire. The empire consisted mainly of Germany and northern Italy. But the German dukes tried repeatedly to regain greater control of their territories. By the early 1200's, the empire was weak and continually divided by warfare.

The power of the church became the single great force that bound Europe together during the feudal period. The church touched almost everyone's life in many important ways. The church baptized a person at birth, performed the ceremony at the person's marriage, and conducted burial services when the person died.

The church also became the largest landholder in western Europe during the Middle Ages. Many feudal lords gave fiefs to the church as donations or in return for services performed by the clergy. At first, feudal lords controlled the church, but the church gradually won a large degree of freedom.

Although church leaders did not take a direct part in feudal warfare, they controlled the lords with their own types of weapons. One great power of the church was its threat of *excommunication.* To excommunicate a person meant to cut the person off completely from the church and take away the person's hope of going to

Europe about 1000

In the 900's and 1000's, much of Europe was divided into feudal states, many of which were called *duchies* or *counties.* Feudal lords, who had such titles as *duke* or *count,* often had more power than the kings. Other parts of Europe were controlled by the Byzantine Empire (divided into *themes*) and by Muslims known as Saracens.

WORLD BOOK map

heaven. If a lord continued to rebel after being excommunicated, the church disciplined him with an *interdict.* This action closed all the churches on the lord's land. No one on the land could be married or buried with the church's blessing, and the church bells never rang. The people usually became so discontented that they rebelled, and the lord finally yielded to the church.

Life of the people. Europe during the 900's was poor, underdeveloped, and thinly populated. At least half the land could not be farmed because of thick forests or swamps. War, disease, famine, and a low birth rate kept the population small. People lived an average of only 30 years. There was little travel or communication, and less than 20 percent of the people went farther than 10 miles (16 kilometers) from their birthplace. The people of western Europe consisted of three groups. The *lords* governed the large fiefs and did all the fighting. The *clergy* served the church. The *peasants* worked on the land to support themselves, the clergy, and the lords.

The lords. A lord's life centered around fighting. He believed that the only honorable way to live was as a professional warrior. The lords and their knights, wearing heavy armor and riding huge war horses, fought with lances or heavy swords.

The behavior of all fighting men gradually came to be governed by a system called *chivalry.* Chivalry required that a man earn knighthood through long and difficult training. A knight was supposed to be courageous in battle, fight according to certain rules, keep his promises, and defend the church. Chivalry also included rules for gentlemanly conduct toward women. In peacetime, a lord and his knights entertained themselves by practicing for war. They took part in *jousts* (combat between two armed knights) and *tournaments* (combat between two groups of knights). See **Knights and knighthood**.

The lord lived in a manor house or a castle. Early castles were simple forts surrounded by fences of tree trunks. Later castles were mighty fortresses of stone. In the great hall of the castle, the lord and his knights ate, drank, played games, and gambled at the firesides.

Women were not allowed to be knights and could not participate directly in feudal government. The lord's wife, called a *lady,* was trained to sew, spin, and weave. When the lord was away, at war or performing his feudal responsibilities, the lady was in charge of managing and defending the estate. She was also in charge of children in the household. But she had few rights. Decisions about whom a woman married, and what happened to her if she was widowed, were mainly in the hands of the men in her family or her feudal overlord.

The clergy. Most bishops and other high-ranking clergymen were noblemen who devoted their lives to the church. They ruled large fiefs and lived much like other noblemen. Some of these clergymen were as wealthy and powerful as the greatest military lords.

Monks who lived in a monastery were required to live according to its rules. They had to spend a certain number of hours each day studying, praying, and taking part in religious services. Some monks who were outstanding scholars left the monastery and became advisers to kings or other rulers.

Many peasants who became clergymen served as priests in the peasant villages. Each village priest lived in a small cottage near his church. He gave advice and help to the peasants, settled disputes, and performed church ceremonies. The priests collected fees for baptisms, marriages, and burials. But most priests were as poor as the peasants they served.

The peasants had few rights and were almost completely at the mercy of their lords. A peasant family worked together to farm both the lord's fields and their own. Peasants also performed whatever other tasks the lord demanded, such as cutting wood, storing grain, or repairing roads and bridges.

Peasants paid many rents and taxes. They had to bring grain to the lord's mill to be ground, bake bread in the lord's oven, and take grapes to the lord's wine press. Each of these services meant another payment to the lord. Money was scarce, so the peasants usually paid in wheat, oats, eggs, or poultry from their own land.

Peasants lived in crude huts and slept on bags filled with straw. They ate black bread, eggs, poultry, and such vegetables as cabbage and turnips. Rarely could they afford meat. They could not hunt or fish because game on the manor belonged to the lord.

The High Middle Ages

Medieval civilization reached its highest point of achievement between the 1000's and the late 1200's. This period is called the *High Middle Ages.*

In the 1000's, many capable lords provided strong governments and periods of peace and security under the feudal system. Also, some evidence indicates that a small variation in the earth's climate produced a *climatic optimum,* which gave western Europe warmer and drier weather conditions that were favorable for farming. This period lasted from about 1000 to about 1300. The population grew, farm yields expanded, and many people became more prosperous. As a result, more people were able to devote themselves to new ideas and activities.

Economic recovery. As government improved, so did economic conditions. Merchants again traveled the old land routes and waterways of Europe. Towns sprang up along the main trade routes. Most early towns developed near a fortified castle, church, or monastery where merchants could stop for protection. The merchants, and the craftworkers who made the goods sold by the merchants, gradually settled in the towns.

Europe's population began to increase during the 1000's, and many people moved to the towns in search of jobs. At the same time, peasants began to leave the manors to seek a new life. Some became merchants and craftworkers. Others farmed the land outside the towns and supplied the townspeople with food. Medieval towns, which arose mainly because of the growth of trade, encouraged trade. The townspeople bought goods and also produced goods for merchants to sell. The peasants learned better ways of farming and produced more and more food for the growing population. Peasants began to use water power to run the grain mills and sawmills. They gained land for farming by clearing forests and draining swamps.

For the first time since the days of the Roman Empire, Europeans took notice of the world beyond their borders. Merchants traveled afar to trade with the peoples of the Byzantine Empire in southeastern Europe. The Crusades, a series of Christian military expeditions against the Muslims, encouraged European trade with

the Middle East (see Crusades). Italians in Genoa, Pisa, Venice, and other towns built great fleets of ships to carry the merchants' goods across the Mediterranean Sea to trade centers in Spain and northern Africa. The Italians brought back goods from these seaports. Many of the goods were exports from cities in India and China. Leaders in the towns of northern Germany created the Hanseatic League to organize trade in northern Europe.

Merchants exchanged their goods at great international trade fairs held in towns along the main European trade routes. Each fair was held at a different time of the year, and merchants traveled from fair to fair. The county of Champagne in northeastern France was the site of the first great European fairs. Its towns lay on the trade routes that linked Italy with northern Europe. Flemish merchants brought woolen cloth to the fairs. Italian merchants brought silks, spices, and perfumes from the Middle East, India, and China. Merchants from northern and eastern Europe brought furs, lumber, and stone. The merchants not only traded their goods, but also exchanged ideas about new methods of farming, new industries, and events in Europe and the rest of the world.

Medieval towns. Early towns were only small settlements outside the walls of a castle or a church. As towns grew larger, walls were built around them. Soldiers on the walls kept a lookout for attacking armies. The towns became crowded because the walls limited the amount of land available. Houses stood crowded together. The people had to build upward because land was expensive. Many buildings were five or six stories high.

Streets were narrow, crooked, dark, and filthy. Until about 1200, they were not paved. The people threw all their garbage and rubbish into the streets, and disease spread quickly. During the 1200's, people in some towns began to pave their streets with rough cobblestones. They also took some steps toward increasing sanitation.

A citizen who went out at night took his servants along for protection against robbers. The servants carried lanterns and torches because no town had street lighting. The wide use of lamps, torches, and candles made fire one of the great dangers for a medieval town. Wealthy citizens had stone and brick houses, but most houses were made of wood. A large fire was likely to wipe out a whole town. The city of Rouen, in France, burned to the ground six times between 1200 and 1225.

After the merchants and craftworkers settled in the towns, they set up organizations called *guilds.* A guild protected its members against unfair business practices, established prices and wages, and settled disputes between workers and employers.

Guilds played an important part in town government. When the first guilds were organized, towns had few laws to protect merchants or craftworkers. Most laws were made and enforced by the lord who owned the land on which a town stood. As the townspeople gained power, they demanded the right to govern themselves. Often, a guild forced a lord to grant the people a charter giving them certain rights of self-government. Guilds led the fight for self-government, and so members of guilds often ran the new town governments. See Guild.

The decline of feudalism. Economic recovery brought many changes to the social and political organization of Europe. Money came back into use with the growth of trade and industry, the rise of towns, and the Crusades. The manorial system began to break down as people grew less dependent on the land. Many peasants ran away from the manors to the towns. Other peasants bought their freedom with money they earned by selling food to the townspeople. The lords of some towns encouraged new settlers to come. Many lords granted freedom to peasants who settled in their towns.

The feudal system, based on manorialism, began to break down, too. Ruling lords could pay for military and political service with money instead of fiefs. Their wealth provided better pay for soldiers and officials they hired. In return, the lords received better service. They and their governments grew increasingly powerful.

Developments in the 1100's and 1200's laid the foundation for the eventual rise of great nation-states in England and France. Such powerful kings as Henry II of England and Louis IX of France forced feudal lords to accept their authority. These kings developed new and more centralized forms of government. They also organized national armies to protect the people, and established royal laws and courts to provide justice throughout the land (see Henry II [of England]; Louis IX). At the same time, small but well-organized governments took form in Flanders and Italian city-states, including Florence, Genoa, Siena, and Venice.

Learning and the arts during the High Middle Ages were devoted to glorifying God and strengthening the power of the church. From 1100 to 1300, almost all the great ideas and artistic achievements reflected the influence of the church.

Princes and laborers alike contributed money to build magnificent stone cathedrals that rose above medieval towns. Stained glass windows and sculptured figures that decorated the cathedrals portrayed events in the life of Christ and other stories from the Bible. The cathedrals still standing in the French cities of Chartres, Reims, Amiens, and Paris are reminders of the faith of medieval people. See Notre Dame, Cathedral of; Reims (picture).

Increasing contact with Arab and Byzantine civilizations brought back much learning that had been lost to Europe since the end of the Roman Empire. Scholars translated Greek and Arabic writings from these civilizations into Latin, and studied their meanings. More and more scholars became familiar with the writings of the Greek philosopher Aristotle. The scholars argued whether Aristotle's teachings opposed those of the church. A field of thought called *scholasticism* grew out of their discussions and writings (see Scholasticism). Among the great teachers and writers of this period were Peter Abelard, Saint Albertus Magnus, and Saint Thomas Aquinas (see Abelard, Peter; Albertus Magnus, Saint; Aquinas, Saint Thomas).

Students gathered at the cathedrals where the scholars lectured. Students and scholars formed organizations called *universities,* which were similar to the craftworkers' guilds. From the universities came men to serve the church and the new states, to practice law and medicine, to write literature, and to educate others.

The late Middle Ages

Between 1300 and 1500, medieval Europe gradually gave way to modern Europe. During this period, the Middle Ages overlapped the period in European history called the *Renaissance.* For a discussion of the great de-

Illumination (1200's) from a French manuscript; © Pierpont Morgan Library, New York City

Building a medieval stone wall required great engineering skill. In this illustration, workers cut stone into squares and carry it to a crane. A man powers the crane by walking on the steps of a large moving wheel. Another worker carries mortar up a ladder to the man who cements the pieces of stone together.

velopments in art and learning during this period, see the *World Book* article on **Renaissance**.

A halt in progress. Although art and learning advanced, other areas of medieval civilization stood still or fell back. Europe had moved forward economically and socially almost without interruption during the High Middle Ages. The population had grown steadily, social conditions had improved, and industry and trade had expanded greatly. These developments came to an end in the 1300's. The population decreased, the people became discontented, and industry and trade shrank.

Around 1300, slight climate changes made weather in western Europe cooler and wetter. As a result, the agricultural practices that had developed in Europe could not sustain the increased population. Famines and floods caused widespread hardship. An outbreak of plague, later called the Black Death, began in 1347 and killed a fourth to a half of Europe's people. See **Plague**.

The reduction in population due to famines, disease, and the plague had various social and economic consequences. Because of a labor shortage, lords tried to enact strict laws to keep peasants on their land and subject to high rents and other traditional obligations. Peasants rose in bloody revolts. In the towns, workers fought the rich merchants who kept them poor and powerless.

War also played a part in the slowdown of European progress. From 1337 to 1453, England and France fought the Hundred Years' War. This conflict interrupted trade and exhausted the economies of both nations (see **Hundred Years' War**). In addition, the breakdown of feudalism and manorialism caused civil war in most of Europe.

The growth of royal power. By the 1300's, the breakdown of feudalism had seriously weakened the feudal lords. At the same time, economic recovery had enriched the kings. With the help of hired armies, the kings enforced their authority over the lords. Royal infantry—newly armed with longbows, spears called *pikes,* and guns—defeated armies of feudal knights.

Meanwhile, kings greatly increased their power by gaining the support of the middle classes in the towns. The townspeople agreed to pay taxes to the kings in return for peace and good government. These developments gave birth to the nations of modern Europe.

Troubles in the church. The power of popes grew with that of kings, and bitter disputes arose between the rulers of church and state. Church leaders took an increasing part in political affairs, and kings interfered in church affairs more often. The popes sometimes surrendered their independence and gave in to the kings. This happened especially from 1309 to 1377, when the popes ruled the church from Avignon, France, instead of Rome. After the popes returned to Rome, disputes over the election of popes divided the church. Two, and sometimes three, men claimed the title of pope at once. Such disputes hurt the church's influence. They also caused criticism of church affairs and church teaching. Groups of people who challenged the church's authority won many followers. The church tried to root out such opposition. Western Europe's religious unity weakened, leading to the Protestant Reformation of the 1500's. See **Christianity** (The division of the church); **Inquisition**; **Pope** (The troubles of the papacy); **Reformation**.

The growth of humanism. In the late Middle Ages, scholars and artists were less concerned with religious thinking and focused more on understanding people and the world. This new outlook was called *humanism.*

The scholars and artists of ancient Greece and Rome had emphasized the study of humanity. Scholars and artists of the late Middle Ages rediscovered the ancient works and gained inspiration from them. Architects began to design nonreligious buildings rather than cathedrals. Painters and sculptors began to glorify people and nature in their works. Scholars delighted in the study of pre-Christian authors of ancient times. During the late Middle Ages, more and more writers composed prose and poetry not in Latin but in the *vernacular* (native languages), including French and Italian. This increasing use of the vernacular opened a new literary age and gradually brought learning and literature to the common people. Finally, the introduction of the printing press in Europe in the 1450's meant that books and documents could be made more cheaply. Thus, books became available for many more people to read.

The political, economic, and cultural changes of the late Middle Ages gradually changed Europe, and by the early 1500's, Europe was no longer medieval. But the culture and institutions of the Middle Ages continued to influence modern European history.

Middle America is a term geographers sometimes use for the area between the United States and South America. Middle America includes Mexico, Central America, and the islands in the Caribbean Sea. These islands are called the West Indies. Spanish is the dominant language in Middle America. For more information, see the *World Book* articles on each country in Middle America. The term *Middle America* is sometimes also used to refer to the Midwestern United States or to the U.S. middle class. See also **Caribbean Sea; Central America; West Indies.** Roderic A. Camp

Middle Atlantic States are New Jersey, New York, and Pennsylvania. For information on this region, see United States (Regions). See also the articles on the states that make up the region.

Middle class is a group of people between the upper and lower classes in a society. Many people in the middle class share similar levels of education, income, wealth, and power. For example, the majority of middle-class people have at least a high-school education and a comfortable standard of living. People in the middle class work for a living and do not inherit great wealth, but they can hold almost any occupation. People who consider themselves middle class often share certain personality traits, too, such as individualism, self-motivation, industriousness, and strict moral standards.

The term *middle class* came into use in the towns of Europe in the early 1800's. It referred to the *bourgeoisie* (business class), a group of people who had jobs that enabled them to live more comfortably than laborers, but not as well as aristocrats. Karl Marx, a German writer and thinker in the 1800's, helped define the differences between classes. Marx believed that people were divided into classes based on their access to the *means of production* (ways of making a living), such as land and machinery. As the economies of Europe became more industrialized, more people were needed to operate machinery in factories and to manage other workers. This growing demand for managers caused the middle class to expand. During the late 1800's and the 1900's, the middle class grew steadily with the addition of new groups, such as lawyers, accountants, health and welfare professionals, and specialists in information processing.

Today, most people in Western democracies view themselves as members of the middle class, regardless of their income. Because so many people describe themselves as belonging to the middle class, it has become an important segment of society. In many democratic countries, political candidates who capture the attention of the middle class gain wide support. For this reason, middle-class values and interests often shape national policies and world events. Graeme Morton

Ways of life in the Middle East range from modern cities to traditional farms. The city scene above shows a square in Istanbul, Turkey, dominated by a huge *mosque*—an Islamic house of worship. The farming scene shows traditional farming methods being used in southern Lebanon.

Middle East

Middle East is a large region that covers parts of northern Africa, southwestern Asia, and southeastern Europe. Scholars disagree on which countries make up the Middle East. But many say the region consists of Bahrain, Cyprus, Egypt, Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, Sudan, Syria, Turkey, United Arab Emirates, and Yemen. These countries cover about 3,743,000 square miles (9,694,000 square kilometers) and together have a population of about 262 million.

Two of the world's first great civilizations—those of Sumer and Egypt—developed in the area after 3500 B.C. The region also is the birthplace of three major religions—Judaism, Christianity, and Islam.

Since the birth of Islam in the A.D. 600's, Islamic powers have dominated the Middle East. More than 90 per cent of the region's people are Muslims—followers of Islam.

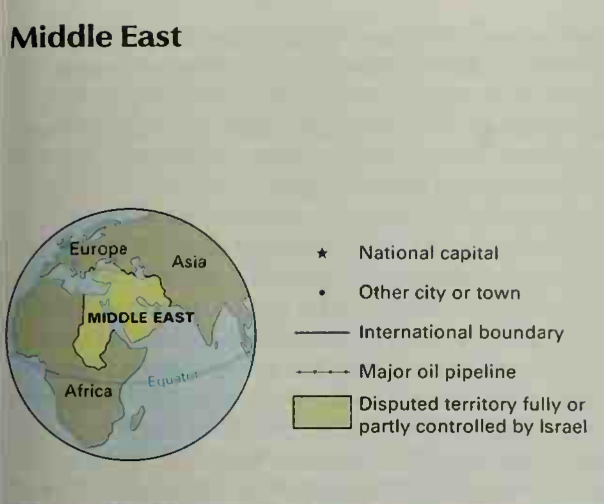
Most of the people of the Middle East are Muslim Arabs. Other religious and ethnic groups include black Africans, Armenians, Copts, Greeks, Iranians, Jews, Kurds, and Turks.

The Middle East is an area of great economic importance as one of the world's major oil-producing regions. It is also a scene of much political unrest and conflict.

People

Ancestry. The people of the Middle East belong to various ethnic groups, which are based largely on culture, language, and history. Ethnically, more than three-fourths of the Middle Eastern people are Arabs. Although they live in different countries, the Arabs share a common culture and a common language, Arabic. Iranians and Turks also form major ethnic groups in the region. Smaller groups in the Middle East include Armenians, Copts, Greeks, Jews, Kurds, and various black African groups.

Way of life. Until the 1900's, most Middle Eastern people lived in villages or small towns and made a living by farming. Only a small number lived in cities. Since World War II (1939-1945), many people have moved to urban areas. Today, in most Middle Eastern countries, more than half the people live in cities. Middle Eastern people have strong ties to their families and to their religious and language groups.



In general, city dwellers in the Middle East have a more modern way of life than the rural villagers. In the cities, cars and people move about at a fast pace. People hold jobs in business, education, government, and the media. Television, which is widely viewed, introduces Western ideas and tastes.

In rural areas of the Middle East, the way of life is slowly changing. Better fertilizers, irrigation methods, and machinery have made life easier for some farmers. But many Middle Eastern farmers still use the same kinds of tools and methods their ancestors used hundreds of years ago. Some people of the Middle East are nomads. They live in the desert and herd cattle, goats, and sheep.

Since the mid-1900's, changes have occurred in the status of urban women in the Middle East. Women in rural areas have always done farm work alongside their husbands, but most urban women were confined to their home. Today, many women in the cities have jobs in business, education, and government. For more information on the people of the Middle East, see the *People* section of the various country articles.

Oil is the Middle East's most important mineral product. These workers at Port Rashid in the United Arab Emirates are loading barrels of oil onto oil tankers.

Religion and language. The Middle East is the birthplace of Judaism, Christianity, and Islam. More than 90 percent of the area's population, including most Arabs, Iranians, and Turks, are Muslims. Christians make up about 7 percent of the population. The largest Christian groups are the Coptic, Melkite, and Maronite denominations. Jews, who make up only 1 percent of the population, live in Israel.

The chief language of the Middle East is Arabic. Written Arabic is the same throughout the region, but the spoken language differs from country to country. Persian is the official language of Iran. People in Turkey speak Turkish. Most Israelis speak Hebrew. Other languages of the Middle East include Baluchi, Greek, and Kurdish.

The land

In the northern part of the Middle East, mountains border interior plateaus. The Pontic Mountains and the Taurus Mountains rise in Turkey, and the Elburz and Zagros mountains extend across Iran.

The southern part of the Middle East is a vast arid plateau. Several large deserts lie in this area. The Western and Eastern deserts of Egypt are part of the Sahara. The Rub al Khali, known in English as the Empty Quarter, stretches across southern Saudi Arabia.

The Middle East has two major river systems—the Tigris-Euphrates and the Nile. The Tigris and Euphrates begin in the mountains of Turkey and flow through Syria and Iraq. In Iraq, the rivers meet and form the Shatt al Arab, which empties into the Persian Gulf. The Nile flows north through Sudan and Egypt to the Mediterranean Sea.

Economy

Agriculture has long been the Middle East's most important economic activity. More than half the people are farmers. But the discovery of oil in the Middle East in the early 1900's radically changed the economy of some countries. Oil production became a major industry. Manufacturing increased, particularly the manufacture of products made from oil. In some countries, especially Egypt, tourism is a major industry.

Agriculture. The chief crops of the Middle East include barley, cotton, oranges, sugar cane, tobacco, and wheat. Many Middle Eastern farmers do not own their land. But since World War II, a growing number have become owners of the small farms they work. In such countries as Egypt and Iraq, the amount of farmland has doubled since the late 1800's. The use of fertilizers, improved equipment, and better irrigation methods have helped bring about the increase. But many farmers continue to use traditional machinery and methods. They cannot afford tractors and other heavy equipment.

Mining. Oil is by far the most important mineral product of the Middle East. The region has about three-fifths of the world's known oil reserves. The major oil producers are Iran, Iraq, Kuwait, Oman, Qatar, Saudi Arabia, and the United Arab Emirates. Most of the oil is sold to European countries and Japan. The governments of the oil-producing countries use much of the income from oil sales to build roads, develop new industries, and provide services for their people.

In 1960, some oil-producing countries formed the Organization of Petroleum Exporting Countries (OPEC) to gain more control over oil prices. During the Arab-Israeli War of 1973, some Arab members of OPEC stopped or reduced oil shipments to countries supporting Israel. Prices of oil in those countries rose sharply.

Other minerals mined in the Middle East include coal, iron ore, and phosphates. Coal mines operate in Iran and Turkey. Egypt and Turkey produce iron ore. Jordan supplies a fifth of the world's phosphates.

Manufacturing. The major manufacturing countries of the Middle East are Egypt, Iran, and Turkey. Together, these three countries produce 6 percent of the world's refined sugar and 5 percent of its cement and cotton cloth. The Middle East also produces small amounts of fertilizers, paper, and steel. Israel manufactures a variety of specialized technological products, such as computer parts and fighter aircraft. In the late 1960's, the oil-producing countries began to develop industries that make use of oil. These industries include the manufacture of chemicals and plastics.

History

Early civilizations. People lived in parts of the Middle East as early as 25,000 B.C. It was in this region that agriculture began around 8000 B.C. Between 3500 and 3100 B.C., two of the world's earliest great civilizations—those of Sumer and Egypt—developed in the region. The Sumerian civilization developed on the fertile plain between the Tigris and Euphrates rivers (see **Sumer**). It was later absorbed by the Babylonian Empire. The Egyptian civilization arose in the Nile Valley (see **Egypt, Ancient**). About 1900 B.C., a people called the Hittites came to power in what is now Turkey. Other peoples, such as the Hebrews and the Phoenicians, also organized societies in the region.

Beginning in the 800's B.C., a series of invaders conquered these civilizations. The invaders included the As-

syrians, the Medes, the Persians, and, finally, Alexander the Great. Alexander conquered the Middle East in 331 B.C. and united it into one empire. He died in 323 B.C. The next 300 years, called the *Hellenistic Age,* brought great achievements in scholarship, science, and the arts.

By 30 B.C., the Romans had conquered much of the Middle East. During Roman rule, Jesus Christ was born in Bethlehem and died in Jerusalem. Christianity spread throughout the Roman Empire, replacing pagan cults. Christianity was the major religion of the Middle East until the rise of Islam in the A.D. 600's.

Islamic empires. Muhammad, the founder of Islam, was born in Mecca in about 570. In 622, he moved to the oasis of Medina, where he became the head of a small religious and political community. After his death in 632, his followers, called Muslims, conquered what are now Egypt, Iraq, and Syria. Many of the conquered people adopted Islam and the Arabic language. By 711, Arab Muslim rule extended from what is now Spain in the west to Iran in the east. Muslims of the Umayyad family ruled these lands from the city of Damascus. In 750, the Abbasid family overthrew the Umayyads and made Baghdad the capital of the Islamic Empire.

During Abbasid rule, groups of Muslim Turks invaded from central Asia. The most important were the Seljuk Turks. They took over Baghdad in 1055, and soon after, they conquered what are now Syria and Palestine. By the end of the 1000's, the Abbasid Empire was declining, and independent dynasties were emerging. In 1258, Mongols from China conquered Baghdad and destroyed the remains of the Abbasid government.

In the 1300's, the *dynasty* (family of rulers) of the Ottoman Turks became established in Anatolia (now Turkey). In the early 1500's the Ottomans added the Arab lands of the Middle East to their empire. By that time, they had also advanced into the Balkan Peninsula and had become a military threat to Europe. In the 1700's and 1800's, the Ottoman Empire declined in power and size in the face of new, strong states that developed in Europe. By World War I (1914-1918), some European countries had gained much economic and political influence in the Middle East.

World War I. During World War I, the Ottoman Empire joined with Germany against Great Britain, France, Italy, and Russia. Arabs who hoped to win independence from the Ottoman Turks supported the European Allies. Britain promised to help create independent Arab governments in the Middle East after the war. But Britain also agreed with France to divide the Middle East into zones of British and French rule and influence. In 1917, Britain issued the Balfour Declaration, which supported the creation of a Jewish homeland in Palestine—but without violating the civil or religious rights of the Arabs there (see **Balfour Declaration**).

In 1923, the defeated Ottoman Empire became the Republic of Turkey. The League of Nations divided most of the Arab lands of the Middle East into mandated territories (see **Mandated territory**). France took control of Lebanon and Syria. Britain received the mandates for Iraq, Jordan (called Trans-Jordan until 1949), and Palestine. Britain also kept control over Egypt, which it had conquered in 1882. The Arabs conducted a struggle for independence in the years after the war. Many territories gained independence in the 1930's and 1940's.

Palestine. In Palestine, Arab mistrust of Great Britain grew during the 1930's. Between 1933 and 1935, more than 100,000 Jewish refugees fled to Palestine from Nazi Germany and Poland. The Jewish immigration alarmed the Palestinian Arabs, who wanted Palestine to become an independent Arab state. In 1936, they called a general strike that almost paralyzed Palestine. They declared the strike would last until the British halted Jewish immigration. But after about five months, the Arabs ended the strike without achieving their goals. However, they continued to oppose British control.

In 1947, Great Britain asked the United Nations (UN) to deal with the Palestine problem. The UN voted to divide Palestine into two states, one Arab and one Jewish. The Jews accepted this solution and established the State of Israel on May 14, 1948. The Arabs, who made up about two-thirds of the population of Palestine, rejected the plan. The next day, five Arab states—Egypt, Jordan, Iraq, Lebanon, and Syria—attacked Israel. The Israelis defeated the Arabs.

When the war ended in 1949, Israel had about half the land that the UN had assigned to the Arab state. Egypt controlled the Gaza Strip, and Jordan occupied and later annexed the West Bank of the Jordan River. The city of Jerusalem was divided between Israel and Jordan. About 700,000 Palestinian Arabs had fled or been driven out of the land that was now Israel. They became refugees in Gaza, the West Bank, Syria, and Lebanon.

Continuing conflict. The 1950's and 1960's were years of radical change in the Middle East. A new generation led by young army officers took over the governments of many Arab states. They overthrew leaders who had cooperated with Great Britain and France. They hoped to bring about a political unification of the Arab world and to remove any European influence. Gamal Abdel Nasser, the leader of Egypt, became the symbol of these hopes. In 1956, Nasser seized the Suez Canal in Egypt from its British and French owners. In response to Nasser's action, Britain, France, and Israel invaded Egypt. Pressure from the United States, the Soviet Union, and other nations forced the invaders to withdraw.

In May 1967, the Arabs believed Israel was planning a major attack on Syria. Nasser sent Egyptian troops into the Sinai Peninsula and closed the Straits of Tiran, the entrance to the Israeli port of Elat. On June 5, the Israeli air force retaliated by destroying most of the air forces of Egypt, Syria, and Jordan. In the following six days, Israel seized the Sinai Peninsula and the Gaza Strip from Egypt, the Golan Heights from Syria, and the West Bank (including East Jerusalem) from Jordan. Almost 1 million Palestinian Arabs came under Israeli rule.

After the Six-Day War, no solution was reached in the Arab-Israeli conflict. The Arabs wanted Israel to withdraw from the land it had conquered. Israel demanded negotiations and Arab recognition of its right to exist.

The Palestine Liberation Organization (PLO), founded in 1964, became an important force in the Middle East after the 1967 war. The PLO is a confederation of Palestinian Arab groups that wants to establish an Arab state in Palestine. It includes associations of lawyers, teachers, laborers, and other groups, as well as guerrilla fighters who staged terrorist attacks and commando raids against Israel. The Arab nations recognized the PLO as the representative of the Palestinian people.

AP/Wide World

A historic agreement between Israel and the Palestine Liberation Organization (PLO) was signed on Sept. 13, 1993, in Washington, D.C. The two bitter enemies agreed to work to end their conflicts. Following the signing, Israeli Prime Minister Yitzhak Rabin, *far left,* and PLO leader Yasir Arafat, *near left,* shook hands as United States President Bill Clinton looked on.

In October 1973, Egypt and Syria launched a surprise attack against Israel. They were driven back by the Israelis. Most of the fighting ended by November.

Attempt at peace. In 1977, Egyptian President Anwar el-Sadat declared his willingness to make peace. In 1978, Sadat, Israeli Prime Minister Menachem Begin, and U.S. President Jimmy Carter held discussions at Camp David in the United States. The discussions resulted in an agreement called the Camp David Accords. Israel agreed to withdraw from Egypt's Sinai Peninsula. Egypt and Israel pledged to negotiate with Jordan and the Palestinians to grant some form of self-rule to the West Bank and the Gaza Strip. Egypt and Israel signed a peace treaty in 1979, and Israel withdrew from the Sinai. But no immediate progress was made in deciding the future of the Gaza Strip and the West Bank.

More conflict. In the 1970's in Lebanon, an uneasy balance between the Muslim and Christian communities collapsed. The conflict was sparked by the presence of armed PLO members in the country. The Muslims supported the PLO fighters, and the Christians opposed them. But at the heart of the conflict was the fact that Lebanon's growing Muslim population demanded more power in the government. The Christians opposed Muslim demands for increased power. In 1975, civil war broke out between various Muslim and Christian forces. Most of the fighting in Lebanon ended in 1991.

A revolution occurred in Iran in 1979. Muslim religious leader Ayatollah Ruhollah Khomeini and his followers took control of the government. Khomeini declared Iran to be an Islamic republic. From 1980 until 1988, Iran and Iraq fought a war over territorial disputes and other disagreements.

The Arab-Israeli conflict flared up again at the end of 1987. Arabs in the Gaza Strip and the West Bank began demonstrating against Israel's occupation. Violence erupted between Israeli troops and the demonstrators.

In August 1990, Iraq invaded Kuwait. The United States and other nations sent military forces to Saudi Arabia to defend that country against a possible Iraqi invasion. These nations and Saudi Arabia formed an allied military coalition. In January 1991, war broke out between Iraq and these nations. In February, the allied coalition defeated Iraq and forced its troops to leave Kuwait. For more information, see **Persian Gulf War**.

Recent developments. In October 1991, a peace conference began between Israel on one side, and Middle Eastern Arab nations and Arab residents of the Gaza Strip and the West Bank on the other. In separate talks in 1993, Israel and the PLO agreed to recognize each other.

Beginning in 1993, Israel and the PLO signed several agreements that led to the withdrawal of Israeli troops from the Gaza Strip and portions of the West Bank. As the Israelis withdrew, Palestinians took control of these areas. In 1996, Palestinians in these areas elected a legislature and a president.

In 1994, Israel and Jordan signed a peace treaty. This treaty formally ended the state of war that had technically existed between the two countries since 1948.

In 2000, peace talks between Israeli and Palestinian leaders failed to produce a final peace settlement. That same year, violence broke out between Palestinian protesters and Israeli troops in Jerusalem, the West Bank, and the Gaza Strip.

Middle school is a school designed for students in sixth, seventh, and eighth grade. Some middle schools include fifth grade. In a number of communities, students attend middle school rather than junior high school. Middle schools are sometimes called *intermediate schools.*

Middle schools try to meet the special needs of children of the sixth, seventh, and eighth grades. Most children of this age are entering *puberty.* This period of rapid growth marks the end of childhood and the start of physical and sexual maturity. Middle schools try to help students understand the physical and social changes of puberty.

Many middle schools use a method of instruction called *individualized learning,* also called *individualized instruction.* This system enables each student to advance at his or her own speed and receive individual help from the teacher. The schools also use *team teaching,* in which several teachers share the responsibility for teaching a group of students.

Middle schools began in the United States about 1960 and their number has increased steadily. In the 1960's, many schools became overcrowded. To relieve the crowded conditions, some communities built middle schools. Donald H. Eichhorn

Middleton, Arthur (1742-1787), was a South Carolina signer of the Declaration of Independence. He was a leader in the Revolutionary War in America (1775-1783).

Between 1765 and 1776, Middleton served in the colonial legislature and in the Provincial Congress of South Carolina. While in the congress, he helped write South Carolina's Constitution of 1776. Middleton also served as a member of the first South Carolina Council of Safety, which provided transitional government after the colonial government was overthrown. He was a delegate to the Continental Congress in 1776 and 1777 and to the Congress of the Confederation in 1781. The British captured him in 1780 at the siege of Charleston, South Carolina. Middleton was born near that city.

Robert A. Becker

Midge is any of a large family of small flies. Midges look like tiny mosquitoes, but they do not bite. There are about 2,000 species of midges, about 670 of which live in North America. Midges have slender bodies and long, thin legs. Adult males have feathery antennae. These insects often appear at dusk in large numbers that look like a moving haze.

The *larva* (immature form) of a midge resembles a worm. It may be green, white, or red. Red larvae are often called *bloodworms.* Midge larvae are found in mud, in water, or on decaying plant matter. They are a major source of food for larger insects and fish.

Several families of flies that have the word *midge* as part of their name are not really midges. These include the biting midges, also known as *punkies* or *no-see-ums.* Biting midges have stout bodies and a painful bite. They are seen near lakes and rivers and at the beach. Some people call biting midges *sand flies* (see Sand fly).

A common midge

Scientific classification. Midges belong to the midge family, Chironomidae. Biting midges make up the biting midge family, Ceratopogonidae.

Midget. See Dwarf.

Midnight sun is a term used for the sun when it can be seen 24 hours a day in the earth's polar regions. At the North Pole, the sun never sets for six months, from about March 20 to September 23. At the South Pole, the sun remains above the horizon from about September 23 to March 20. The length of periods of continuous

WORLD BOOK graphs

The midnight sun provides continuous sunlight on the Arctic Circle for a few days around June 21. In the illustration at the left, both the Arctic Circle and the United States are in sunlight. In the illustration at the right, the rotation of the earth has turned the United States away from the sun into darkness, but the Arctic Circle remains in sunlight.

sunlight decreases as the distance from either pole increases. At an imaginary line called the Arctic Circle, such a period occurs for only a few days around June 21. At another imaginary line, the Antarctic Circle, it lasts for a day or two around December 21.

The midnight sun is caused by the tilting of the earth's axis in one direction as the earth travels around the sun. One pole slants toward the sun for six months, while the other pole slants away from the sun and receives no sunlight. As the earth revolves around the sun, it also spins on its axis. This spinning motion makes the sun appear to rise and set at regular intervals, causing day and night on most of the earth. C. R. O'Dell

Midway, Battle of. See World War II (The tide turns); Midway Island.

Midway Island lies 1,300 miles (2,090 kilometers) northwest of Honolulu in the Pacific Ocean. It is made up of two islands in an atoll 6 miles (10 kilometers) in diameter. It has an area of 2 square miles (5 square kilometers) and a total coastline of about 20 miles (32 kilometers). Midway has a population of about 470. The United States discovered Midway in 1859, and annexed it in 1867. United States companies built a cable relay station there in 1903, and an airport in 1935. The U.S. Department of the Interior controls the island.

The Battle of Midway was one of the main naval battles in World War II. From June 4 to June 6, 1942, U.S. land- and carrier-based planes attacked a Japanese fleet approaching the islands. They sank four aircraft carriers and one heavy cruiser. The United States lost the destroyer *Hammann* and the aircraft carrier *Yorktown.*

The Battle of Midway was the first decisive U.S. naval victory over the Japanese in World War II. It crippled Japan's naval air power and ended Japan's attempt to seize Midway as a base from which to strike Hawaii. Many military experts believe it was the turning point in the Pacific campaign. Robert C. Kiste

See also World War II (The tide turns).

Midwestern States are Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin. For information on these states, see **United States** (Regions) and the articles on the states that make up the region.

Midwife is a person who helps women give birth. A midwife also gives care and advice during the patient's pregnancy and after the baby is born. Midwives work in birthing centers, patients' homes, and hospitals.

In the United States, trained midwives are called *nurse-midwives.* They are registered nurses who have been certified by the American College of Nurse-Midwives. Some states require nurse-midwives to have a special license. Other states allow them to practice under their nursing license.

Nurse-midwives emphasize that childbirth is a natural, normal process. They help the family have a safe and satisfying birth experience. Most nurse-midwives accept only patients who will probably have a normal delivery. However, they must be able to recognize signs of difficulty during childbirth. If necessary, a physician is called, or the patient is moved to a hospital.

Lay midwives have no formal training in midwifery. Traditionally, most lay midwives have worked in rural areas that have relatively few doctors. A few states license lay midwives, but lay midwifery is illegal in most states. Lois Kazmier Halstead

Midwife toad is the name of certain small frogs of central and southwestern Europe. Midwife toads are also called *obstetrical toads.* They received their name because the male helps care for the eggs. Adult midwife toads are about 2 inches (5 centimeters) long. The female lays from 20 to 60 eggs in two strings. The male fastens them to his legs and carries them until they hatch. He usually hides on land beneath a stone or underground while he carries the eggs. He comes out after dark and bathes the eggs in a pond or stream. After three weeks he takes the eggs into the water, and tadpoles hatch from them. J. Whitfield Gibbons

J. Andrada, Bruce Coleman Ltd.

The male midwife toad carries the fertilized eggs like a bunch of grapes attached to its hind legs until the tadpoles hatch.

Scientific classification. Midwife toads belong to the family Discoglossidae. The most common species is *Alytes obstetricans.*

Mies van der Rohe, *MEEZ van duhr ROH uh,* **Ludwig** (1886-1969), was one of the most influential architects of the 1900's. He won fame for the clean, uncluttered design of his buildings of brick, steel, and glass. His architectural philosophy is sometimes summarized by the phrase "less is more."

Mies, as he was called, was born in Aachen, Germany. He built his first steel-framed building in 1927 at the Werkbund exposition he directed in Stuttgart, Germany. Two years later, he built his famous German Pavilion at an international exhibition in Barcelona, Spain. It featured onyx partition walls, a hovering slab roof, and travertine walls. The building enclosed space in an abstract manner through its asymmetrically placed wall elements that extended beyond the body of the building.

In 1930, Mies became director of the Bauhaus school of design in Dessau, Germany. That same year, he built the Tugendhat house in Brno, Czechoslovakia. This house applied his abstract principles of composition to domestic architecture. In 1932, Mies moved the Bauhaus to Berlin, where he remained until it closed in 1933.

Mies moved to the United States in 1938. He became director of the school of architecture, planning, and design at the Armour Institute in Chicago, later the Illinois Institute of Technology (IIT). In 1939, Mies began planning a new campus for IIT. He left the symmetrical steel skeletons of the buildings exposed and combined them with great expanses of glass and carefully arranged panels of brick (see **Architecture** [Ludwig Mies van der

Mifflin, Thomas (1744-1800), represented Pennsylvania at the Constitutional Convention of 1787 and signed the Constitution of the United States. Mifflin played only a minor role at the convention, seldom joining in debates. But he was highly popular in Pennsylvania and served the state throughout his life.

Mifflin was born on Jan. 10, 1744, in Philadelphia of Quaker parents. He was elected to the Pennsylvania Assembly in 1772 and became a member of the First Continental Congress in 1774. After the Revolutionary War in America began in 1775, he soon became quartermaster general of General George Washington's troops. Mifflin resigned from his post in 1777. About that time, he became involved in a plot to remove Washington as commander in chief. Mifflin then returned to the Pennsylvania Assembly, where he favored the interests of business. He served in the Congress of the Confederation from 1782 to 1784 and as chief executive of Pennsylvania from 1788 to 1799. Richard D. Brown

Mignonette, *MIHN yuh NEHT,* is an attractive garden plant of North America and Europe. Its name comes from a French word that means *little darling.* The mignonette has a low, bushy mass of smooth, soft-green leaves. The tiny flowers grow on tall spikes. The flowers are yellowish-white with reddish pollen stalks inside and have a delightful fragrance. Gardeners have produced larger-flowered mignonettes, but they are not as fragrant. Some cultivated varieties make excellent border plants. The plant grows best in a cool temperature and a light soil. It is a hardy plant that may be grown from seed plantings in May and July. Robert A. Kennedy

WORLD BOOK illustration by Robert Hynes

Mignonette

Scientific classification. The mignonette is in the mignonette family, Resedaceae. The plant is *Reseda odorata.*

Migraine is a type of headache that causes a severe, throbbing pain, often on only one side of the head. Some migraine patients have an experience called an *aura* before they feel pain. The most common auras involve visual disturbances, such as shimmering lights or blind spots. People with migraine often have nausea, vomiting, or extreme sensitivity to light or noises. From 50 to 80 percent of migraine sufferers have family members who also get migraines.

Doctors have found that many foods and activities can trigger migraines in people who tend to get these headaches. For example, alcoholic beverages and foods seasoned with a salt called *monosodium glutamate* may cause migraines for some people. Seeing bright lights or neglecting to eat may trigger headaches for others. Some patients can reduce the frequency of their migraines by identifying their particular triggers and avoiding those foods and experiences.

For many years, theories about the causes of migraine headaches focused on blood flow in the brain and changes in the size of the brain's arteries. Most physicians now believe that the disorder involves *serotonin,* an important messenger chemical in the brain. Among other roles, serotonin affects the movement of water and salts in and out of the walls of blood vessels in the brain.

Understanding serotonin's involvement in migraine led to development of *sumatriptan,* a drug chemically similar to serotonin. For many migraine patients, suma-

triptan can quickly stop head pain and such symptoms as nausea and vomiting. Side effects, though rare, include potentially serious heart conditions.

Migraines that are just beginning may also be stopped by drugs made from the fungus *ergot* (pronounced *UR guht*) that narrow blood vessels. Strong pain medication or drugs that fight nausea may be used for a headache that has firmly taken hold. Patients who often suffer migraines may regularly take medications that can reduce the frequency and severity of these headaches. Such drugs include *beta-blockers* and *calcium channel blockers.* Michael B. Stevens

See also **Beta-blocker; Calcium channel blocker; Ergot; Headache; Serotonin.**

Migrant labor is a farm labor force that moves into a region temporarily to help harvest and process crops. Migrants usually harvest fruits and vegetables that must be picked as soon as they ripen. Few of these workers settle permanently in any community. In the United States, most migrants are American Indians, blacks, Mexican Americans, Mexicans, or Puerto Ricans. No one knows how many migrants work in the United States. Estimates range from 125,000 to over a million.

Temporary farmworkers generally receive low wages and often cannot find continuous work. Many migrants do not work in one place long enough to qualify for such government aid as food stamps and disability insurance. They are not protected by federal laws concerning hours, wages, and union membership that cover industrial workers. Many migrant families live in run-down, unsanitary housing. They often lack adequate food or medical care, and many suffer malnutrition or other health problems.

Many migrant workers have difficulty finding other kinds of work because they lack education. Only about a fifth of the migrant children go beyond sixth grade. Migrant youngsters tend to fall behind in their education because they change schools frequently. Some migrant children miss classes because they work to help support their family. Many schools sponsor special programs to promote the education of migrant children who temporarily live in the area. The federal Comprehensive Employment and Training Act of 1973 provided vocational training for adult migrants.

During the late 1960's, the California labor leader Cesar Chavez organized what is now the United Farm Workers of America (UFW). Many farm operators opposed the union, which seeks higher pay for migrants. They believed that increased labor costs would result in smaller profits and higher food prices. By 1970, some growers had signed UFW contracts that provided wage increases. However, most migrants today are not protected by such contracts. Warren Van Tine

Migration, in biology, is the movement of animals to a place that offers better living conditions. Many kinds of animals regularly migrate to avoid unfavorable changes in weather or food supply, or to take advantage of better living conditions elsewhere. Human beings also migrate, but they do so for political and social reasons as well as biological ones. For information on human migrations, see **Immigration.**

Biologists use the term *migration* to describe several types of movements. Some biologists, particularly those who study insects, refer to one-way journeys as migrations. Such movements take place when animals leave an area in search of better living conditions, and neither they nor their descendants necessarily return to the original area. Other biologists refer to the long-term historical changes in the distribution of animals as migrations. But most biologists define migrations as regular, round-trip movements between two areas. Each area offers more favorable living conditions than the other at some point in the animals' lives. This article discusses such regular, round-trip migrations.

Migrations take place on land, in water, or in the air. Some animals migrate only short distances. For example, many frogs and toads make yearly migrations of only a few miles or kilometers between their breeding and nonbreeding homes. Other migrations cover thousands of miles or kilometers. Arctic terns rank among the animals that migrate farthest. These birds travel as much as 22,000 miles (35,400 kilometers) in a year.

Types of migrations. Most migratory animals make (1) daily migrations or (2) seasonal migrations. Other migratory animals make only one or a few round-trip journeys during their lifetime.

Daily migrations take place among many of the small, drifting animals that live in the ocean. These *zooplankton* swim hundreds of feet or meters below the surface during the day. Each night, they migrate to the upper levels of the water.

Seasonal migrations take place twice a year. They occur in connection with periodic changes in temperature or rainfall. There are three main kinds of seasonal migrations: (1) latitudinal migrations, (2) altitudinal migrations, and (3) local migrations.

Bats, seals, some whales, and most migratory birds perform *latitudinal migrations.* That is, they migrate in basically a north-south direction. Some mountain-dwelling animals make *altitudinal migrations* up and down the mountain slopes. For example, mountain quail and mule deer spend summer in high elevations and move to lower areas in winter. A large number of tropical birds and mammals make *local migrations.* They move to moister regions of the tropics during the dry season and return to their original homes when the rainy season begins.

Less frequent migrations are made by some animals. For example, salmon are born in freshwater streams but soon migrate to the oceans. After several years, they return to their freshwater birthplaces to breed. Pacific salmon die soon afterward, but some Atlantic salmon swim back to the ocean and return to their birthplaces to breed as many as three times. Female sea turtles also make migrations during their lifetime. Every two or three years, mature female green turtles and loggerhead turtles swim up to 1,400 miles (2,300 kilometers) to the beach where they hatched. There they lay their eggs.

Why animals migrate. Migration enables many species to take advantage of favorable weather and

abundant food supplies in areas with changing environments. In some parts of the world, for example, food is plentiful in summer but becomes scarce during the cold winter months. Many animals that live in these regions migrate to warmer climates in the fall. They return in the spring when the weather warms up.

Many migrations are related to reproduction. Numerous animals migrate to breeding areas where their young have the best chance for survival. Migratory birds breed in their summer homes, where the food supply is most abundant. Humpback whales, on the other hand, migrate from their polar feeding grounds to give birth in tropical or subtropical waters. The warm waters provide little food for the adults, but the newborns could not survive in the polar seas.

What triggers migrations. Many animals begin their migrations after unfavorable environmental conditions set in. But among other species, the factors that trigger migrations are more difficult to explain. Many migratory birds, for example, leave their winter homes in the tropics while conditions there are still favorable. Among such species, migration may be triggered by environmental changes that are associated with the onset of warm weather and increased food in their northern breeding grounds. Experiments show that changes in daylength stimulate the migrations of many species of birds. In spring, the increasing hours of daylight trigger the release of certain *hormones* in the bodies of the birds. Hormones are chemical substances that regulate many body functions. In this case, the hormones stimulate preparations for the northward trip.

Besides using environmental clues, many seasonal migrators probably have an inborn "calendar" that tells them when to migrate. Some birds show seasonal migratory behavior even when kept under constant conditions in a laboratory. An inborn timing mechanism may trigger the migration of salmon and other animals that migrate at different stages of their life.

How migrating animals find their way. Research has shown that animals use many ways to gather directional information during migrations. Many are guided by the sun, the moon, and the stars. Such travelers must be able to allow for the movements of these heavenly bodies in determining direction. Other animals follow such landscape features as rivers or mountain ranges.

Animals rely on more than visual cues when they migrate. Salmon find their way back to their birthplace by recognizing the odors of their home streams. Some animals are guided by changes in temperature, moisture, wind direction, or the earth's magnetic field. Sea dwellers may use information from ocean currents.

Many animals use more than one compass during their migrations. According to many biologists, some species of birds are guided by the sun and the earth's magnetic field during the day, and by the stars and the magnetic field at night. On cloudy days and nights, these birds may use the magnetic field alone to find their way.

Sometimes, migrating animals are forced from their normal route into an unfamiliar area. In some cases, the "lost" animals seem to be able to determine where they are and how to reach their original destination. This process is called *navigation.* Although there are many examples of what appears to be navigation by animals, scientists know little about how this process works.

Some of the most convincing evidence of animal navigation comes from experiments with shearwaters, sparrows, and homing pigeons. Scientists captured these birds and took them to unfamiliar areas up to thousands of miles or kilometers away. Most of the birds successfully returned to the original capture point.

Other experiments indicate that although young animals are able to migrate, they may not be able to navigate from unfamiliar areas. For example, European starlings normally migrate southwest from their breeding grounds around the Baltic Sea to wintering areas bordering the English Channel. Scientists captured adult and young starlings that had reached the Netherlands during a migration. They took the birds to Switzerland and released them. The adult starlings corrected for the move and reached their normal wintering grounds. But the young birds, which were on their first migration, continued to fly southwest and ended up in Portugal, Spain, and southern France. Sidney A. Gauthreaux, Jr.

Mikado, *muh KAH doh,* is a term once used to refer to the emperor of Japan. It comes from the Japanese words meaning *honorable gate,* which referred to the emperor's residence.

The term Mikado was more commonly used by Westerners than by the Japanese. It was popular in the 1800's among foreigners in Japan. In the late 1800's, the term became well known in Western countries through the operetta *The Mikado.* The comic opera, written by William S. Gilbert and Arthur S. Sullivan, is set in Japan. It tells the story of a Japanese girl who falls in love with the Mikado's son.

When referring to their emperor, the Japanese use the term *Tenno,* meaning *heavenly emperor.* They adopted the term from the Chinese during the reign of the Japanese Empress Suiko, who ruled from A.D. 592 to A.D. 628. Japanese emperors are not referred to by their personal name but by a reign name. For example, the current emperor, Akihito, is known as the *Heisei Tenno* or *Heisei Emperor.* Hitomi Tonomura

Mikan, *MY kuhn,* **George** (1924-), became the most famous—and perhaps the dominant—basketball player of the 1940's and early 1950's. In 1950, sportswriters selected Mikan as the outstanding college or professional player of the first half of the 1900's. Mikan, who stood 6 feet 10 inches (208 centimeters) tall, used his height, strength, and great hook shot to become the first of basketball's high-scoring centers.

George Lawrence Mikan was born in Joliet, Illinois. He played college basketball at DePaul University, where he won all-America honors in 1944, 1945, and 1946. Mikan starred with the Minneapolis Lakers profes-

sional team from 1947 to 1956. He led the Lakers to National Basketball Association (NBA) championships in the 1948-1949, 1949-1950, 1951-1952, 1952-1953, and 1953-1954 seasons. Mikan scored 11,764 points for the Lakers, an average of 22.6 points per game. Mikan led the league in scoring during the 1948-1949, 1949-1950, and 1950-1951 seasons. Bob Logan

Milan, *mih LAN* (pop. 1,369,231), is the second largest city in Italy. Only Rome has more people. Milan ranks as Italy's chief center of finance, manufacturing, and international trade. The city's location in northern Italy, near a pass through the Alps, made it a center of trade as early as the A.D. 100's (see **Italy** [political map]). Many tourists visit Milan to see the city's priceless works of art. Milan is the capital of Lombardy, one of the political regions of Italy. The city's name in Italian is Milano.

The city covers 70 square miles (182 square kilometers). Much of Milan has a modern appearance, but it also includes a number of beautiful ancient buildings.

Milan's large Gothic cathedral stands in the heart of the city, and the nearby area includes many cultural attractions. Music lovers from many parts of the world hear concerts at La Scala, one of the leading opera houses of Europe. The Ambrosian Library is a treasure house of rare books and ancient manuscripts. Masterpieces of Italian painting hang in the Brera Art Gallery, the Gallery of Modern Art, the Poldi Pezzoli Museum, and the Sforza Castle. The fortresslike castle once served as the home of Milan's rulers. Leonardo da Vinci painted *The Last Supper,* one of the most famous masterpieces in history, on a wall of the Monastery of Santa Maria delle Grazie. Visitors to Milan may see this painting, which appears in the **Jesus Christ** article.

Milan has several major universities, including Bocconi University, the Catholic University of the Sacred Heart, and the University of Milan. The city also has several technical institutes.

The 36-story Pirelli Building, one of the tallest business structures in Italy, stands in an area of modern office buildings in the northern part of Milan. Industrial areas and residential suburbs extend from the city in all directions. Like other modern cities, Milan has such problems as air pollution and traffic jams.

People of Milan are called Milanese. They have a reputation for ambition, energy, and skill in business. Many earn their living as management personnel with a business firm or as skilled workers.

Many Milanese like to spend afternoons at a cafe in the city, making business deals or chatting with friends. A favorite gathering place is the Galleria Vittorio Emanuele II, a large, glass-roofed building that includes restaurants and shops. The Galleria, often called the "living room of Milan," stands near the cathedral.

Economy. Milan is the site of Italy's stock market and the headquarters of its major banks. The Italian advertising, publishing, and design and fashion industries are also centered in the city. The Milan area has thousands of small and medium-sized factories and several huge manufacturing plants. Leading products of Milan include chemicals, electric appliances, textiles, tires, and transportation equipment. The city is a hub of major highways and railroad lines, and it has two major airports—Linate and Malpensa.

History. Around 400 B.C., the Celts, a people of western Europe, founded a town on the site of what is now Milan (see **Celts**). In 222 B.C., the Romans conquered the town, which they named Mediolanum. Mediolanum, later called Milan, became a Roman military base and also a center of trade between Rome and central Europe. By

Erika Stone from Peter Arnold

The Galleria in Milan is a large glass-roofed building that houses numerous restaurants and shops. The famous landmark is a popular meeting place of the people of Milan.

the A.D. 200's, it was one of the largest cities of the Roman Empire. Barbaric tribes invaded Milan and other parts of Europe in the 400's. The empire fell in 476. The invasions ended trade, and Milan became a small town.

The city regained importance in the 1000's as European trade and commerce expanded. From 1277 to 1535, Milanese nobles governed the city. They hired great artists who created beautiful buildings and works of art.

The Spanish Empire took over Milan in 1535, and Austria gained control of the city in 1714. French forces led by Napoleon conquered Milan in 1796, but Austria regained the city in 1815. Milan became part of the Kingdom of Sardinia in 1859 and part of the newly formed Kingdom of Italy in 1861. The city developed some of Italy's first modern industries in the late 1800's.

Benito Mussolini, who ruled Italy as dictator from 1922 to 1943, founded his Fascist movement in Milan in 1919. Allied bombings damaged large areas of Milan during World War II (1939-1945), but the people rebuilt their city. The 1950's and 1960's brought great industrial growth to Milan. Many people came from southern Italy to work in the city's factories. This increase in population led to a severe housing shortage. But in the 1960's and 1970's, the city helped finance the construction of hundreds of new apartment buildings. David I. Kertzer

For the monthly weather in Milan, see **Italy** (Climate). See also **Milan Cathedral**.

Milan Cathedral is a large church in Milan, Italy. It was begun in 1385 and is primarily Gothic in style. As construction continued for several centuries, the cathedral also has Renaissance and baroque ornament. It was completed in 1813 by the order of Napoleon I.

The cathedral is built of white Carrara marble in the plan of a Latin cross. It is 520 feet (158 meters) long and 205 feet (62 meters) wide. The cathedral is noted for its elaborate decoration, which includes marble spires each bearing a life-sized statue of a saint, Biblical character, or historical figure. There are more than 3,000 statues in the interior and exterior of the cathedral. The cathedral dominates a large public square in the center of the city. J. William Rudd

Ted Spiegel, Black Star

Milan Cathedral in Italy is one of Europe's largest churches. Its roof is covered with 135 marble spires, each bearing a statue.

Milan Decree was a fundamental step in the *Continental System,* a plan of French Emperor Napoleon I to destroy Britain by ending British trade with continental Europe. Napoleon issued the decree on Dec. 17, 1807.

The Milan Decree supplemented Napoleon's Berlin Decree of 1806, which had begun the Continental System. The Berlin Decree barred British ships from entering ports that were under French control. In early 1807, the British fought the Berlin Decree by issuing the *Orders in Council,* which required neutral ships to stop at British ports before sailing to ports controlled by France. The British loaded the ships with British goods before allowing them to proceed to the French-controlled ports. The Milan Decree said that France could seize any ship that obeyed the Orders in Council.

Although the Milan Decree increased the effectiveness of the Continental System, Napoleon could not adequately enforce it because the British had the most powerful navy afloat. But Napoleon did cause great distress to neutral powers. The decree led the United States to adopt severe acts to protect its commerce. Napoleon eventually convinced the United States that he would withdraw his decree. In this way, Napoleon turned American anger against the British and furnished a cause for the War of 1812 between the United States and Britain. Eric A. Arnold, Jr.

Mildew is the name of several kinds of fungi that attack plants and some products made from plants and animals. The name comes from a Middle English word, *mealdew,* meaning *spoiled meal.* There are two main classes that damage living plants: *powdery mildew* and *downy mildew.* The term *mildew* also can be applied generally to any fungus that grows in a damp place.

Powdery mildews attack green plants. There are about 50 different kinds of powdery mildews, and some of them can attack several different plants. About 1,500 different kinds of flowering plants may be infected by powdery mildew. These include the gooseberry, pea, peach, rose, apple, cherry, and grape.

Powdery mildew usually grows on the surface of the leaves, but it may also grow on the stems and fruits. The mildew forms white blotches that consist of many *hyphae* (threads). These hyphae send out branches that absorb nutrients from the cells of leaves, stems, or fruits. The hyphae also produce cells called *spores* by which the mildew reproduces. Certain *fungicides* (chemical solutions that kill fungi) can be used to protect plants.

Downy mildews produce yellow spots on the upper surfaces of the leaves or young fruits. After a mildew attacks the top of a leaf, small sporelike structures develop from the *stomata* (breathing pores) on the bottom of the leaf. These sporelike structures may produce even tinier spores that swim in the dewdrops on the surface of the leaf. Infections occur as these spores send hyphae into the leaf or fruit tissue.

Downy mildews attack many plants, including grape, cucumber, cabbage, onion, and lettuce. In 1845 , 1846, and 1848, a fungus that was related to downy mildew almost destroyed the Irish potato crop, and a terrible famine followed. One way to protect plants from downy mildew is to spray them with a copper-based fungicide such as *Bordeaux mixture.* In addition, scientists have developed disease-resistant plants that can withstand either downy mildews or powdery mildews, or both classes.

Dan Guravich, Photo Researchers

Downy mildew makes yellow spots on a soybean leaf.

Mildew is a serious problem in damp tropical countries because it attacks clothes unless they are kept dry. Even in temperate regions, clothing should not be allowed to remain wet long.

Mildew may attack bookbindings in damp climates. Books kept in damp or poorly ventilated places also are subject to mildew. To protect books from mildew, keep the volumes in an enclosed, dry bookcase. If books must be stored in an open place, good air circulation will help prevent mildew.

Applying certain chemical solutions to bookbindings may prevent mildew. These solutions, as well as the fungicides used to protect plants from mildews, are highly poisonous and should be used with extreme care. Joe F. Ammirati

Scientific classification. Mildews belong to the division Eumycota in the kingdom Fungi. The powdery mildews are in the family Erysiphaceae. The downy mildews are in the family Peronosporaceae.

Mile is a unit of length. In the inch-pound system of measurement customarily used in the United States, the unit used to measure land distances is the *international statute mile,* or *international land mile.* It is equal to 5,280 feet or 320 rods.

The mile was first used by the Romans. The Roman mile was about 5,000 feet long and had 1,000 paces, each 5 feet in length. The term *mile* comes from *milia passuum,* the Latin words for *a thousand paces.* In the metric system, the unit used to measure land distances is the *kilometer.* One mile equals 1.609 kilometers.

In 1959, the United States adopted the *international foot,* which was slightly smaller than the foot then in use in the United States. The old foot is now known as the *survey foot* and is used only for surveying. The *survey mile,* which equals 5,280 survey feet, is about $\frac{1}{8}$ inch longer than the international statute mile.

Distances on the sea are measured in *nautical, geographical,* or *sea miles.* The *international nautical mile* used primarily in the United States equals exactly 1.852 kilometers, or approximately 1.151 international statute miles. One international nautical mile equals almost exactly 1 minute of the circumference of the earth's surface. The value of 1.852 kilometers per international nautical mile can be derived by dividing the approximate circumference of the earth—40,000 kilometers—by 360 degrees, dividing the result by 60 (the number of minutes in 1 degree), and rounding to three decimal places.

Richard S. Davis

Miles, Nelson Appleton (1839-1925), a noted American military officer, served in the American Civil War, the Indian wars, and the Spanish-American War. He rose to the rank of lieutenant general in the United States Army, the Army's highest rank of his day, without a formal military education. In 1892, he received the Medal of Honor for his service in the Civil War.

Miles was born near Westminster, Massachusetts. He became a volunteer lieutenant when the Civil War started in 1861. He fought in nearly every battle in the East, suffered several wounds, and won rapid promotion. In 1866, he became a colonel in the regular Army.

From 1869 to 1890, Miles led campaigns against the major Indian tribes in the West. The Army's most successful Indian fighter, he defeated the Apache and forced Geronimo, one of their fiercest warriors, to surrender in 1886. In 1894, Miles commanded troops sent

Roman mile **about 5,000 feet**

Kilometer 3,280.840 feet

International nautical mile **6,076.115 feet**

International statute mile **5,280 feet**

Different miles measure distances on land, on sea, and in the air. The Roman mile was about 5,000 feet. The metric system uses kilometers to measure distances. A nautical mile equals about $\frac{1}{60}$ of one degree of the distance around the earth. In the 1500's, people in England measured distances in 660-foot furlongs, so Queen Elizabeth I made the statute mile 8 furlongs, or 5,280 feet.

by President Grover Cleveland to Chicago during the Pullman Strike, a violent labor dispute (see Pullman Strike). He became Commanding General of the Army in 1895. In the Spanish-American War, Miles led the invasion of Puerto Rico in 1898. In 1901, he was promoted to lieutenant general. He retired in 1903. James E. Sefton

Milhaud, *mee YOH,* **Darius,** *da RYOOS* (1892-1974), was a French-born composer noted for his works for the stage. Milhaud wrote 15 operas, 13 ballets, and music for other ballets and for motion pictures. The French poet Paul Claudel wrote the *librettos* (words) for several of Milhaud's works, including his famous opera, *Christophe Colomb* (1928). Milhaud's best-known ballet, *La creation du monde* (*The Creation of the World,* 1923), reflects his interest in jazz.

Milhaud was born Sept. 4, 1892, in Aix-en-Provence in southern France. This region inspired his *Suite Provençale* for orchestra (1936). Milhaud received his music training at the Paris Conservatory from 1910 to 1915. In 1917 and 1918, he served with the French Embassy in Rio de Janeiro, Brazil, and became acquainted with Brazilian popular music. Milhaud used this music in *Saudades do Brasil* (*Memories of Brazil,* 1920-1921), which he composed for piano and later arranged for orchestra.

During the 1920's, Milhaud belonged to a group of young French composers called *Les Six.* He left France in 1940 during World War II (1939-1945). That year, Milhaud joined the faculty of the music department at Mills College in Oakland, California. He retired in 1974.
Richard Jackson

Milhous, *MIHL hows,* **Katherine** (1894-1977), was an American author and illustrator of children's books. She came from a Pennsylvania Dutch background, which influenced her work. Milhous won the 1951 Caldecott Medal for her illustrations for *The Egg Tree* (1950), a picture book she wrote about Pennsylvania Dutch Easter customs. Milhous also wrote and illustrated such picture books as *Lovina: A Story of the Pennsylvania Country* (1940), *Patrick and the Golden Slippers* (1951), *Appolonia's Valentine* (1954), and *Through These Arches: The Story of Independence Hall* (1964). She also illustrated a number of books written by children's authors Alice Dalgliesh and Mabel Leigh Hunt.

Milhous was born Nov. 27, 1894, in Philadelphia. She studied at the Pennsylvania Academy of Fine Arts.

Military aircraft. See Aircraft, Military.

Military discharge ends a person's period of service in the armed forces. Members of the Armed Forces of the United States receive one of five types of discharges: (1) honorable, (2) general, (3) undesirable, (4) bad conduct, and (5) dishonorable.

Honorable discharges are issued to all those whose military behavior has been proper and whose performance of duty has been "proficient and industrious." A person holding such a discharge is entitled to all benefits available to veterans.

General discharges are given to those whose military records do not entitle them to an honorable discharge. A general discharge may be issued if a person has been found guilty by a general court-martial. Veterans with general discharges are eligible for the same benefits as those holding honorable discharges.

Undesirable discharges are given to people considered unfit for military service. They cancel many veteran benefits and prohibit reenlistment in any service.

Bad conduct discharges are given for reasons such as absence without leave, insubordination, and destruction of private property. A bad conduct discharge deprives the holder of all veteran benefits and certain citizenship rights.

Dishonorable discharges may be given for such reasons as theft, desertion, and destruction of government property. They cancel all veteran benefits and some citizenship rights. Ann Alexander Warren

Military insignia. See Insignia; also the pictures in Air Force, U.S.; Army, U.S.; Marine Corps, U.S.; Navy, U.S.

Military Justice, Uniform Code of. See Uniform Code of Military Justice.

Military police are the trained police maintained by a nation's armed forces. On military installations, these men and women have powers similar to those of civilian police. Military police enforce military laws and regulations, control traffic, prevent and investigate crime, apprehend military absentees, maintain custody of military prisoners, and provide physical security for military personnel and property. In combat situations, military police also maintain custody of prisoners of war. When necessary in combat, military police can be ordered to fight as infantry.

In the United States armed forces, police duties are carried out by Military Police (MP) for the Army and Marine Corps, the Shore Patrol for the Navy and Coast Guard, and the Security Police for the Air Force. The functions of the Shore Patrol are more limited than those of other military police. Ann Alexander Warren

Military school is an institution that educates people and trains them in military arts and sciences. All major countries operate military schools. Many United States military schools are privately operated.

Government military schools. In the United States, each branch of the armed forces has its own military schools. Courses in these schools for enlisted men and women range from the repair of guided missiles to food service. The armed forces maintain service academies, officer-candidate schools, and reserve officers training corps for individuals who are learning to become officers. Service academies of the armed forces are the U.S. Air Force Academy at Colorado Springs, Colorado; the U.S. Coast Guard Academy at New London, Connecticut; the U.S. Military Academy at West Point, New York; and the U.S. Naval Academy at Annapolis, Maryland.

Some military schools prepare officers for duties they may have to perform in peace or war. Schools at the first level cover specialized subjects. Schools at the next level stress command and staff work. They include the U.S. Army War College, Naval War College, Air War College, Army Command and General Staff College, College of Naval Command and Staff, Marine Corps Command and Staff College, and Air Command and Staff College. The National Defense University is a joint-service institution and operates at the highest level. It consists of the National War College and the Industrial College of the Armed Forces, both in Washington, D.C., and the Armed Forces Staff College in Norfolk, Virginia.

Other military schools and colleges train students of junior high school, high school, and college age. Students wear distinctive uniforms, and learn the basics of military training, strategy, and tactics. The two state-funded military colleges in the United States are the Citadel in Charleston, South Carolina, and Virginia Military Institute in Lexington, Virginia. These colleges formerly accepted only males but now accept females as well.

In other countries. The United Kingdom trains its officers at the Royal Military Academy located in Sandhurst, the Army Staff College in Camberley, the National Defence College in Latimer, and the Royal College of Defence Studies in London. Canada has the Royal Military College of Canada in Kingston, Ontario; Royal Roads Military College near Victoria, British Columbia; and Collège militaire royal de Saint-Jean in Saint-Jean, Quebec. The chief French military school is Saint-Cyr, in Coëtquidan, Brittany. Russia has the Frunze Academy in Moscow. Ann Alexander Warren

Military science is the study of scientific principles that control the conduct of war. It is also the application of those principles to battle conditions. See also **Air force; Army; Logistics; Navy; War.**

Military service, Compulsory. See **Draft, Military.**

Military training is training in the art and science of war. Modern military training is much more complex than in ancient times. Battles then involved relatively simple formations, weapons, and equipment. Today, troops must know how to use mechanized equipment and intricate scientific instruments. They must be backed up by many more service troops than there are actual fighters. During World War II (1939-1945), nations trained both men and women in a variety of jobs. In some countries, women have also engaged in combat.

All soldiers first learn to obey orders. Combat soldiers learn to handle various weapons: machine guns, bayonets, rifles, pistols, and grenades. They learn how to handle explosives. Soldiers assigned to a specialized branch of the army also get training for a particular job. They may learn to drive a tank, to jump from an airplane, to operate radar, or to build a bridge.

Training schools. In the United States, the Army, Navy, and Air Force maintain a system of schools or training stations for officers and enlisted personnel. Each of these branches also has specialized schools for higher officer training. These schools include the United States Army War College, the Naval War College, and the Air University. The Armed Forces Staff College and the National Defense University are operated jointly by the services. The National Defense University includes the National War College and the Industrial College of the Armed Forces. The National War College teaches military strategy and related subjects in politics, economics, and social problems. The Industrial College of the Armed Forces prepares officers in the military for their duties connected with *procurement* (purchase) and maintenance of supplies and equipment.

Military training for civilians. Many colleges and universities in the United States have Reserve Officers Training Corps units of the Army, Navy, and Air Force, which offer instruction for prospective officers. Students who successfully complete such training may be eligible for commissions in the regular Army, Navy, or Air Force. The Army also conducts a junior branch of its ROTC in some high schools and preparatory schools. The National Guard and Air National Guard are other volunteer organizations offering training to civilians. The individual states and territories conduct these groups.

Compulsory military training. From the days of the ancient Romans, many European countries have tried some form of enforced military service. France introduced a conscription law in 1792. Germany made the greatest progress in developing a military machine under nationwide conscription. It began its program after the Franco-Prussian War (1870-1871).

In the United States, the federal government first tried compulsory military training during the Civil War (1861-1865). Conscription laws providing for military training for male citizens were also in effect during World War I (1914-1918) and World War II. The first U.S. peacetime draft law was enacted in 1940. Ann Alexander Warren

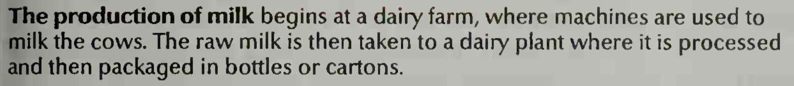
Militia, *muh LIHSH uh,* includes all able-bodied persons who are liable to be called into the armed forces in time of national emergency. The militia of the United States includes the Air Force Reserve, Air National Guard, Army National Guard, Army Reserve, Marine Corps Reserve, and Naval Reserve.

Each of the 13 American Colonies required its citizens to enroll and train in the militia. Militiamen formed almost half of the army that fought in the Revolutionary War in America (1775-1783). The U.S. Constitution gave Congress the right to call up the militia to "execute the laws of the Union." The Militia Act of 1792 placed every "free able-bodied white male citizen" from the age of 18 to 45 in the militia. But it left the control and training of these units to each state. The act of 1903 made all male citizens subject to military service. It placed the militia, by then known as the National Guard, under the control of both state governments and the federal government.



The governments of ancient Egypt, Greece, and Rome all formed militias. Switzerland's militia system was set up in 1291. Militiamen in feudal England had to keep armor and weapons that were inspected twice a year.

Some groups call themselves *militias* even though they are not organized by any government. In Lebanon, for example, private militias did much of the fighting between Christians and Muslims in the mid-1970's and the 1980's. In the United States, right wing groups called militias conduct military exercises, oppose gun control laws, and object to many other forms of government involvement in their lives. Joel D. Meyerson

The production of milk begins at a dairy farm, where machines are used to milk the cows. The raw milk is then taken to a dairy plant where it is processed and then packaged in bottles or cartons.

© Tom Tracy

After milk is packaged, the containers are stored in a large refrigerated room to await delivery to stores and homes.

Milk

Milk is the most nourishing of all foods and a favorite drink of people throughout the world. Milk has almost all the *nutrients* (nourishing substances) that human beings need for growth and good health. In addition, milk has most of these nutrients in large amounts and in such proportions that they can work as a team to help keep the body strong and healthy.

All female mammals produce milk to nourish their young. But when we think of milk, we generally think of the milk that comes from cows. Cows provide most of the milk used in the United States, Canada, and many other countries. In some parts of the world, however, other animals produce the main supply of milk. Goat milk is popular in parts of Europe, Latin America, Africa, and Asia. Camels provide milk in the deserts of Arabia, central Asia, and northern Africa. Some South Americans drink llama milk. In the Arctic, people get milk from reindeer. Sheep provide much of the milk in Greece, Iran, and Turkey. Water buffalo supply milk in Egypt, India, Pakistan, and many countries of Southeast Asia.

Butter, cheese, ice cream, yogurt, and several other foods are made from milk. Milk—or one of its products—is also an ingredient in many foods, such as cakes, casseroles, puddings, and sauces. Milk is also used in making numerous products besides food. For example, manufacturers use *casein,* the main protein in milk, to make waterproof glues, plastics, and paints.

Michael F. Hutjens, the contributor of this article, is an Extension Dairy Specialist in the College of Agriculture at the University of Illinois at Urbana-Champaign.

The United States is the world's leading producer of cow's milk. India and Russia are the other leading milk-producing countries. The United States dairy industry is concentrated in the *Dairy Belt,* which extends from New York to Minnesota. California and Wisconsin lead the states in milk production. Quebec and Ontario are Canada's chief milk-producing provinces.

Food value of milk

This section discusses the nutrients in milk. It also examines the importance of milk in the human diet.

Nutrients in milk. The body needs six kinds of nutrients for energy, growth, and the replacement of worn-out tissue. These nutrients are (1) water, (2) carbohydrates, (3) fats, (4) proteins, (5) minerals, and (6) vitamins.

Interesting facts about milk

Ancestors of today's dairy cows were wild cattle that roamed the forests of northern Europe many thousands of years ago.

Average yearly milk production per cow in the United States totals about 2,000 gallons (7,570 liters), approximately twice as much as in 1960.

Daily food for a dairy cow ranges from 40 to 100 pounds (18 to 45 kilograms) of feed. In addition, a cow requires 10 to 30 gallons (38 to 114 liters) of water a day.

First dairy cattle in what is now the United States were brought from England to the Jamestown colony in Virginia in 1611.

Record milk production by a cow in one year is 7,897 gallons (29,893 liters). This is an average of about 22 gallons (83 liters) per day, enough to provide 88 people with 1 quart (0.95 liter) each. A cow in Marathon, Wisconsin, set the record in 1997.

Milk has been called "the most nearly perfect food" because it is an outstanding source of these nutrients. But milk is not a perfect food because it lacks enough iron and does not provide all vitamins.

Water is the most vital nutrient. The body needs water to carry out all its life processes. Cow's milk is about 88 percent water.

Carbohydrates are a major source of energy for the body. The carbohydrate content of milk is mainly *lactose,* also called *milk sugar.* In addition to providing energy, lactose helps the body absorb the minerals calcium and phosphorus in milk. Our bones and teeth consist largely of these minerals. Lactose also gives milk its sweet taste. See **Carbohydrate.**

Fats, like carbohydrates, provide energy. They also supply certain substances called *essential fatty acids* that the body must have. Fat gives milk its rich flavor. Milk fat also contains vitamins A, D, E, and K, and several other substances. One such substance, *carotene,* gives milk its golden tint. Milk fat appears as tiny *globules.* A drop of milk contains about 100 million such globules. See **Fat.**

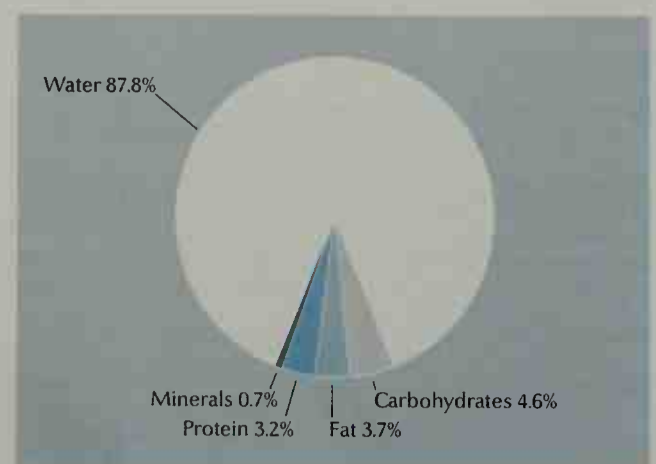
Proteins help the body grow and maintain itself. They also supply energy. The proteins in milk are *complete proteins*—that is, they contain all the *amino acids* (protein parts) needed for building blood and tissue. Only egg proteins and the proteins in some meats have a higher food value than milk proteins have. Casein makes up about four-fifths of the protein content of milk. It is found only in milk. See **Protein.**

Minerals, like proteins, help the body grow and remain healthy. Calcium and phosphorus are the most important minerals in milk. In fact, milk is the chief food source of calcium. Other minerals in milk include potassium, sodium, and sulfur, and smaller amounts of aluminum, copper, iodine, iron, manganese, and zinc.

Vitamins are essential for growth, maintaining body tissue, and the prevention of such diseases as beriberi and rickets. Milk provides more vitamins—and in larger amounts—than do most other natural foods. Milk is an excellent source of vitamins A and B_2 and a good source of vitamin B_1. Other vitamins in milk include vitamins B_6, B_{12}, C, E, and K, and niacin. Milk also has vitamin D, but the quantity is low. Most dairies add extra vitamins A and D to milk. See **Vitamin.**

All milk—human and animal—contains the same nutrients. The amounts differ, however. Compared with cow's milk, for example, the milk from a water buffalo has 3 times as much fat and 1 $\frac{1}{2}$ times as much protein but only about three-fourths the sugar. Human milk has fewer proteins and minerals than cow's milk but about 1 $\frac{1}{2}$ times as much sugar.

In the United States, the federal government requires that whole milk sold as food meet certain standards. Whole milk must contain at least 3.25 percent milk fat and 8.25 percent nonfat milk solids. Some states require a higher percentage of nonfat milk solids in their milk. For example, California requires 8.7 percent nonfat milk solids in its whole milk. Most cow's milk has about 3.7 percent milk fat, 4.6 percent lactose, 3.2 percent protein, and 0.7 percent minerals. The percentages differ somewhat between individual cows and breeds. The quality and composition of milk also depend on what a cow is fed and how the animal is cared for.



Milk in the human diet. Milk is an important part of most people's diet. It is the first food of newborn babies, whether they are breast-fed or bottle-fed. Because of its many nutrients, milk helps the body develop. Children who drink milk grow faster than other children who eat the same foods but drink no milk. Milk can also help people obtain nutrients their diet might otherwise lack.

Doctors and nutrition experts disagree on exactly how much milk a person should drink. In general, they recommend that children and teen-agers drink at least three 8-ounce (240-milliliter) glasses a day. Adults should have at least two glasses daily. Expectant mothers and mothers who are nursing their babies should drink three or four glasses a day.

Many people cannot drink the recommended amount of milk. In most people, for example, levels of *lactase,* the enzyme that breaks down milk sugar, decline with age. As a result, many adults and some children have a condition called *lactose intolerance,* which makes it difficult to digest milk. Lactose intolerance is especially common in Africa, Asia, and South America, and among people of African, Asian, or Native American descent elsewhere. In addition, a small percentage of people are allergic to the protein in milk. Both lactose intolerance and milk-protein allergy produce similar symptoms, including stomach pain and diarrhea.

Finally, many doctors recommend that patients who have a large amount of *cholesterol* in their bloodstream avoid drinking whole milk because of its cholesterol content. Cholesterol is a fatty substance that is found in all animal tissues. However, a high level of cholesterol in the blood may contribute to *arteriosclerosis,* a disease of the arteries that can cause heart attacks. Fat-free milk, also called *skim milk,* contains little cholesterol.

The composition of cow's milk

Milk from farm to table

Millions of people enjoy pure, fresh milk every day, especially at mealtimes. But few realize the many steps required—first at a dairy farm and then at a processing plant—to get this milk to the dining table.

At a dairy farm, cows called *dairy cattle* produce milk under highly sanitary conditions. Most dairy cows in North America are the black-and-white Holstein breed. See **Cattle (Dairy cattle).**

Production. Almost all dairy farmers in industrialized countries use milking machines to milk their cows. Ma-

chines are faster and more sanitary than milking by hand. In some countries, however, milking by hand is still widespread. See Milking machine.

The milk that cows produce is called *raw milk* until it has been pasteurized. Harmful bacteria grow rapidly in raw milk unless the milk is kept clean and cool. Dairy farmers therefore keep their cows and barns clean, and sanitize their milking equipment. Most farmers store raw milk in a refrigerated tank until it can be delivered to a processing plant. As a cow is milked, the milk flows into the tank and is cooled to less than 40 °F (4.4 °C).

Local, regional, and national government agencies set standards of cleanliness for dairy farms and processing plants. To make sure these standards are met, local health inspectors check farms and plants, and test milk in the laboratory. Veterinarians also test cows periodically for two diseases, tuberculosis and brucellosis.

Almost all the fluid milk sold for table use in industrialized countries is classified as *grade A* or *grade 1.* Most communities have special rules regarding the sanitary conditions under which milk must be produced and processed to be classed as grade A or 1. In the United States, the rules are largely based on the Grade A Pasteurized Milk Ordinance, a set of recommendations developed by the Food and Drug Administration (FDA). The states voluntarily adopt this ordinance. Milk moves from state to state with few legal restraints. Representatives from various states work together to resolve problems concerning the sanitary quality of grade A milk.

Many countries or local regions permit the sale of a *manufacturing grade* of milk. It is used chiefly in making such dairy products as butter, cheese, and ice cream.

Marketing. Many dairy farmers are members and joint owners of a dairy *cooperative.* A cooperative picks up the members' raw milk and sells it for them at the highest price to processing plants. Some cooperatives not only pick up the members' milk but also process it.

Many governments set minimum prices that farmers receive for their milk. The U.S. government operates a *price support program.* Under this program, the government buys dairy products when the farm price of milk falls below a minimum. In the European Community, the Common Agricultural Policy guarantees farmers a minimum price for their milk. However, the policy also limits the quantity of milk that they can produce.

Transportation. A dairy cooperative operates large tank trucks to transport the milk of its members. At least every other day, a truck picks up milk from dairy farms in a local region and delivers the milk to a processing plant. The truck's tank is insulated to keep the milk cold, even in hot weather. At each farm, the milk haulers examine and take samples of the milk before pumping it into the tank. The samples are important because all the milk from the various farms becomes mixed in the tank. The samples from each farm go to the local health department and to the milk processor to be tested for composition and quality.

At a processing plant. Much of the milk produced worldwide is processed into various kinds of fluid milk or cream. Most of the rest is made into such dairy products as butter, cheese, and ice cream. A small amount is used to make special types of dairy products, such as *acidophilus milk.* This milk is frequently used for treating intestinal disorders. The following discussion describes

Kinds of milk and milk products

There are many kinds of milk and milk products. They vary widely in flavor, texture, and use. This table briefly describes a few of these foods as defined in the United States and the processes by which they are made.

Milk or milk product	Description	Manufacturing process
*Butter	Churned milk fat.	Pasteurized cream mechanically churned, causing its milk fat to form into butter.
*Cheese	Treated curd of milk.	Bacteria or other agent added to milk to form soft curd; whey, the liquid part of milk, removed from curd; curd then made into different types of cheese.
Cream	Rich milk product containing at least 18 percent milk fat.	Mechanically separated from nonhomogenized whole milk.
Cultured buttermilk	Milk with tangy flavor; may be reduced fat, lowfat, or fat-free.	Acid-producing bacteria added to pasteurized milk; allowed to ferment until desired taste obtained.
Evaporated milk	Whole milk with about 60 percent of its water removed; requires no refrigeration until opened.	Pasteurized whole milk heated in a vacuum to remove proper percentage of water; milk then canned, sealed, and sterilized; or may be sterilized first, then canned and sealed.
Fat-free milk (Skim milk)	Milk that has about 0.1 percent milk fat.	Mechanically separated from nonhomogenized whole milk.
*Ice cream	Sweet, frozen dairy product.	Cream, concentrated milk, sugar, and flavoring mixed together and frozen; air whipped in to give proper texture.
Half-and-half	Milk product containing at least 10.5 percent, but less than 18 percent, milk fat.	Cream mixed with whole milk to obtain proper percentage of milk fat; mixture pasteurized and homogenized.
Lowfat milk	Milk that has about 1 percent milk fat.	Fat-free milk mixed with whole milk to obtain proper percentage of milk fat; mixture pasteurized and homogenized.
Reduced-fat milk	Milk that has about 2 percent milk fat.	Fat-free milk mixed with whole milk to obtain proper percentage of milk fat; mixture pasteurized and homogenized.
Sour cream	Smooth, firm, tangy cream with about 19 percent milk fat.	Acid-producing bacteria added to cream, causing it to sour; cream chilled after proper flavor reached; also made by adding acid and flavoring directly to cream.
*Yogurt	Thick, custardlike form of milk.	Nonfat dry milk mixed with partly skimmed milk; bacteria and flavoring added; mixture ferments, forming tangy curd; curd chilled after desired flavor obtained; fruit and sugar often added.

*Has a separate article in *World Book.*

the processing of fresh fluid milk. To learn how some other dairy products are made, see the table *Kinds of milk and milk products* in this article.

As soon as the tank truck arrives at a processing plant, laboratory technicians check the odor, taste, and appearance of the milk. They also measure the fat content, the number of bacteria, the amount of milk solids, and the residue of *antibiotics* that may have been given to the cattle to treat disease. Technicians further test the milk during and after processing. All this testing helps ensure the quality and purity of the milk. Milk is the most highly tested of all foods.

After the first tests, the milk is pumped into a large refrigerated storage tank. On its way to the tank, the milk passes through a *clarifier.* This machine removes any hair, dust, or similar matter that may be in the milk. After the milk is pumped from the storage tank, it goes through five basic steps. These steps, in order, are (1) separation or standardization, (2) pasteurization, (3) homogenization, (4) fortification, and (5) packaging.

Separation or standardization. Some of the milk that comes from the storage tank is separated. The rest is standardized. In separation, the cream, or fat, is mechanically *skimmed* (separated) from milk. Some of the cream is then either bottled or used to make butter or other dairy products. Some of the remaining skim milk, which is fat-free milk, is also either bottled or used to make such foods as cottage cheese or cultured buttermilk. The rest of the cream and fat-free milk is used to standardize the milk that has not been separated.

In standardization, the fat content of milk is regulated. A device called a *Milko-tester* measures the fat content as the milk flows through a pipeline. If the content becomes lower than the desired level, cream is pumped in with the milk. If the fat content becomes higher, fat-free milk is pumped in. Standardization enables dairies to produce various types of lower-fat milks with a uniform fat content. It also ensures that the fat content of whole milk meets government requirements.

Pasteurization involves heating milk to kill disease-causing bacteria. Nearly all milk sold in industrialized countries is pasteurized. Most is pasteurized by the *high-temperature short-time* (HTST) method, which involves heating milk to 161 °F (72 °C) for 15 seconds and then quickly cooling it. Some milk is pasteurized by the *batch method*—that is, by heating it to 145 °F (63 °C) for 30 minutes. In a method called *ultrapasteurization,* milk is heated to at least 280 °F (138 °C) for 2 or more seconds and then cooled rapidly. Milk treated by any of these methods spoils quickly if not refrigerated. But milk pasteurized by the *ultrahigh-temperature* (UHT) method keeps for months without refrigeration. In this method, milk is heated to about 300 °F (149 °C) for 6 to 9 seconds, then cooled rapidly and stored in sterile containers. UHT-treated milk is also called *sterilized milk.*

Homogenization. Almost all fluid milk sold in industrialized countries is homogenized. Homogenization breaks up the fat globules in milk so the globules do not rise to the top. A machine called a *homogenizer* forces the milk through tiny openings under great pressure. The process increases the number of fat globules and gives every drop of milk the same amount of cream. Milk that has been homogenized tastes richer than nonhomogenized milk.

Fortification improves the food value of milk by adding certain nutrients, especially vitamins and proteins. Some dairies add vitamin D because the quantity is low in milk. They fortify fat-free milk with protein and

How a dairy processes whole milk

After raw milk arrives at a dairy, some of it is separated into fat-free milk and cream. The rest is processed into whole milk. The first step in the process is *standardization.* A Milko-tester indicates whether cream should be added to increase the fat content or fat-free milk to lower it. After the proper fat content is reached, the milk is pasteurized, homogenized, and packaged as whole milk.

Packaging machines automatically fill and seal milk containers with tremendous speed. This dairy worker is adjusting a machine that packages about seventy 1-gallon (3.8-liter) plastic bottles of milk a minute.

vitamin A as well as vitamin D. A few dairies also add other vitamins and some minerals to milk.

Packaging is the final step in the processing of milk. Automatic packaging machines fill and seal milk containers, most of which are bottles or paper cartons. Direct fluorescent light can damage milk that is packaged in certain kinds of plastic containers. It destroys some of the vitamins in milk and can change the milk's flavor. Some plastic containers consist of materials that filter out or reflect fluorescent light.

Refrigerated trucks deliver packaged milk to stores and homes. At one time, home delivery of milk was common. Today, most families buy their milk at a supermarket or other retail store.

History of the milk industry

No one knows when people first used animal milk for food. However, the people of ancient Babylon, Egypt, and India raised dairy cattle as early as 4000 B.C. At that time, the family cow was the chief source of milk. A family used as much milk as it needed and traded or sold the rest to neighbors. This practice is still common in some parts of the world.

In the United States, the family cow was especially common during colonial times. But by 1850, many U.S. farmers had begun to own several dairy cows and to supply milk to people living nearby. With the growth of cities, local laws prohibited keeping cows within city limits. Farmers outside the cities then began to increase the size of their herds and to establish dairy businesses.

As the dairy industry grew, several cities passed laws to control the sale of milk. Some laws made it illegal to add water to milk or to remove cream from it. Boston passed the first such law in 1856. But no early laws set health standards for milk. Many dairies added chemical preservatives to milk. But after some of these chemicals were found to be harmful, laws were passed that prohibited their use. Gradually, cities and states began supervising the industry to protect the public health.

Several inventions and new processes helped speed the growth of the milk industry. In 1856, an American inventor named Gail Borden patented the first successful milk-condensing process. About 1885, dairies began using glass jars and bottles, which workers filled by hand. The invention of a bottling machine in 1886 made filling the containers easier and faster.

In 1890, Stephen M. Babcock, an American agricultural chemist, developed a test to measure the fat content of milk. This test still plays a role in the measurement of fat content. In the 1890's, dairy plants first introduced pasteurization, a process invented by the French scientist Louis Pasteur. Homogenizers gradually came into use after 1900.

In the mid-1980's, researchers and certain dairy farmers in the United States began injecting a *synthetic* (laboratory-produced) substance called *bovine somatotropin* (BST) into test herds to increase the production of milk. This substance, also called *bovine growth hormone,* is almost identical to BST naturally produced by cows. Natural BST stimulates milk production in a cow that has given birth. Synthetic BST supplements the cow's supply of the natural hormone. In 1985, the Food and Drug Administration ruled that milk from the test herds was safe for human consumption. In 1993, the FDA approved the commercial use of synthetic BST. Today, about 30 percent of all milk cows in the United States belong to herds in which BST is used. Other areas of the world in which BST is used include Africa, Latin America, and the Middle East. BST has not been approved for use in Canada or in the countries of the European Union. Michael F. Hutjens

Leading milk-producing states

Amount of milk produced in a year

State	Amount
California	3,748,800,000 gallons (14,620,500,000 liters)
Wisconsin	2,704,500,000 gallons (10,547,700,000 liters)
New York	1,386,000,000 gallons (5,405,600,000 liters)
Pennsylvania	1,297,200,000 gallons (5,059,100,000 liters)
Minnesota	1,103,800,000 gallons (4,305,000,000 liters)

Figures are for 2000.

Questions

What are some common food products made from milk?
What is a dairy *cooperative*? What is its purpose?
What are the three leading milk-producing states?
Why are some people able to digest only a small amount of milk?
What happens to milk during pasteurization? During homogenization?
What is *grade A* milk? *Raw milk*?
What do laboratory technicians at processing plants test in milk?
Why is milk such a nourishing food?
What other animals besides cows supply milk for human use?
How do farmers help prevent the rapid growth of bacteria in raw milk?

Milk snake is a type of kingsnake that farmers once believed took milk from cows. Today, scientists know that no snake is physically able to take milk from a cow. However, any snake might drink milk from a pail because of the milk's water content. There are many subspecies of milk snakes. The best-known subspecies is the *eastern milk snake*. Like other kingsnakes, the milk snake eats lizards and rodents. Milk snakes frequently go into barnyards to hunt for rodents that nest there.

The eastern milk snake may be 4 feet (1.2 meters) long. Some other types of kingsnakes grow to be 6 feet (1.8 meters) in length. Eastern milk snakes are gray with dark-bordered chestnut blotches on the back and sides. Milk snakes found in the western and southern United States have a pattern of rings or blotches of reddish-orange, black, and either white or yellow. Laurie J. Vitt

Scientific classification. The milk snake is a member of the common snake family, Colubridae. It is *Lampropeltis triangulum*.

See also Kingsnake; Snake (picture).

Milking machine is a device that milks cows. Most dairies milk their cows with such machines instead of by hand. The machines cut costs, because they reduce the amount of labor needed to obtain milk. They also help keep the milk clean.

A milking machine consists of a number of tube-shaped cups, a *pulsator*, and hoses. Each cup is composed of a metal shell and a rubber liner. A cow's teats fit into the inner chambers created by the liners. A vacuum in each chamber holds the cup onto the teat. The space between the cup's liner and its shell forms the outer chamber. The pulsator regulates the milking process by changing the pressure in the outer chamber to pull milk from the teat. During the *milking phase*, the pulsator creates a vacuum. During the *rest* or *massage phase*, it produces normal pressure. This alternating pressure, which resembles the sucking of a calf, massages each teat to keep it healthy. After milk is drawn from the teat, the milk flows through the attached hoses and into a pail or pipeline.

Anna Baldwin, a New Jersey farm woman, invented the suction milking machine in 1878. But Carl Gustav de Laval, a Swedish engineer, developed the first commercially successful machine. This device went on the market in 1918. Sidney L. Spahr

Milkweed is the name of more than 100 kinds of plants that have tufts of silky hairs on the seeds and contain a milky juice. The *common milkweed* is one of the best-known milkweeds in North America. It grows along roadsides and in fields and waste places in the eastern United States as far south as Georgia.

The stems of the common milkweed stand from about $3\frac{1}{4}$ to $6\frac{1}{2}$ feet (1 to 2 meters) high and bear large, hairy, pale-green leaves on short stalks. The purplish flowers grow in clusters at the tip of the stem. The flowers bloom from June to August and have a sweet odor that attracts insects. Each flower is shaped so that an insect has to walk through masses of pollen before it reaches the nectar. The insect then flies away with two bundles of pollen on its legs and brings about *cross-pollination* when it visits another milkweed of the same kind (see Pollen [Cross-pollination]).

By autumn, large, rough seed pods develop from the flowers of the milkweed. When the pods ripen and burst open, the wind scatters clouds of seeds. The milkweed can also reproduce itself from its creeping, underground roots. In 1942, milkweed floss was collected as a wartime substitute for the kapok fiber used in life belts. The milky juice of the milkweed contains small amounts of a rubberlike substance. One of the most attractive milkweeds is the *butterfly weed*. Jerry M. Baskin

Scientific classification. The milkweed is a member of the milkweed family, Asclepiadaceae. The scientific name for the common milkweed is *Asclepias syriaca*.

Milky Way is the galaxy that contains the sun, Earth, and other objects in our solar system. It also includes hundreds of billions of stars besides the sun. Huge clouds of gas and dust lie throughout the galaxy, and they constantly form new stars. The Milky Way is so massive that about 10 smaller galaxies orbit it like satellites revolving around a planet.

The name *Milky Way* also refers to the part of the galaxy that can be seen with the unaided eye. On clear, dark nights, this portion of the galaxy appears as a broad, milky-looking band of starlight stretching across the sky. When observed through an entire year, this band appears to circle completely around us in the sky. Dark gaps in the band consist of clouds of gas and dust that block out light from the stars behind them.

Shape of the galaxy. The Milky Way is shaped like a thin disk with a bulge in the center. The bulge consists of a vast, thick bar of stars. The bar stretches for about 15,000 *light-years* across the center of the galaxy. A light-year is the distance that light travels in one year—about 5.88 trillion miles (9.46 trillion kilometers).

Stars, dust, and gas fan out from the central bulge in long, curving arms that form a *spiral* (coiled) pattern. Astronomers believe that the spiral pattern originates at the ends of the bar. Therefore, they classify the Milky Way as a *barred spiral galaxy*. Barred spirals are a common type of galaxy, though not as common as spiral galaxies without bars.

To someone far above the Milky Way, the galaxy would resemble a huge pinwheel. But our view of the Milky Way is dominated by the hazy light from a strip of nearby stars. There are two reasons why we have this view: (1) we are inside the galaxy, and (2) *interstellar dust*

Artwork © Jon Lomberg and the National Air and Space Museum

The Milky Way, our "home" galaxy, is shaped like a thin disk with a bulge in the center. Stars, dust, and gas fan out along the disk in long, curving arms. Viewed from above the edge of the disk, the galaxy resembles a pinwheel, as shown in this artist's rendition. Our sun is roughly half the distance to the edge.

(dust between the stars) partially blocks the starlight.

The flat part of the Milky Way—the disk—contains many young stars and small, irregularly shaped groups of stars called *open clusters* or *galactic clusters.* The disk also has most of the galaxy's gas and dust. A vast number of older stars are in the central bulge.

The bulge and disk are surrounded by a flattened sphere of stars known as the *halo.* The halo contains many of the oldest stars in the galaxy. It also has a few hundred *globular clusters*—dense, spherical systems containing a few hundred thousand old stars.

Size of the galaxy. The diameter of the Milky Way is about 100,000 light-years. The galaxy is about 10,000 light-years thick at the central bulge. Toward the edges of the disk, it is much flatter, with a thickness of only several hundred light-years.

Our solar system is in the outskirts of the galaxy, about 25,000 light-years from the center. The distance between the stars in our section of the Milky Way averages about 5 light-years. Stars in the galactic center are about 100 times closer together.

Astronomers estimate that the total mass of the Milky Way is several hundred billion times that of the sun. The mass contained in stars is concentrated toward the center of the galaxy. Most of the mass of the galaxy, however, is spread out in the halo. This mass is not present in the form of stars, but rather as a poorly understood substance known as *dark matter.* This substance is called dark matter because there is no evidence that it gives off, reflects, or absorbs visible light or any other kind of electromagnetic radiation.

Dark matter interacts with other kinds of matter by means of the gravitational force. It therefore reveals its presence by its gravitational effect on the stars and other objects that we can observe. Because dark matter cannot yet be observed directly, astronomers are not certain about its composition.

The center of the galaxy. All stars and star clusters in the Milky Way orbit the center of the galaxy. The sun completes an almost circular orbit of the center about every 250 million years. Almost all the bright stars in the Milky Way orbit in the same direction. Thus, the entire galactic system appears to rotate about its center.

The galactic center lies in the direction of the constellation Sagittarius. Because the central bulge of the galaxy is in that direction, this is where we can see one of the most prominent sections of the Milky Way— the Great Star Clouds in Sagittarius. These clouds are the portions of the central bulge that are not hidden by dust clouds in the foreground. They appear as continuous clouds because the vast numbers of stars cannot be viewed individually—except with powerful telescopes. Most of these stars are faint, cool, and as old as the galaxy itself.

Clouds of gas and dust prevent astronomers from using visible light to see into the center of the galaxy. However, radio waves, infrared light, and X rays can penetrate the clouds. By observing these kinds of radiation, astronomers have found unusual objects in the central regions.

In the innermost 1,000 light-years of the galaxy are a massive reservoir of gas and dust, strong magnetic fields, and many of the most massive stars in the galaxy. In addition, studies with radio telescopes and infrared

telescopes have shown that a powerful gravitational force comes from the exact center of the galaxy. This force is so strong that the mass responsible for it must be about 3 million times as great as the mass of the sun. Furthermore, this tremendous mass must be packed into a volume of space smaller than our solar system.

The only known kind of object that could be both that massive and that small is a *black hole.* A black hole is an invisible object whose gravitational pull is so great that not even light can escape from it. Astronomers therefore now believe that the center of the Milky Way is occupied by a supermassive black hole.

Another piece of evidence supports the idea of a central black hole: An unusual source of radio and X-ray energy, called Sagittarius A*, is precisely at the center of the galaxy. Gas falling into a supermassive black hole would give off such energy. Mark Morris

Mill, Harriet Taylor (1807-1858), was the wife of the British philosopher John Stuart Mill. She is believed to have contributed important insights for his rethinking of utilitarian doctrine and his belief in increased rights for women and workers.

John Stuart Mill said that Harriet helped him write parts of *On Liberty* (1859), *Principles of Political Economy* (1848), and *The Subjection of Women* (1869). However, many scholars dispute the claim that she cowrote these and others of his books. They attribute only the 1851 essay "Enfranchisement of Women" to her.

Harriet Hardy was born on Oct. 8, 1807, in Walworth, near Durham, England. In 1826, she married John Taylor, a merchant. She met John Stuart Mill about 1830, and the two quickly became close friends. They married in 1851, two years after Taylor's death. Jonathan Riley

See also **Mill, John Stuart.**

Mill, James (1773-1836), a British philosopher and writer, helped develop the *utilitarian* philosophy. Utilitarianism is the belief that the ultimate goal of public policy should be to promote the general happiness. The British philosopher Jeremy Bentham founded utilitarianism. After meeting Bentham about 1808, Mill became his disciple and helped lead a group of utilitarian thinkers who became known as the "philosophical radicals."

Mill's writings clarified key aspects of Bentham's utilitarianism. Mill's best-known book, *The History of British India* (1817), analyzed the history of British colonial policy in India from a utilitarian standpoint. In 1819, largely on the strength of this book, Mill was appointed to the East India Company. Mill's other well-known works include *Analysis of the Phenomena of the Human Mind* (1829), an essay on "Government" (1820), and *Elements of Political Economy* (1821). This last book served as an introduction to the economic theories of his close friend, British economist David Ricardo.

Mill was born on April 6, 1773, in Scotland and graduated from Edinburgh University. He became a Presbyterian minister in 1798, but he left the ministry and moved to London in 1802. Mill's son, John Stuart Mill, became a famous utilitarian philosopher. Jonathan Riley

See also **Bentham, Jeremy; Mill, John Stuart; Utilitarianism.**

Mill, John Stuart (1806-1873), was an important British writer and *utilitarian* philosopher. Utilitarianism is the belief that the ultimate goal of public policy should be to promote the general happiness. Mill modified and expanded upon the principles of earlier utilitarian thinkers, including his father, James Mill, and Jeremy Bentham. He worked closely with his wife, Harriet Taylor Mill.

Mill combined ideas from various schools of thought and transformed utilitarianism into a more liberal philosophy. He argued that adults should be free to think or do anything as long as they do not harm others. He believed in equal rights for men and women. He defended the idea of a free-market economy but believed in reforming private property laws to promote more equal distribution of wealth.

Mill's writings include *A System of Logic* (1843), *Principles of Political Economy* (1848), *On Liberty* (1859), *Considerations on Representative Government* (1861), *Utilitarianism* (1861), and *The Subjection of Women* (1869). His *Autobiography* (1873) was published after his death.

Mill was born on May 20, 1806, in London. He was educated by his father, who taught him such subjects as classical literature, logic, mathematics, and political economy. At 17, he went to work for the East India Company. He served in Parliament from 1865 to 1868.

Millais, *mih LAY,* **Sir John Everett** (1829-1896), an English painter, helped found the Pre-Raphaelite Brotherhood in 1848. The brotherhood was a group of poets and painters who believed that art should present moral messages through uplifting themes. Most of Millais's paintings have literary or religious subjects. He painted detailed and realistic pictures in the Pre-Raphaelite manner until about 1857. *Ophelia,* from this period, is shown in the **Painting** article. He then changed his style, painting sentimental pictures that became extremely popular. He also painted portraits of distinguished Englishmen of his time and illustrated books and periodicals.

Millais was born on June 8, 1829, in Southampton. He was a child prodigy and attended classes at the Royal Academy of Arts when he was only 11 years old.

Millar, Kenneth. See **Macdonald, Ross.**

Millay, *mih LAY,* **Edna St. Vincent** (1892-1950), was an American poet. Many of her poems have romantic themes. She wrote about love and death, about the self and the universe, and about the feelings of rebellious youth. In her treatment of these subjects, she combined sentimentality with wit and sophistication.

Millay was born in Rockland, Maine, and graduated

from Vassar College in 1917. She did some of her best work while very young. "Renascence," a poem about a personal religious experience, was written when she was only 19 years old. *A Few Figs from Thistles* (1920) was one of three works for which she won a Pulitzer Prize in 1923. The other two works were *The Ballad of the Harp-Weaver* and eight sonnets.

Millay's later poetry became increasingly concerned with modern history. *Conversation at Midnight* (1937) deals with events that were leading to World War II. *The Murder of Lidice* (1942) tells about the destruction of a Czechoslovak town by German troops during the war. Millay was fond of the sonnet form, and her many sonnets were published in 1941. A definitive collection of her poems appeared in 1956. She also wrote several plays, including the one-act poetic fantasy *Aria da Capo* (1919). William Harmon

Millennium, *muh LEHN ee uhm,* in science, is any period of 1,000 years. The term is often used to refer to periods before or after the birth of Christ. The year of Christ's birth is traditionally recognized as A.D. 1. The letters *A.D.* are the abbreviation for *anno Domini,* which is Latin for *in the year of our Lord.* Thus, the first millennium since the birth of Christ was the period from A.D. 1 through A.D. 1000. According to this manner of reckoning, the years of the second millennium would be A.D. 1001 through 2000, and the third millennium would begin on Jan. 1, 2001.

Some people mistakenly believe that the third millennium since the birth of Christ begins on Jan. 1, 2000. This error is easy to understand. It seems logical that a millennium would begin when there is a change in the first digit of the number of the year—for example, when the *1* of *1999* changes to the *2* of *2000.* A millennium actually does begin on Jan. 1, 2000—but it is not the third millennium since the birth of Christ. Rather, it is the millennium of all years after Christ's birth having four digits beginning with "2." Because a millennium is any period of 1,000 years, one can reckon a millennium from any starting date. Irene Cockroft

See also **Calendar.**

Millennium, *muh LEHN ee uhm,* means any period of 1,000 years. But in religion, it usually is used to refer to the period mentioned in the New Testament Book of Revelation (20:1-6) as the time when holiness will prevail throughout the world (see **Revelation, Book of**).

Some people have interpreted the passage in Revelation as meaning that Christ will reign on the earth either before or after the 1,000-year period. These views are known as *premillennialism* and *postmillennialism.*

Because the Book of Revelation frequently uses numbers symbolically, other people have interpreted this passage spiritually. They regard the millennium as the long period of time between Christ's first coming and His second coming. Saint Augustine was the first to set forth this view, known as *amillennialism.* It is expressed in his book *The City of God.* Joseph M. Hallman

Millepede. See Millipede.

Miller, Arthur (1915-), is a leading American playwright. His works record the conflict between the individual and the society that establishes the individual's moral code. Miller showed society's morality as valid in *All My Sons* (1947) and *A View from the Bridge* (1955). But in *Death of a Salesman* (1949), *The Crucible* (1953), *Incident at Vichy* (1964), and *The Price* (1968), he showed its morality as false. *Death of a Salesman,* which received a Pulitzer Prize, is generally considered Miller's masterpiece. It tells of Willy Loman, a traveling salesman who chooses popularity and material success as his goals. Destroyed by his choice, Loman commits suicide in the end. The play typifies Miller's belief that the "common man" is the modern tragic hero.

Miller's work generally follows the Ibsen school of realistic drama. But much of the action in *Death of a Salesman* is seen through Loman's mind, thus establishing Miller's debt to expressionistic drama.

Miller was born in New York City. He was married to actress Marilyn Monroe from 1956 to 1961. His autobiographical play *After the Fall* (1964) partly deals with his relationship with Monroe. Miller's other writings include *Focus* (1945), a novel; *The Misfits* (1961), a motion-picture script; and *The Theater Essays of Arthur Miller* (1978). His later plays include *The American Clock* (1980), *The Last Yankee* (1993), and *Broken Glass* (1994). Miller also wrote an autobiography, *Timebends: A Life* (1987).

Mardi Valgemae

Miller, Cincinnatus H. See Miller, Joaquin.

Miller, Dorie (1919-1943), was a famous African American hero of World War II (1939-1945). On Dec. 7, 1941, he was serving as a mess attendant aboard the battleship *West Virginia* at the U.S. naval base on Pearl Harbor in Hawaii. That day, Japan staged a surprise attack on Pearl Harbor, and the *West Virginia* came under fire. Miller had no gunnery training, but he took the place of a dead machine-gun operator and shot down four Japanese aircraft. For this feat, Miller received the Navy Cross, a medal given for great heroism in combat.

UPI/Bettmann

Dorie Miller

Miller was born on a farm near Waco, Texas. His real first name was Doris. He enlisted in the U.S. Navy in 1939. At that time, blacks could serve in the Navy only as cook, steward, mess attendant, or waiter. After the attack on Pearl Harbor, Miller became a steward aboard the aircraft carrier *Liscome Bay.* He was killed when a Japanese submarine torpedo blew up the ship on Nov. 24, 1943.

James L. Stokesbury

Miller, Glenn (1904-1944), was a popular American dance band leader, arranger, and trombonist. Miller's band featured a distinctive sound that he developed by blending a clarinet with four saxophones. The band played smoothly danceable ballads and crisply driving swing numbers. Miller achieved his greatest popularity from 1939 to 1942. During this time he recorded many hits, including "Moonlight Serenade," the band's theme song; "Little Brown Jug"; "In the Mood"; "Tuxedo Junction"; "Pennsylvania 6-5000"; "Chattanooga Choo Choo"; "A String of Pearls"; and "Kalamazoo."

Miller was born in Clarinda, Iowa. From 1926 to 1936, he played trombone in several bands, including those of Tommy and Jimmy Dorsey, Red Nichols, Ray Noble, Ben

Pollack, and Freddy Rich. Miller first formed his own band in 1937.

Miller disbanded his group and joined the United States Army Air Forces in 1942. In the military, he organized and led an acclaimed band made up of American servicemen. While stationed in England, Miller disappeared during an air journey. Nat Hentoff

Miller, Henry (1891-1980), became one of the most controversial American authors of his time. His emphasis on sex and his obscene language led to censorship trials and literary quarrels.

Miller's first important book, *Tropic of Cancer* (1934), was banned from publication in the United States until 1961. It was written in Paris, where Miller had exiled himself from an America he despised. As in all of Miller's work, the plot is not as important as the message. He believed that modern civilization is diseased. People, to be healthy again, must win freedom from society and glorify the self and the senses.

Tropic of Capricorn (1939) is even more poetic and has a stronger sense of prophecy. It mixes moments of mystic joy with descriptions of what Miller saw as the U.S. cultural wasteland. His nonfiction, such as *The Air-Conditioned Nightmare* (1945), reflects the same concerns in its study of modern American culture. But the work includes studies of some Americans whom Miller felt lived successful lives. Miller's basic position never changed, though his later subjects were more literary. He was born in New York City. Victor A. Kramer

Miller, Joaquin, *wah KEEN* (1837-1913), was an American poet who wrote about the West. Today, he is better known for his colorful, adventurous life than for the literary quality of his writing. In his poems, Miller intended to praise Americans and their vast new country. A few of his poems were once popular, notably "Alaska," "Crossing the Plains," and "Columbus." But critics no longer take his verse seriously. They consider his style flat and conventional and his technique severely limited.

Miller was born in Liberty, Indiana. His real name was Cincinnatus Hiner Miller. He took the first name *Joaquin* after writing a poem defending the Mexican bandit Joaquín Murieta. Miller's family moved to Oregon in 1852. According to his own exaggerated account of his life, his "cradle was a covered wagon, pointed west." In Oregon, Miller began a series of exploits that included gold mining and living with the Digger Indians. He also visited England, where his collection *Songs of the Sierras* (1871) was enthusiastically praised. Miller also wrote novels, plays, and the autobiography *Life Among the Modocs* (1873). Elmer W. Borklund

Miller, Samuel Freeman (1816-1890), served as an associate justice of the Supreme Court of the United States from 1862 until his death. He is known for writing the court's decision in the Slaughterhouse Cases.

In the Slaughterhouse Cases, the Supreme Court ruled in 1873 that Louisiana could give one meat company the exclusive right to slaughter livestock in New Orleans. Butchers of other companies were allowed to use the slaughterhouses by paying a fee. Many butchers argued that they were denied their rights under the 14th Amendment of the U.S. Constitution. This amendment forbids the states to deny citizens any rights granted by federal law. Miller's interpretation of the law upheld the power of the states to regulate most business without federal interference. The court's decision had the effect of limiting the federal government's power to protect the rights of blacks, most of whom had recently been freed from slavery.

Miller was born in Richmond, Kentucky. He received an M.D. degree from Transylvania University and practiced medicine for several years. He later instructed himself in the law. In 1850, Miller moved to Iowa, where he became a leading attorney. C. Peter Magrath

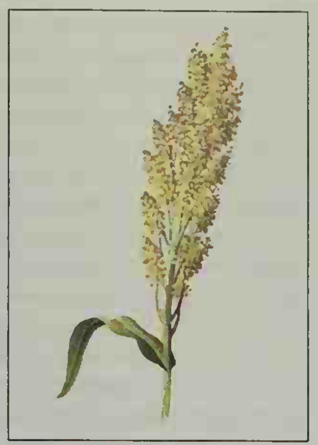
Miller, William Edward (1914-1983), was the Republican nominee for vice president of the United States in the 1964 election. Senator Barry M. Goldwater and Miller were defeated by a Democratic ticket headed by President Lyndon B. Johnson and Hubert H. Humphrey.

Miller, a New Yorker, served in the U.S. House of Representatives from 1951 to 1965 and was Republican national chairman from 1961 to 1964. He gained a reputation as a tough debater and campaigner, and a good organizer. Miller headed his party's congressional campaign committee in 1960. The Republicans gained 22 seats in the House, even though their presidential candidate, Richard M. Nixon, was defeated. Republican leaders gave Miller much credit for the victories. Miller also became known for his barbed comments about Democrats. Goldwater indicated this was one reason he chose Miller as his running mate.

Miller was born in Lockport, New York. He attended the University of Notre Dame and Albany Law School. He served in the Army during World War II (1939-1945), and later helped prosecute German war criminals at the Nuremberg trials. Miller entered politics when Governor Thomas E. Dewey of New York appointed him district attorney of Niagara County in 1948.

Stephen E. Ambrose

Milles, *MIHL luhs,* **Carl** (1875-1955), was a Swedish-American sculptor. He became famous for creating fountains that combine graceful figures with splashing water. Milles studied the art of the past and attempted to create a contemporary classical style. His elongated figures emphasize action and gesture and often have symbolic significance. Milles's works include *Meeting of the Waters* (1940), in St. Louis, Missouri, and *Fountain of Faith* (1952), in Falls Church, Virginia.



Milles was born in Lagga, Sweden, near Uppsala. He came to the United States in 1929 and became a citizen in 1945. He taught for many years at the Cranbrook Academy of Art in Bloomfield Hills, Michigan, which has a collection of his works. Milles's home in Lidingö, near Stockholm, has been made into a park and museum called the Millesgården. Joseph F. Lamb

Millet, *MIHL iht,* is any one of a group of grasses that produce small, edible seeds. The seeds are an important source of food in the dry regions of Asia and Africa. People grind the seeds into flour for flat breads and thin, fried cakes, or they use the seeds in making porridges. In the United States, millet seeds, leaves, and stems serve as feed for livestock.

During ancient and medieval times, millet was the chief crop of Europe and parts of Asia and Africa. However, it was unsuited for making yeast-raised breads and eventually lost popularity to wheat and other grains. Today, India, China, and Nigeria lead the world in producing millet.

There are about 10 species of millet. Most varieties

grow 1 to 4 feet (0.3 to 1.2 meters) tall. The seeds develop in a cluster called a *seed head* at the top of the stem. Millet matures rapidly and is sometimes planted as an emergency crop after a previous crop has failed. Many varieties can grow in hotter, drier weather and in less fertile soils than most other grains can. The chief species of millet include (1) *pearl millet,* (2) *foxtail millet,* and (3) *proso millet.*

WORLD BOOK illustration by Robert Hynes
Millet

Pearl millet, also called *cattail millet* or *candle millet,* serves as a major food for many people in India and Africa. Farmers in the southeastern United States grow pearl millet mainly for grazing livestock. More pearl millet is produced in the United States than any other variety. Pearl millet grows up to 15 feet (4.6 meters) tall. Its seed head looks like a long, narrow spike.

Foxtail millet, also called *Italian millet* or *hay millet,* is grown as a food crop in China, Kazakhstan, Russia, and Ukraine. In the United States, farmers in the Great Plains cultivate foxtail millet primarily for hay but also for grain and birdseed. It ranks second to pearl millet in order of production. Foxtail millet normally is 2 $\frac{1}{2}$ to 5 feet (0.8 to 1.5 meters) tall.

Proso millet, also called *hog millet* or *Hershey millet,* forms a major part of the diets of many Asians. The hulled seeds are eaten as cooked cereal, and flour from the seeds is often substituted for rice flour. In the United States, proso is used for livestock feed and for birdseed. Its food value for livestock is almost as great as that of corn. But proso seeds are extremely hard and must be finely ground before being fed to livestock. Proso usually grows from 1 to 2 feet (0.3 to 0.6 meter) tall. It has coarse, hairy stems that make poor hay. Donald J. Reid

Scientific classification. Millet belongs to the grass family, Poaceae or Gramineae. The scientific name for pearl millet is *Pennisetum glaucum.* Foxtail millet is *Setaria italica,* and proso millet is *Panicum miliaceum.*

Millet, *mee LEH,* **Jean François,** *zhan frahn SWAH* (1814-1875), a French artist, was the most significant painter of peasant life of the 1800's. In 1849, he settled in the village of Barbizon near the forest of Fontainebleau. He spent almost all the rest of his life there painting scenes from rural life. His most popular works include *The Sower* (1850), *The Gleaners* (1857), and *The Angelus* (1859). Such works dignify their subjects, portraying rural life at a time when universal suffrage in France made the peasant an important political force.

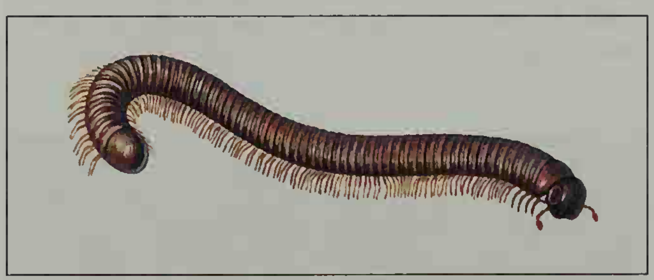
Millet was born in Gruchy, near Cherbourg. He was descended from well-to-do farmers in Normandy, and his knowledge of peasant life came from the perspective of a prosperous farmer. Millet's paintings became especially popular with American and French industrialists of the late 1800's. These industrialists appreciated the idea of hard work and social order, which Millet's paintings seemed to endorse. Millet influenced a number of artists, including the famous painters Vincent van Gogh and Georges Seurat. Richard Shiff

See also Barbizon School.

Milligan, Ex parte. See Ex parte Milligan.

Millikan, *MIHL uh kuhn,* **Robert Andrews** (1868-1953) was a distinguished American physicist. He is noted for his measurement of the electrical charge carried by the electron and for his experiments with cosmic rays. Millikan won the Nobel Prize for physics in 1923.

Millikan's Nobel Prize work included a series of experiments, begun in 1909, to study the charge carried by an electron. He sprayed drops of oil into a special chamber and measured how the charges carried by electrons in the drops affected the drops' fall. Millikan's prizewinning work also included another group of experiments that helped prove Albert Einstein's mathematical explanation of the photoelectric effect (see Einstein, Albert).



From the 1920's through the 1940's, Millikan compared the intensity of cosmic rays at various latitudes and altitudes. The data Millikan collected helped scientists study how the earth's magnetic field deflects cosmic rays as they arrive from outer space.

Millikan was born in Morrison, Illinois. He received a Ph.D. degree from Columbia University in 1895. He taught at the University of Chicago from 1896 to 1921. From 1921 to 1945, he served as the head of the California Institute of Technology. Daniel J. Kevles

See also Cosmic rays; Electron; Muon.

Millipede, *MIHL uh peed,* also spelled *millepede,* is a wormlike, many-legged animal. Millipedes have segmented bodies. Two pairs of legs attach to most of their body segments. The word *millipede* means *thousand-footed,* but no millipede has as many as 1,000 feet. Some *species* (kinds) have up to 115 pairs of legs.

Millipedes range from less than $\frac{1}{8}$ inch (3 millimeters) to up to 9 inches (23 centimeters) long. The animals have round heads that bear a pair of short antennae. Millipedes usually feed on decaying plant life, but some species also attack crops growing in damp soil. They live in dark, damp places, under stones and rotting logs. When they are disturbed, millipedes usually coil up. Many types of millipedes give off foul odors. A few species are capable of producing fluids containing cyanide poison. About 7,500 species of millipedes are found throughout the world. Edwin W. Minch

WORLD BOOK illustration by James Teason
The millipede is a wormlike, many-legged animal. Some species have up to 115 pairs of legs.

Scientific classification. Millipedes are classified in the phylum Arthropoda. They make up the class Diplopoda.

Mills, Robert (1781-1855), was one of the first Americans trained as an architect and engineer. He designed the Washington Monument in Washington, D.C., which for many years was the tallest structure in the world (see

Washington Monument). Mills designed more than 50 important buildings. They include the United States Post Office, Treasury, and Patent Office buildings in Washington, D.C. His nongovernment buildings include churches and homes. Mills was born in Charleston, South Carolina. Leland M. Roth

Milne, *mihln,* **A. A.** (1882-1956), an English author, became famous for his children's stories and poems. Two of Milne's books, *Winnie-the-Pooh* (1926) and *The House at Pooh Corner* (1928), have become masterpieces of children's literature.

Milne based the characters in the Pooh stories on his son, Christopher Robin, and the young boy's stuffed animals. The stories describe the adventures of Christopher Robin and his animal friends in a forest called the Hundred Acre Wood. Some of the characters in the stories include Winnie-the-Pooh, a bear; Piglet, a small pig; and Eeyore, an old donkey (see **Literature for children** [picture: Winnie-the-Pooh]). In his autobiography, *It's Too Late Now* (1939), Milne told how the stuffed animals led to the creation of the characters in the Pooh stories.

In addition to the Pooh stories, Milne wrote two classic collections of children's poems, *When We Were Very Young* (1924) and *Now We Are Six* (1927). Milne also created novels, short stories, and plays for adults. He wrote a famous detective novel, *The Red House Mystery* (1922). His comic plays include *Mr. Pim Passes By* (1919) and *The Truth About Blayds* (1921). He also wrote his *Autobiography* (1939).

Alan Alexander Milne was born in London, on Jan. 18, 1882, and graduated from Cambridge University in 1903. From 1906 to 1914, he served as assistant editor of *Punch,* a humor magazine. Carol Tecla Christ

Milne, *mihln,* **David Brown** (1882-1953), was an important Canadian painter. Milne is best known for creating simplified arrangements of flattened forms with short, broken brushstrokes. Milne primarily painted landscapes and still lifes, using either oil paint or water colors. He also made many color prints using a method called *drypoint etching.* Milne was born near Paisley, Ontario, on Jan. 8, 1882. In 1904, he moved to New York City to study art. Several of his works were displayed there in the Armory Show of 1913, a famous exhibit of American and European modern art. Milne lived and painted mostly in rural New York from 1919 to 1928, when he returned to Canada. Jeremy Adamson

Ollie Matson's House Is Just a Square Red Cloud (1931), an oil painting on canvas; National Gallery of Canada, Ottawa, the Vincent Massey Bequest, 1968

A landscape by David Milne portrays a rural scene in southern Ontario. The painting is typical of the artist's abstract style and his use of short, broken brushstrokes.

Milnes, *mihlnz,* **Sherrill** (1935-), is an American operatic baritone known for his rich voice and great range. He specializes in Italian operas, particularly those by Giuseppe Verdi. He was born in Hinsdale, Illinois, on Jan. 10, 1935, and studied voice at Drake University. He first sang a major role in 1960 with Boris Goldovsky's New England Opera Company and toured with the company from 1960 to 1965. Milnes has appeared regularly at the Metropolitan Opera in New York City since his debut in 1965 as Valentin in Charles Gounod's *Faust.* He has also sung with other companies. Milnes wrote an autobiography, *American Aria* (1998). John H. Baron

Milos, *MEE laws,* or Melos, is a Greek island in the Aegean Sea (see **Greece** [map]). A remarkable statue of the goddess Venus was found on Milos in 1820. This statue is called the Aphrodite of Milos, or the Venus de Milo (see **Venus de Milo**). The island covers about 58 square miles (151 square kilometers) and has about 5,000 people. Its economic activities include tourism and the production of olives and tobacco. John J. Baxevanis

Milošević, *mee LOH shehv ihtch,* **Slobodan,** *SLAW baw duhn* (1941-), was president of Yugoslavia from 1997 to 2000. From 1989 to 1997, he had served as president of Serbia, one of the republics of Yugoslavia.

Milošević became known for his extreme nationalism. In 1989 and 1990, he abolished the power of self-government held by the Serbian provinces of Kosovo and Vojvodina. He supplied arms and troops to Serbs living and fighting in Croatia and Bosnia-Herzegovina, two former republics of Yugoslavia that declared independence in the early 1990's. Milošević urged Serbs to practice the policy of *ethnic cleansing*—to rid Serbian-held areas of all non-Serbs. In early 1998, he sent Serbian police to attack villages in Kosovo, where most of the people are ethnic Albanians. The crisis rapidly escalated, and forces of the North Atlantic Treaty Organization intervened. See **Kosovo; Serbia; Yugoslavia.**

In 1999, the International Criminal Tribunal for the former Yugoslavia *indicted* (formally accused) Milošević on charges of crimes against humanity and of violating the laws and customs of war. The indictment marked the first time that a sitting head of state had been charged with war crimes.

In the presidential election of 2000, opposition candidate Vojislav Kostunica won the majority of votes. Milošević called for a runoff election, but the opposition claimed victory. Protesters flooded the streets of Serbia's major cities to support Kostunica. Milošević conceded defeat, and Kostunica formed a new government.

In 2001, Milosevic was arrested by the Yugoslav government on a variety of corruption charges. After much debate within Yugoslavia and under pressure from other countries, Milosevic was delivered to the International Criminal Tribunal for the former Yugoslavia. His trial on war crimes charges began in 2002.

Milošević was born on Aug. 29, 1941, in Požarevac, Serbia. He graduated from the University of Belgrade and became active in the Yugoslav Communist Party. In

1986, he became head of the Central Committee of the League of Communists of Serbia. Sabrina P. Ramet

Milstein, *MIHL styn,* **Nathan** (1904-1992), was a well-known and beloved violinist. He became known particularly for his interpretations of Bach violin sonatas and the great violin concertos. Milstein was born on Dec. 31, 1904, in Odessa, Ukraine (then part of the Russian empire). Early in his life, he played concerts with the famous pianist Vladimir Horowitz in Russia. Milstein came to the United States in 1929 to make his American debut with the Philadelphia Orchestra. Stephen Clapp

Miltiades, *mihl TY uh DEEZ* (540?-488? B.C.), was a famous general of ancient Athens. He defeated the Persians at the Battle of Marathon in 490 B.C., during the wars between Greece and Persia (see Marathon).

Miltiades belonged to an aristocratic Athenian family. About 516 B.C., while securing trade routes for Athens, he made himself ruler of what is now the Gallipoli Peninsula in Turkey. He probably fought against Persian forces led by Darius. He lost his throne about 492 B.C. and was forced to flee to Athens. Persians invaded Greece in 490 B.C., and the Athenians made Miltiades a general. Experienced at fighting the Persians, he persuaded the other generals to attack the enemy at Marathon. After defeating the Persians and driving them from Greece, he commanded a fleet in the Aegean Sea. Jack Martin Balcer

Milton, John (1608-1674), was an English poet and political writer. He is the author of *Paradise Lost* (1667, revised 1674), considered by many to be the greatest epic poem in the English language. He also wrote *Paradise Regained* (1671) and *Samson Agonistes* (1671). Milton composed the first two of these works, and probably also the last, when he was totally blind.

Milton wrote *Paradise Lost* to "justify the ways of God to man." The 12-book poem retells the Biblical story of the Creation and the fall of Adam and Eve against the backdrop of Satan's rebellion against God and expulsion from heaven (see Doré, Gustave [picture]). *Paradise Regained* is a four-book "brief epic" written, like *Paradise Lost,* in blank verse. Based loosely on the Gospels, it narrates Christ's successful withstanding of Satan's temptations. *Samson Agonistes* tells the Biblical story of Samson in the style of Greek tragic drama. It depicts Samson, betrayed by Dalila (Delilah) and blinded by the Philistines, defeating his captors at the cost of his life.

Milton had a thorough knowledge of classical Greek and Latin authors and was greatly influenced by them. But, as a Protestant, he emphasized the Bible as interpreted by the individual believer. Through his poetry, Milton wanted to do for England "what the greatest and choicest wits of Athens, Rome, or modern Italy, and those Hebrews of old" did for their countries "with this over and above of being a Christian."

His early life and works. Milton was born in London on Dec. 9, 1608. He attended St. Paul's School and then Christ's College at Cambridge University. While at Cambridge, he wrote "On the Morning of Christ's Nativity" (1629) and the companion poems "L'Allegro" and "Il Penseroso" (both 1631?). Although his early training prepared him for a religious career, he came to believe "tyranny had invaded the church." He chose instead to dedicate himself to God's service as a poet. Upon graduating from Cambridge in 1632, he went to Horton, his father's country home, to study and write.

At Horton, Milton wrote two major pieces. *Comus* (1634), a *masque* (dramatic presentation with music), concerns the nature of virtue. Milton wrote the words, and the noted musician Henry Lawes wrote the music. "Lycidas" (1637), considered by many to be the finest short poem in English, is a pastoral elegy commemorating the death of his friend Edward King. In this poem, Milton for the first time subordinated classical sources to a Christian vision as he did in his mature art.

Milton left Horton in 1638 for a 15-month European tour. While in Italy, Milton heard of a growing conflict between the bishops of the Church of England and the Puritans. He returned to England to support the Puritan cause through a series of political writings.

Middle years. Civil discord divided England from 1640 to 1660. King Charles I and the bishops of the Church of England clashed with the Puritans over policies of church and state, and civil war broke out in 1642. The Puritans defeated the King's forces, and Charles was beheaded in 1649. Parliament then established a Commonwealth government led by Oliver Cromwell. See England (The Civil War). During this 20-year period, Milton left poetry to work on behalf of Parliament and the Commonwealth through his prose. In his writings, he championed radical political and religious views. In *Of Reformation in England* (1641), Milton criticized the Church of England. In *The Ready and Easy Way to Establish a Free Commonwealth* (1660), he attacked the prospect of the restoration of King Charles II to the throne. He defended the people's right to choose and depose their rulers in *The Tenure of Kings and Magistrates* (1649).

Milton married 16-year-old Mary Powell in 1643. But their marriage was unhappy. She left Milton after a month or two and did not return for two years. Milton gained notoriety by writing a series of pamphlets in favor of divorce in certain cases. In 1644, he published his most famous prose work, *Areopagitica,* a defense of freedom of the press.

Milton's work and constant study strained his weak eyes, and he was completely blind by 1652. His wife died the same year. He wrote the sonnet "When I Consider How My Light Is Spent" (1655) about his blindness. In 1656, Milton married Katherine Woodcock. She died 16 months later. Milton probably wrote the sonnet "Methought I Saw My Late Espoused Saint" (1658) about her.

Retirement. Charles II was restored to the throne in 1660. Several people held responsible for the execution of Charles I were executed. Milton was arrested, but not harmed. He retired and married Elizabeth Minshull in 1663. Milton wrote *Paradise Lost, Paradise Regained,* and probably *Samson Agonistes,* his masterpieces, during his final years. These works are in part a response to his own blindness and the collapse of the Puritans' hopes for the establishment of Christ's kingdom on earth. Milton's major poems fulfill his ambition to "leave something so written to aftertimes, as they should not willingly let it die." They confirm his reputation as England's foremost nondramatic poet. Peter L. Rudnytsky

Milwaukee lies in southeastern Wisconsin, along Lake Michigan. It is the state's largest city and an important industrial center and port. The downtown area shown here overlooks the Milwaukee River, one of three rivers that flow through the city.

Milwaukee, *mihl WAW kee,* is the largest city in Wisconsin and one of the major industrial centers of the United States. The city ranks as one of the country's leading manufacturers of automobile parts, beer, and electrical and nonelectrical machinery.

Milwaukee lies on the western shore of Lake Michigan, about 90 miles (140 kilometers) north of Chicago. The city's excellent harbor has made Milwaukee an important Great Lakes port.

Milwaukee's name comes from the Milwaukee River. Most historians say that the river's Algonquian Indian name, *Millioke,* means *good land.* Others translate the name as *great council place.* Milwaukee is often called the *Cream City* because of its many old cream-colored brick buildings.

Descendants of German immigrants make up a large part of Milwaukee's population. Business and street names, cultural events, and famous restaurants in Milwaukee are reminders of the city's German heritage.

Solomon Juneau, a French-Canadian fur trader, settled in the Milwaukee area in 1818. He established a town on the east side of the Milwaukee River in 1833. The town later combined with neighboring villages and became Milwaukee.

Trade accounted for much of the city's early growth. During the 1860's, Milwaukee was one of the leading grain markets in the United States. However, by the late 1800's, manufacturing had replaced trade as the city's chief source of income.

The Socialist Party played an important role in local politics during the 1900's. In 1910, Milwaukee became the first major city in the United States to elect a Socialist mayor.

Metropolitan Milwaukee

Milwaukee, the seat of Milwaukee County, covers 106 square miles (275 square kilometers), or about 45 per cent of the county. It extends about 10 miles (16 kilometers) along the shore of Lake Michigan. The city's metropolitan area occupies 1,497 square miles (3,877 square kilometers) and covers four counties—Milwaukee, Ozaukee, Washington, and Waukesha. About 28 percent of the state's people live in this metropolitan area.

The city. Milwaukee lies on a bluff overlooking a crescent-shaped bay. Three rivers—the Kinnickinnic, the Menomonee, and the Milwaukee—flow through the city to the bay.

The streets of Milwaukee run in a checkerboard pat-

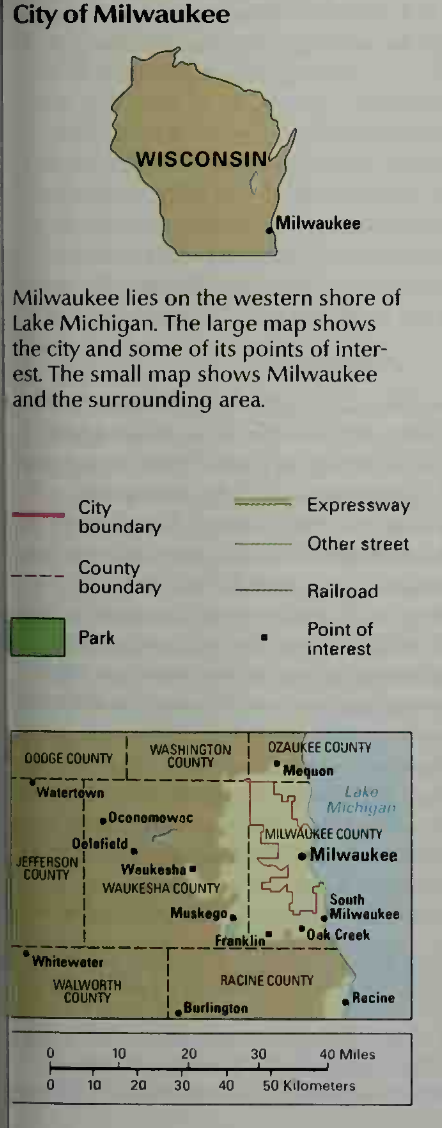
Facts in brief

Population: *City*—596,974. *Metropolitan area*—1,500,741. *Consolidated metropolitan area*—1,689,572.
Area: *City*—106 mi² (275 km²). *Metropolitan area*—1,497 mi² (3,877 km²). *Consolidated metropolitan area*—1,838 mi² (4,760 km²).
Climate: *Average temperature*—January, 22 °F (−6 °C); July, 71 °F (22 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—30 inches (76 centimeters). For the monthly weather in Milwaukee, see **Wisconsin** (Climate).
Government: Mayor-council (four-year terms).
Founded: 1830's. Incorporated as a city, 1846.

tern. Many north-south streets have numbers instead of names. The Menomonee Valley, where many manufacturing companies are located, divides the city into the North Side and South Side. The main business district lies north of the valley, and older residential areas and industrial districts are to the south.

Downtown Milwaukee extends west for about 2 miles (3 kilometers) from the lakefront. Banks, department stores, office buildings, restaurants, and specialty shops line Wisconsin Avenue, the city's main street. Government buildings include City Hall on East Wells Street and the County Court House on North 9th Street. At the downtown's west end stand the Bradley Center and the Milwaukee Exposition Convention Center and Arena (MECCA). The Bradley Center hosts sports and other entertainment events. The MECCA consists of the Arena, which hosts chiefly trade shows and conventions; the Auditorium, where exhibitions and stage shows are held; and the Convention Center.

The metropolitan area. A network of freeways connects downtown Milwaukee and its suburbs. West Allis and Wauwatosa, the largest suburbs, lie west of the city. Other suburbs include Cudahy, Oak Creek, Shorewood, and Whitefish Bay. Large shopping centers, such as Bay Shore, Brookfield Square, and Southridge, serve the suburbs. The metropolitan areas of Milwaukee-Waukesha and of Racine, Wisconsin, form the Milwaukee-Racine Consolidated Metropolitan Statistical Area.



Symbols of Milwaukee. The city flag, adopted in 1954, has a large gear to represent manufacturing. It also has symbols for Milwaukee's government, history, and shipping industry. Scenes on the city seal stand for education and transportation.

The people

African Americans make up about 37 percent of the city's population. Many blacks live in the inner city, close to the downtown area. Hispanic Americans account for 12 percent of the city's people. About 17 percent of the people have German ancestry. Other groups include people of English, Irish, Italian, Mexican, or Polish de-

WORLD BOOK maps

City of Milwaukee

Milwaukee lies on the western shore of Lake Michigan. The large map shows the city and some of its points of interest. The small map shows Milwaukee and the surrounding area.

J. Blank, FPG

The Mitchell Park Conservatory, famous for its huge glass domes, features rare plants and flowers in natural settings.

scent. Nearly 11 percent of Milwaukee's residents speak a language other than English at home.

Milwaukee has had some serious racial disturbances. In 1967, riots broke out in the black community. Civil rights groups have organized marches, picketings, and sit-ins to protest discrimination. Various groups work to aid minorities and improve race relations. Poverty is also a major problem in Milwaukee, where 1 out of 5 people lives below the poverty line.

Economy

Industry. The Milwaukee area has about 3,000 manufacturing plants that employ about 23 percent of the area's work force. The chief products include automobile parts, beer, electrical equipment, and farm and factory machinery. Other industries produce construction and mining equipment, food products, iron and steel forgings, and leather goods.

Finance and trade. The Northwestern Mutual Life Insurance Company, one of the nation's largest insurance firms, is in Milwaukee. Several other major insurance companies and banks are also headquartered there.

The wholesale trade of beer, dairy products, and machinery is important to the city's economy. About 51 percent of Milwaukee's workers hold jobs in service industries, including about 23 percent in wholesale and retail trade.

Transportation. Milwaukee's harbor handles about $2\frac{1}{4}$ million tons (2 million metric tons) of cargo annually. Ships connect the city with about 100 overseas ports by way of the St. Lawrence Seaway.

Passenger trains and five rail freight lines serve Milwaukee. The Milwaukee area has an extensive system of expressways. Milwaukee's main airport is Mitchell Field.

Communication. About 30 radio stations, 6 television stations, including 2 educational stations, and 1 cable TV system serve the Milwaukee area. Journal Communications, Inc., owns the city's only daily newspaper, the *Milwaukee Journal Sentinel.*

Education

The Milwaukee public school system includes about 140 elementary and secondary schools, with an enrollment of about 90,000 students. More than 29,000 students attend about 125 parochial and other private schools in the city.

The University of Wisconsin-Milwaukee, the city's largest university, has about 25,500 students. It includes several skyscrapers and dominates the northeast side of the city. About 12,000 students attend Marquette University. Alverno College, Cardinal Stritch University, Concordia University, Mount Mary College, and Wisconsin Lutheran College are also in the area. Training for the Roman Catholic priesthood is provided at the graduate level by St. Francis Seminary, which is located in nearby St. Francis.

Other institutions of higher learning in the Milwaukee area include the Medical College of Wisconsin, Milwaukee Institute of Art and Design, and the Milwaukee School of Engineering. The Milwaukee Area Technical College is one of the nation's largest vocational and adult education centers.

The Milwaukee public library system has over 2 million books. It includes 13 branches.

Cultural life

The arts. The city's Performing Arts Center houses the Milwaukee Symphony Orchestra, the Milwaukee Repertory Theater, a choral group, a ballet, and an opera company. The Pabst and Riverside theaters provide elegant settings for stage performances. Blues and rock musicians and other entertainers perform at Milwaukee's many nightclubs.

Museums. The Milwaukee Art Center, in the city's lakefront War Memorial Center, displays American and European paintings and sculpture. The Milwaukee Public Museum contains many natural-history exhibits. It also has a model of a Milwaukee street as it looked in the early 1900's. The Milwaukee County Historical Center features exhibits of local history.

Recreation

Parks. The Milwaukee County Park System includes 140 parks and parkways and covers more than 14,000 acres (5,700 hectares). The largest park in the county system, Whitnall Park, occupies about 1,200 acres (486 hectares). The park features the beautiful Alfred Boerner Botanical Gardens, which have more than 1,000 species of flowers. A conservatory in Mitchell Park displays plants of desert, temperate, and tropical climates in their natural settings. The Milwaukee County Zoo has wide moats and glass-enclosed cages, rather than bars. Visitors may tour the zoo in a miniature train or in a rubber-tired "zoomobile."

Sports. Milwaukee has two professional sports teams, the Milwaukee Brewers of baseball's National League and the Milwaukee Bucks of the National Basketball Association.The nation's top golfers compete in the Greater Milwaukee Open, held every September.

Annual events and places of interest in the Milwaukee area include:

Lakefront Festival of Arts, in late spring. Viewers can see thousands of paintings on the lawns surrounding the Milwaukee War Memorial Center.

Summerfest, an 11-day celebration in late June and early July, features fireworks displays, a Fourth of July parade, and music and stage entertainment by various ethnic groups. Ethnic festivals

are held on the lakefront every weekend from Summerfest until Labor Day.
Greek Orthodox Church of the Annunciation in nearby Wauwatosa. Designed by the famous American architect Frank Lloyd Wright, it features an unusual style of architecture.
Joan of Arc Chapel on the Marquette University campus. This chapel, built in France during the 1400's, was reconstructed on the campus in the 1960's.
Kilbourntown House in Estabrook Park was the home of Benjamin Church, a pioneer architect. Church built it in 1844.
State Fair Park, in suburban West Allis, has facilities for rides, stage entertainment, and automobile races. About 1 million people visit the park during the annual 11-day Wisconsin State Fair in August.
Great Circus Parade, held in July through downtown streets, is the largest parade of its kind in the world. It features classic circus wagons pulled by teams of horses.

Government

Milwaukee has a mayor-council form of government. The voters elect the mayor to a four-year term. The mayor appoints major department heads and members of various boards and commissions. Most of the appointments are subject to approval by the council. The mayor has veto power over some council decisions and may also propose legislation. Milwaukee is divided into 17 districts called *wards.* The voters of each ward elect one representative, called an *alderman,* to the city council, officially called the Common Council. The aldermen serve four-year terms. Property taxes provide nearly half the city's revenue. Other sources of revenue include state and federal aid.

The Milwaukee city government faces many problems, including decreasing revenue and air and water pollution. In an effort to solve these problems, Milwaukee leaders work chiefly with two groups. These groups are the Greater Milwaukee Committee, a voluntary organization of civic leaders, and the Southeastern Wisconsin Regional Planning Commission, which is both state and federally supported.

History

Early development. The Fox, Mascouten, and Potawatomi Indians hunted in the Milwaukee area before the first white settlers came. In 1674, Father Jacques Marquette, a French missionary, stopped at the site. Later, other missionaries and fur traders began to visit the area. One trader, Jacques Vieau, opened a trading post there in 1795. Solomon Juneau, Vieau's clerk and son-in-law, settled in the area in 1818. In 1833, Juneau founded a town on the east side of the Milwaukee River.

During the 1830's, many settlers came from the Eastern United States. They included Byron Kilbourn of Connecticut and George H. Walker of Virginia. Kilbourn set up his own community on the west side of the Milwaukee River. Walker developed the area south of the Menomonee River. In the late 1830's, the settlements combined to form the Village of Milwaukee. Milwaukee received a city charter in 1846, and Juneau became its first mayor. By 1847, the population was about 12,000.

Beginning in the 1840's, many Europeans settled in Milwaukee. They included many Germans, Irish, and Poles. These immigrants played an important role in the city's cultural, economic, and political development.

Economic growth. During the 1850's and 1860's, Milwaukee flourished as a commercial center. Harbor improvements and the construction of roads and railroads helped the city become a leading market for flour and wheat. After 1870, manufacturing became the city's chief economic activity. With the growth of such industries as meat packing and tanning, Milwaukee's population rose to more than 200,000 by 1890.

The 1900's. Industrialization provided a base for the Socialist movement of the late 1800's and 1900's. Milwaukee Socialists did little to promote socialism, which calls for public ownership of industry. They fought for labor and political reforms and higher social benefits.

In 1910, Milwaukeeans elected Emil Seidel, a Socialist, as mayor. Milwaukee was the first major city in the United States to have a Socialist mayor. Seidel served until 1912. Since then, Milwaukee has had two other Socialist mayors—Daniel W. Hoan, from 1916 to 1940, and Frank P. Zeidler, from 1948 to 1960. The Common Council had a Socialist majority only under Seidel.

After World War II (1939-1945), Milwaukee began a redevelopment program that included construction of freeways and major changes in the downtown and lakefront areas. During the 1950's, the city modernized its harbor to receive ocean ships. These improvements and the opening of the St. Lawrence Seaway in 1959 made Milwaukee an important international port.

Both before and after World War II, Milwaukee's population grew steadily. By 1960, it reached 741,324.

In 1968, Milwaukee launched Midtown, an urban renewal project that included industrial, recreational, and residential redevelopment of an area northwest of downtown. The project ended in 1977. In the early 1980's, the Grand Avenue revitalization program focused on the downtown area. This project, completed in 1982, included the reconstruction of older buildings, construction of new ones, and the creation of an enclosed shopping mall. During the 1970's and 1980's, many people moved to new residential areas outside the city. Milwaukee's population fell to 628,088 by 1990, but some areas outside the city experienced sharp growth.

The 2000's. By 2000, Milwaukee's population had dropped to 596,974. But the population of the metropolitan area continued to grow. Michael Juley

Milwaukee Deep. See Deep.

Mimeograph. See Duplicator.

Mimicry, *MIHM ihk ree,* is the condition in which one living organism closely resembles, or mimics, its surroundings or another animal or plant. It is usually the result of similar color or construction. Mimicry may enable the organism to protect itself in its struggle for existence. For example, the monarch butterfly and the viceroy butterfly resemble each other in size, shape, and colors. The monarch is believed to be distasteful to birds, while the viceroy is not. But the viceroy often escapes being eaten by birds because it resembles the monarch.

Another example of mimicry is the *Kallima,* or "dead leaf," butterfly of India, which brings its wings together over its back and places the "tails" of its wings against a twig when it rests. The Kallima escapes notice because the undersides of its wings resemble a dead leaf in color and texture. George B. Johnson

The mimosa is a spreading tree with featherlike leaves and blossoms. Mimosas generally grow in warm climates.

Mimosa, *mih MOH suh* or *mih MOH zuh,* is the name of a group of trees, shrubs, and herbs that have featherlike leaves. Minosas grow chiefly in warm or tropical regions. In the United States, they are found from Maryland to Florida and west to Texas. The seeds of mimosas grow in flat pods. The small flowers may be white, pink, lavender, or purple. The *silver wattle,* a shrub with silvery-gray leaves, is widely sold by florists as mimosa. It is closely related to mimosas. See also Sensitive plant.

Walter S. Judd

Scientific classification. Mimosas belong to the pea family, Fabaceae or Leguminosae.

Minamoto Yoritomo, *MEE nah moh toh yoh REE toh moh* (1147-1199), was the greatest leader of early medieval Japan. He founded Japan's first *shogunate* (warrior government) in 1192.

Yoritomo was born into the aristocratic Minamoto clan. In 1180, he broke relations with the imperial court at Kyoto, then the capital of Japan, and was drawn into a war with a clan much like his own. The Minamoto clan defeated the Taira clan in the Gempei War (1180-1185). Yoritomo, the Minamoto clan leader, established a military headquarters at the city of Kamakura. The emperor gave Yoritomo the title of *shogun* (great general), and Yoritomo's headquarters became the administrative center of the shogunate. Yoritomo formed a system of civil and military rule in cooperation with the Kyoto court. His rule led to a balance of power and influence between Kamakura and Kyoto that provided relative peace and stability for almost 150 years. Jeffrey P. Mass

Minaret, *MIHN uh REHT* or *MIHN uh reht,* is a tall, usually slender, tower attached to the Muslim house of worship, called a *mosque.* Most mosques have from two to six minarets. From the top of the minaret, a *muezzin* (crier) calls the faithful to prayer five times each day. Minarets have one or more balconies where the muezzin can stand. The minaret may be round, square, or many-sided. Most are built of brick or stone, and contain an internal staircase. The minaret is one of the most common features of Islamic architecture.

© R. & S. Michaud, Woodfin Camp, Inc.

Minarets are towers attached to Islamic houses of worship called *mosques.* A crier called a *muezzin* summons Muslims to prayer from a balcony near the top of the minaret.

Many scholars believe the form of the minaret is derived from the ancient Lighthouse at Alexandria, Egypt, which was completed in the 200's B.C. Among the earliest minarets are those at a mosque in Damascus, Syria, built in A.D. 707. Minarets are common in India, northern Africa, and the Middle East. William J. Hennessey

Minch, The, is a broad strait that separates the island of Lewis with Harris, in the Outer Hebrides, from the west coast of Scotland. For location, see Scotland (political map). The average width of the strait is about 30 miles (48 kilometers). A. S. Mather

Mind. Psychologists, psychiatrists, and philosophers have held many views on the nature of the mind. Even today, they still disagree.

Early theories of mind held that human beings were made up of two different substances, *mind* and *matter.* Matter was something that could be seen and felt. Matter occupied space and had weight. Mind was a substance present in a person, but it took up no space and could not be weighed, seen, or touched. The mind was divided into several *faculties,* such as will, reason, and memory. Some people thought that the mind, like the muscles, developed through exercise. Thus, the way to strengthen the mind was to give the faculties work to do.

Some psychologists and philosophers who questioned the mind-substance idea offered the view that mind was the sum total of all a person's conscious states. This meant that the mind was simply a mass of thoughts, memories, feelings, and emotions. At any given moment, there would be only a few things in a person's consciousness, the things to which a person was giving attention; and there would be some other things of which a person was aware without thinking about them, somewhat as we see things "out of the corner of our eye." Below this level of consciousness would be a whole vast mass made up of all the conscious states an individual had experienced since birth. When-

ever a new idea or impression entered a person's consciousness, all earlier impressions like it or related to it would rise up into awareness. By continuously responding to new experiences in this way, the mind would keep enriching and rearranging itself.

The nature of mind. During the 1800's, some psychologists experimented to test ideas about the nature of mind. For example, one experimenter explored the question of whether mental effort strengthened the mind. He repeatedly memorized nonsense syllables, then checked whether the time required to remember them decreased with each attempt. When the time stayed about the same, he concluded that practice memorizing did not improve memory. Other psychologists questioned why—if mind and matter were separate—physical influences such as drugs, illness, or a blow on the head could greatly affect a person's mind. Observers also wondered why many people's minds failed along with their bodies in extreme old age.

Some psychologists claimed that everything about a person could be explained in terms of the body without using the idea of "mind" at all. These psychologists thought that "mental" events would one day be shown to result from physical processes in the brain and nervous system.

Still other psychologists developed the idea that mind is a quality that *emerges* (comes into being) from a complex arrangement of physical parts lacking that quality themselves. Another example of such a quality is wetness. Wetness "emerges" from the large numbers of hydrogen and oxygen atoms that make up water even though the individual atoms themselves are not wet.

The mind-body problem. The question of the nature of mind and its relationship to the physical world is often expressed as the concept of the *mind-body problem.* Common sense tells us that everyone has both a mind and a body that work together. For example, many thoughts or feelings include physical reactions. Pleasure can make people smile, and fear can make people tremble. Our everyday experience also shows us ways that the body influences the mind. People notice differences in their mental state depending on whether they are hungry or well fed, cold or warm, sick or well. Scientists have also discovered that certain glands have strong effects on emotions and behavior. See **Behavior.**

But the mind also acts in ways in which its relationship to the body is less clear. For example, you might daydream at a boring meeting, but nothing about your body would alert other people that you were not paying attention. Although philosophers and scientists have explored the mind-body problem for centuries, nobody has yet explained exactly how the mind and body work together. Nancy C. Andreasen

Mind reading is a term loosely applied to various forms of *extrasensory perception* (ESP), especially *telepathy* and *clairvoyance.* Telepathy is an awareness of another person's thoughts, knowledge, or feelings without the aid of the senses of hearing, sight, smell, taste, or touch. Clairvoyance is an awareness of events, objects, or persons without the use of the known senses. The term *mind reading* may be considered a synonym for *telepathy.* But the term has little more than historical interest today because of changing ideas about the concept of the mind. In the past, each person was considered to have a mind more or less independent of his body and behavior. It was also thought that one mind could "read" another mind without using the known senses. Today, scientists do not believe that the mind is independent of the rest of the body. William M. Smith

Mindoro. See **Philippines** (The main islands).

Mindszenty, *mihnd ZEHN tih,* **Joseph Cardinal** (1892-1975), a cardinal of the Roman Catholic Church, was a religious leader in Hungary. For many people, he became a symbol of resistance to Communism.

Pope Pius XII named Mindszenty bishop of Veszprém in 1944, and archbishop of Esztergom and primate of Hungary in 1945. The pope made him a cardinal in 1946. Mindszenty became a main target of the Communist-dominated secret police. In 1949, Mindszenty was convicted of treason by Hungary's Communist government and given a life sentence. He remained under house arrest until 1956, when Hungarian rebels freed him during their revolt. Mindszenty took refuge in the United States Embassy in Budapest and lived there for 15 years.

United Press Int.
Cardinal Mindszenty

In 1971, Mindszenty left Hungary and went into exile in Rome. He did so at the request of Pope Paul VI, under an agreement between the Vatican and the Hungarian government. Mindszenty later settled in Vienna. In 1974, to improve relations between the church and the Hungarian government, the pope removed Mindszenty as primate of Hungary and archbishop of Esztergom.

Mindszenty was born Joseph Pehm in Csehimindszenty. His father was of German ancestry. Mindszenty was ordained a priest in 1915. During the Nazi occupation of Hungary, he changed his name to indicate his complete Hungarian nationality, using the name of his birthplace. John T. Farrell

Mine. See **Mining.**

Mine warfare is the use of explosive devices called mines to kill enemy troops and destroy their ships, tanks, and other equipment. Some mines explode when a person steps on them. Others explode when run over by a tank or jeep. Mines may be designed to explode when moved or even touched. Naval mines are *detonated* (exploded) by the effects produced by a passing ship. Mines also may be exploded by remote control.

Mines can be positioned to prevent an enemy from entering an area. They can also be used to influence the course traveled by enemy troops or ships. By avoiding mined areas, enemy forces may be forced to take routes where they can be attacked more easily. Mines are inexpensive compared to many other weapons, and persons with little training can put them into place.

There are two chief kinds of mines, *land mines* and *naval mines.*

Land mines

Land mines are planted in the ground. They may be laid out in planned patterns called *mine fields.* Mines may be planted by soldiers or fired into an area by artillery. They also may be dropped by helicopters.

Kinds of land mines. The main types of land mines are (1) antipersonnel mines, (2) antitank mines, (3) chemical mines, (4) controlled mines, and (5) nuclear mines.

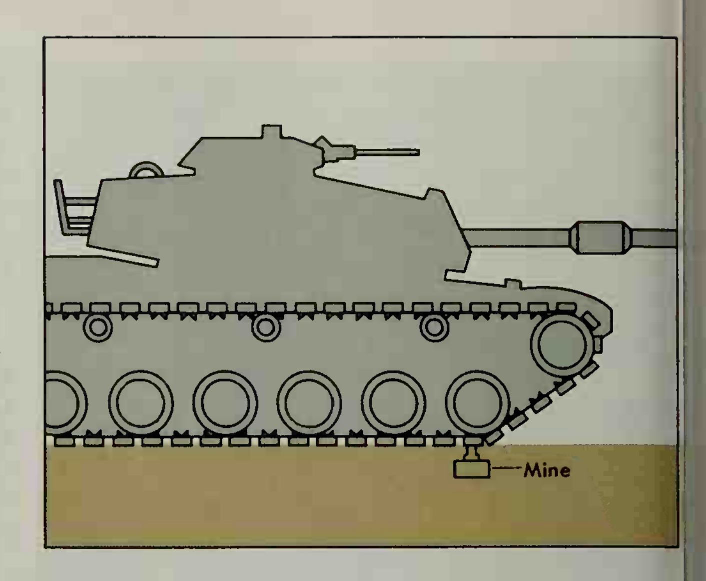
Antipersonnel mines are used to kill or injure enemy soldiers. They have a sensitive *fuse* (triggering device) that is set off by the weight of even a small person. They also may be set off when someone walks into a wire or moves an object to which the mines are wired.

Some antipersonnel mines have small explosive charges and kill only a few persons a short distance away. Others can kill many people more than 200 yards (180 meters) away. Some antipersonnel mines fire an explosive charge that explodes in the air, spraying shrapnel over a large area (see **Shrapnel**).

Mines called *booby traps* explode when they are moved. They are hidden in buildings; under dead soldiers; or in ordinary objects, such as appliances and briefcases, that are likely to be moved by enemy troops.

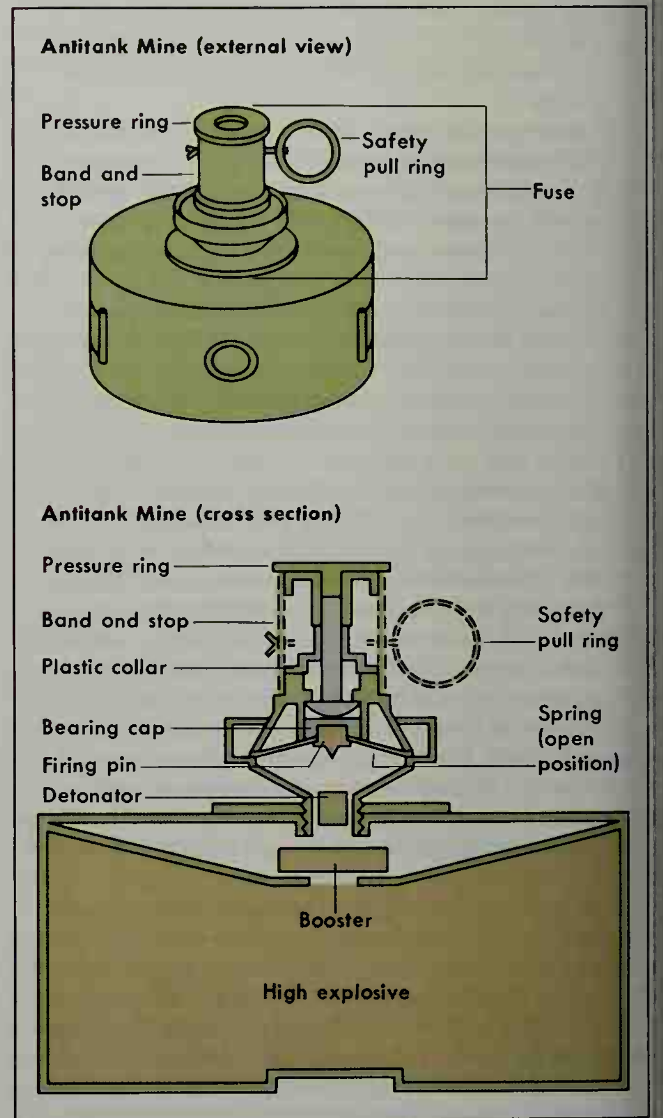
Antitank mines destroy enemy tanks and other vehicles. These mines are larger than antipersonnel mines. Most types of antitank mines explode only when a weight of more than about 300 pounds (140 kilograms) moves over them. Soldiers can walk safely on antitank mines. But these mines destroy trucks and lightly armored vehicles and at least damage the metal tracks on which tanks move.

Chemical mines release a poison gas when they are triggered. The gas kills or injures unprotected troops.



Controlled mines are placed in position before a battle. They are exploded by remote control when enemy forces approach the mines.

Nuclear mines contain small nuclear devices. These mines are used to blow up concrete bridges or to close off mountain passes. Such jobs would require many tons of conventional explosives. Nuclear mines are small enough to be carried by two persons or in a jeep.



Detecting land mines. Land mines can be detected by several methods. Soldiers may locate mines by crawling along the ground and carefully probing the area ahead with their bayonets. When a mine is found, it is cautiously dug out and the fuse is removed, or its position is marked so it can be bypassed. Sensitive instruments called *mine detectors* locate mines with metal cases. Mines can be detected more rapidly by a mine-detecting device mounted on a jeep. The jeep stops automatically when the device detects a mine.

After mines have been detected, they may be marked and bypassed, exploded by artillery fire, or blown up by tanks fitted with special rollers or chain devices. The devices trigger the mines when passing over them. Devices called *snakes* are also used to clear minefields. Snakes are long tubes packed with explosives that are detonated in a mined area. The blast sets off nearby mines and clears a path for troops and vehicles.

Efforts to ban land mines. Every year, thousands of people are killed or maimed by antipersonnel land

An antitank mine explodes when run over by a tank or other heavy vehicle. The mine, which is buried close to the surface, is triggered by the pressure of the vehicle.

WORLD BOOK diagrams by Steven Liska

The parts of an antitank mine are shown in this diagram. The mine is detonated when the pressure ring at the top is forced down into the mine. This action causes the firing pin to hit the detonator, which then sets off the booster. The booster then activates the high explosive, and the mine explodes.

mines. The vast majority are civilians who come into contact with mines planted years ago and left behind long after the fighting stopped. In the early 1990's, several organizations began calling for a global ban on antipersonnel land mines. One such organization, the International Campaign to Ban Land Mines, won the Nobel Peace Prize in 1997 for its efforts. In December 1997, an international treaty was introduced calling for a worldwide ban on antipersonnel mines. In March 1999, the treaty went into force. At that time, more than 130 countries had signed the treaty and 65 had *ratified* (approved) it. But other countries consider the mines an important defensive weapon and have refused to sign the treaty.

Naval mines

Naval mines rest on or are anchored to the floor of a body of water. Some naval mines float freely, but such mines are dangerous to friendly ships as well as enemy vessels. Naval mines are laid by surface ships, including vessels called *minelayers,* and by aircraft and submarines. Some naval mines are self-propelled. They are launched from a submarine and travel a few miles before settling on the ocean floor. The CAPTOR mine of the United States Navy is anchored to the ocean bottom. The mine launches a self-guided torpedo after detecting the propeller noise of a passing submarine.

Kinds of naval mines. There are four chief kinds of naval mines. They are (1) acoustic mines, (2) contact mines, (3) magnetic mines, and (4) pressure mines.

Acoustic mines are exploded by the sound of a ship's propellers.

Contact mines are triggered when a ship touches them. They also may be exploded when a ship touches antennas that stick out from the mines.

Magnetic mines are triggered by the magnetic field that surrounds a metal warship. To avoid setting off a magnetic mine, a ship may use a set of electrical cables called a *degaussing belt,* which reduces or neutralizes the magnetic field.

Pressure mines explode when passing ships cause a change in the water pressure around the mines.

Detecting naval mines. Naval mines are difficult to detect and to *sweep* (remove or detonate). They may be fitted with counting devices that allow a certain number of ships to pass before the mines explode. The mines may also be fitted with timers that prevent them from firing for a certain number of hours or days. Ships called *minesweepers* use sonar to locate mines, which are then swept. Minesweeping helicopters tow devices that sweep mines in shallow water. Ships called *minehunters* operate cable-controlled vehicles that examine and destroy mines on the ocean floor.

Acoustic mines are blown up by noisemaking devices towed underwater. The anchor cables of contact mines are cut by instruments towed underwater by minesweepers. The mines then float to the surface and are exploded by gunfire. Some magnetic mines are triggered by electrical devices towed by ships. Pressure mines are cleared by having a small, specially equipped ship pass nearby to detonate them.

History

Land mines have been used in warfare for more than 200 years. The term *mine* came from the practice of digging tunnels under enemy positions, packing the tunnels with gunpowder, and exploding them. During the American Civil War (1861-1865), Union soldiers mined a section of Confederate trenches at Petersburg, Virginia. The soldiers dug a tunnel over 500 feet (150 meters) long, placed gunpowder in it, and blew a large crater in the Confederate defenses. During World War I (1914-1918), troops buried artillery shells that exploded when stepped on by a person or run over by a tank or truck. After World War I, mines with wood, metal, or plastic containers were developed. Land mines were widely used during World War II (1939-1945) and later wars.

The first naval mines—floating vessels that contained explosives—were used during the late 1500's. Early types of underwater mines, called *torpedoes,* were sealed wood containers filled with gunpowder and equipped with a fuse. The fuse was set, and a diver swam under an enemy ship and attached the torpedo to the ship's hull. During the Revolutionary War in America (1775-1783), David Bushnell, an American inventor, developed the first American submarine equipped with a mine-attaching device. During the Civil War, both the Confederate Navy and the Union Navy used underwater mines. Naval mines were also used extensively in most later wars. Norman Polmar

Miner. See Mining; Coal (How coal is mined; The coal industry [picture: Coal miners]).

Miner, Jack (1865-1944), was a Canadian bird conservationist and researcher of North American bird migrations. He established a bird sanctuary on his farm near Kingsville, Ontario, in 1904. Miner studied the migrations of ducks and geese by marking thousands of them with numbered metal leg bands, then releasing them. Hunters returned the bands from birds they shot. In this way, Miner learned where the migrating birds went. Friends set up the Jack Miner Migratory Bird Foundation in 1931 to continue the research. Miner was born John Thomas Miner in Dover Center, Ohio. G. J. Kenagy

Quartz

Mica

Rocks are made of minerals. A chunk of granite, *left,* contains bits of hornblende, feldspar, quartz, and mica. Alone, these minerals appear as shown, *right.*

Mineral

Mineral is the most common solid material found on the earth. The earth's land and oceans all rest on a layer of rock made of minerals. Rocks on the earth's surface are also made of minerals. Even soil contains tiny pieces of minerals broken from rocks. Minerals are also found on our moon and on Mercury, Venus, and Mars.

Minerals include such common substances as rock salt and pencil "lead," and such rare ones as gold, silver, and gems. There are about 3,000 kinds of minerals, but only about 100 of them are common. Most of the others are harder to find than gold.

People use minerals to make many products. For example, graphite is used for pencil leads. Other products made from minerals include cement for building, fertilizers for farming, and chemicals for manufacturing.

Many people use the term *mineral* for any substance taken from the earth. Such substances include coal, petroleum, natural gas, and sand—none of which is a mineral. However, these substances are commonly known as mineral resources. Certain substances in food and water, such as calcium, iron, and phosphorus, also are called minerals. But mineralogists, the scientists who study minerals, do not consider any of them minerals.

Mineralogists use the term *mineral* to mean a substance that has all of the four following features. (1) A mineral is found in nature. A natural diamond is a mineral, but a synthetic diamond is not. (2) A mineral has the same chemical makeup wherever it is found. Sand is not a mineral because samples from different places usually have different chemical makeups. They are mixtures. (3) The atoms of a mineral are arranged in a regular pattern, and form solid units called *crystals.* The calcium and phosphorus found in milk are not minerals because they are dissolved in a liquid and are not crystals. (4) With some exceptions, a mineral is made up of substances that were never alive. Coal, petroleum, and natural gas are not minerals partly because they were formed from the remains of animals and plants. In addition, coal is not a mineral because it does not have a consistent chemical makeup. Furthermore, petroleum and natural gas are not minerals because they are not solids. The exceptions—minerals that are made up of substances that were once alive—have undergone a transformation by inorganic processes over many years. One example is calcite.

This article discusses only substances that mineralogists consider minerals. For information on coal, oil, and other products taken from the ground, see **Mining** with its list of *Related articles.* For information on other materials that are often called minerals, see **Nutrition** (Minerals) and **Ocean** (Minerals).

Identifying minerals

Minerals vary greatly in appearance and feel. Some minerals have glasslike surfaces that sparkle with color.

David F. Hess, the contributor of this article, is Associate Professor of Geology at Western Illinois University. All photos are courtesy of the Field Museum in Chicago unless otherwise noted.

Others look dull and feel greasy. The hardest minerals can scratch glass. The softest ones can be scratched by a fingernail. Four of the main characteristics of minerals are (1) luster, (2) cleavage, (3) hardness, and (4) color.

Luster of a mineral may be metallic or nonmetallic. Minerals with metallic luster shine like metal. Such minerals include galena, gold, and ilmenite. Minerals with nonmetallic luster vary in appearance. Quartz looks glassy, talc has a pearly surface, and varieties of cinnabar appear dull and claylike. The luster of a mineral also may differ from sample to sample. Some cinnabar, for example, has a metallic luster rather than a dull luster.

Cleavage is the splitting of a mineral into pieces that have flat surfaces. Minerals differ in the number of directions they split, and in the angles at which the flat surfaces meet. Mica splits in one direction and forms thin sheets. Halite has three cleavage directions, and it breaks into tiny cubes. A diamond may split in four directions, forming a pyramid. Other minerals, such as quartz, do not split cleanly, but break into pieces with irregular surfaces.

Hardness of minerals may be tested by scratching one mineral with another. The harder mineral scratches the softer one, and mineralogists use a scale of hardness based on this principle. Friedrich Mohs, a German mineralogist, invented the scale in 1822. The Mohs hardness scale lists 10 minerals from the softest to the hardest. These minerals are numbered from 1 to 10. The hardness of other minerals is found by determining whether they scratch, or are scratched by, the minerals in the Mohs scale. For example, galena scratches gypsum (number 2), but is scratched by calcite (number 3). Therefore, galena's hardness is $2\frac{1}{2}$—about halfway between that of gypsum and calcite. A person's fingernail has a hardness of about 2.

Color of some minerals depends on the substances that make up the crystals. The black of ilmenite, the red of cinnabar, and the green of serpentine all result from the chemical composition of these minerals. Other minerals get their color from chemical impurities. Pure quartz, for example, has colorless crystals. But tiny amounts of other substances in quartz crystals can give quartz a pink or green tint, or even make it black.

Other identification tests. Some minerals may be recognized by their *habit* (general appearance). Gold is found in the form of nuggets, and diamonds are found as crystals. Halite may have the form of grains, clumps of crystals, or large chunks. Serpentine asbestos occurs as fibers. Mineralogists can also identify minerals by feeling, tasting, or smelling them. Talc and serpentine feel greasy. Epsomite and halite taste salty, and borax and melanterite taste sweet. Kaolinite has an earthy smell.

A *streak test* uses color to identify a mineral. The mineral is rubbed across a slightly rough, white porcelain plate. The rubbing grinds some of the mineral to powder and leaves a colored streak on the plate. But the streak is not always the same color as the sample. Hematite varies from reddish brown to black, but always leaves a red streak. Chalcopyrite, a brassy yellow mineral, produces a green-black streak.

Many chemical tests can identify minerals. One of the simplest consists of pouring a warm, dilute acid on the sample. If the acid fizzes, the sample belongs to a group of minerals called *carbonates.* Calcite, aragonite, and dolomite are carbonates. These minerals contain carbon and oxygen, together with other chemicals. When attacked by acid, the minerals release carbon dioxide gas which forms bubbles in the acid. This test may be made at home, using vinegar for the acid. In the *flame test,* a bit of a mineral is ground into powder near the air holes at the base of a lighted Bunsen burner. Air carries the powder up into the flame. The powder gives the flame a color that identifies the mineral.

Inside minerals

Mineral crystals occur in many sizes. A giant crystal of beryl or feldspar may weigh several tons. Tiny crystals of kaolin may be too small to be studied even with a microscope. Regardless of their size, all crystals are basically the same. They are groups of atoms arranged in a

Mohs Hardness Scale

Mineral	Hardness	Common Tests
Talc	1	Scratched by a fingernail
Gypsum	2	
Calcite	3	Scratched by a copper coin
Fluorite	4	Scratched by a knife blade or window glass
Apatite	5	
Feldspar	6	Scratches a knife blade or window glass
Quartz	7	
Topaz	8	
Corundum	9	
Diamond	10	Scratches all common materials

Common identification tests. A mineral's hardness is tested by scratching it against minerals listed in the Mohs scale, *left.* A streak test of hematite, *center,* leaves a red streak. The tester rubs the mineral against rough porcelain and wipes the streak with his finger. *Right,* calcite cleaves into blocks, and mica into sheets.

Common minerals with metallic luster

Bornite Cu_5FeS_4. Copper-red with purple-blue tarnish. Hardness 3. Cleaves.

Chalcopyrite $CuFeS_2$. Brassy yellow. Leaves a green-black streak. Hardness $3\frac{1}{2}$-4. Does not cleave.

Copper Cu. Copper-red with brown tarnish. Hardness $2\frac{1}{2}$-3. Does not cleave.

Galena PbS. Bright metallic lead-gray cubes. Hardness $2\frac{1}{2}$. Cleaves to form cubes.

Gold Au. Yellow nuggets, grains, and flakes. Does not tarnish. Hardness $2\frac{1}{2}$-3. Does not cleave.

Graphite C. Steel-gray. Feels greasy. Hardness 1-2. Cleaves into tablets and sheets.

Magnetite Fe_3O_4. Black. Attracted by magnet and may act as magnet. Hardness $5\frac{1}{2}$-$6\frac{1}{2}$. Does not cleave.

Pyrite FeS_2. Pale brassy yellow. Leaves green- to brown-black streak. Hardness 6-$6\frac{1}{2}$. Does not cleave.

Pyrrhotite FeS. Bronze-yellow. Weakly attracted to magnet. Hardness $3\frac{1}{2}$-$4\frac{1}{2}$. Does not cleave.

Rutile TiO_2. Red to black with gem-like luster. Hardness 6-$6\frac{1}{2}$. Cleaves.

Silver Ag. Silver-white (above, as flecks in barite), tarnishing to black. Hardness $2\frac{1}{2}$-3. Does not cleave.

Stibnite Sb_2S_3. Gray columns with black tarnish. Hardness 2. Cleaves in one direction.

Common minerals with nonmetallic luster

Almandine, a garnet, $Fe_3Al_2Si_3O_{12}$. Deep red, brownish-red, or brownish-black. Hardness 7-7½. Does not cleave.

Azurite $Cu_3(CO_3)_2(OH)_2$. Blue. Hardness 3½-4. Cleaves irregularly.

Calcite $CaCO_3$. Colorless or white when pure. Hardness 3. Rhombohedral cleavage.

Fluorite CaF_2. Green, blue, or purple cubes. Hardness 4. Cleaves in four directions.

Gypsum $CaSO_4{\cdot}2H_2O$. Colorless, white, gray, or yellow to brown. Hardness 2. Cleaves into plates.

Kyanite Al_2SiO_5. Often, pale blue to white. Hardness 4-7½. Cleaves in one direction.

Malachite $Cu_2(CO_3)(OH)_2$. Bright green. Hardness 3½-4. Cleaves irregularly.

Muscovite $KAl_2(AlSi_3O_{10})(OH)_2$. Colorless. Hardness 2½-3. Cleaves into tablets and sheets.

Potassium feldspar $KAlSi_3O_8$. White to pink. Hardness 6. Cleaves almost at right angles.

Quartz SiO_2. Clear or tinted glassy crystals. Hardness 7. Does not cleave.

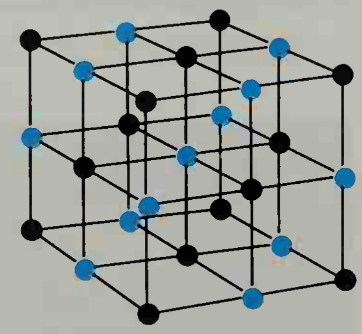
Sulfur S. Yellow. Melts and burns with a match. Hardness 1½-2½. Cleaves irregularly.

Talc $Mg_3Si_4O_{10}(OH)_2$. White, green, or gray. Feels greasy. Hardness 1. Cleaves into tablets and sheets.

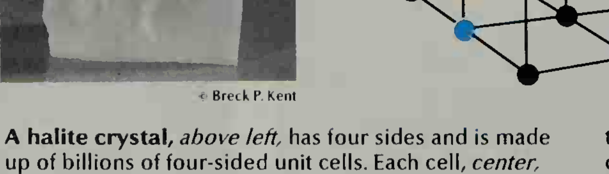
regular pattern. To imagine what it is like inside a crystal, you can think of "rooms" formed by the crystal's atoms. A room in a copper crystal is formed by 14 copper atoms. The room has an atom at each corner of the floor and ceiling, and an atom at the centers of the floor, the ceiling, and each of the four walls. A copper crystal consists of many rooms side by side and one on top of the other. The rooms share copper atoms where they meet. Mineralogists call such rooms *unit cells.*

Most minerals consist of more than one kind of atom. Halite, for example, consists of sodium atoms and chlorine atoms. Other minerals may have as many as five kinds of atoms in complicated arrangements. Some unit cells have six walls instead of four, and others have slanted walls. Such differences in the shape of unit cells produce differences in the shape of mineral crystals.

Chemical bonds are electrical forces that hold atoms together in a crystal. An *ionic bond* results when certain atoms give up some of their electrons to other atoms. Ionic bonds are the most common chemical bond in minerals. A *covalent bond* results when several atoms share electrons. Covalent bonds, which are very strong, occur in such minerals as diamonds, and are common in compounds containing carbon. Chemical bonds can hold two or more atoms together only in definite positions. These positions depend on the size of the atoms, and the number of bonding electrons. The shape and size of the unit cell, in turn, depend on the positions the atoms take when they are bonded together. See **Bond**.



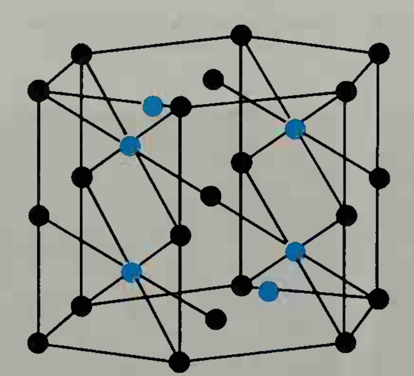
Bonds between atoms are not all equally strong. This variation in bonding strength explains why some crystals can be cleaved. Cleavage can take place in a crystal when the weak bonds lie at a right angle to a flat surface that is called a *cleavage plane.* When the crystal is cut along the cleavage plane, the weak bonds break and the crystal splits, exposing the flat surface.

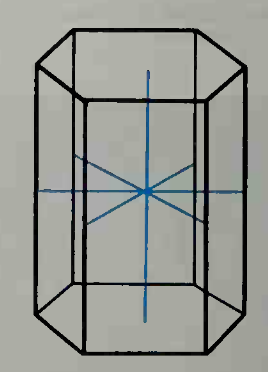


How minerals grow. Most minerals grow in liquids. For example, some crystals grow in a liquid called *magma* deep inside the earth. This extremely hot substance contains all the kinds of atoms that make up the earth's minerals. When magma cools, some atoms become bonded together and form tiny crystals. The crystals grow by adding layers of atoms to their flat outer surfaces. The new atoms must be the right size, and they must have the right number of bonding electrons to fit into the growing crystals.

Mineral composition and structure are both important in studying and classifying minerals. Some minerals have the same kind of crystal, but differ in one or more of the atoms that make it up. For example, olivine has a basic crystal made of oxygen and silicon atoms. Either iron or magnesium atoms can fit into this crystal. As

How atoms are arranged in minerals





© Breck P. Kent

A halite crystal, *above left,* has four sides and is made up of billions of four-sided unit cells. Each cell, *center,* contains 14 sodium atoms (shown in black) and 13 chlorine atoms (blue). Halite belongs to the isometric crystal system—one of seven systems into which all mineral crystals are grouped. A diagram for the isometric system, *right,* includes three axes (imaginary lines) that show the directions followed by the crystal's edges.

© Breck P. Kent

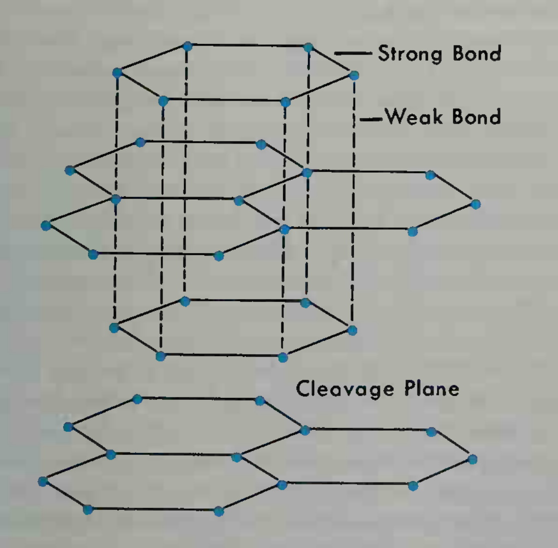
A corundum crystal, *above left,* has six sides. Its unit cell, *center,* is a six-sided "room" containing 21 oxygen atoms (black) and 6 aluminum atoms (blue). Corundum is in the hexagonal system, *right,* which has four axes.

a result, there are two kinds of olivine—forsterite, which contains magnesium, and fayalite, which contains iron. Mineralogists use the term *isomorphic* for minerals that have the same structure but different compositions.

Some mineral crystals are made of the same kinds of atoms, but differ in the way the atoms are arranged. For example, diamond and graphite are both made of the element carbon. The carbon in diamond, which is the hardest substance known, is bonded into a blocky framework. The carbon in graphite is bonded into thin, fragile sheets. Mineralogists use the term *polymorphic* to describe minerals that have the same composition but different structures.

The major *classes* of minerals—based on composition and structure—include *elements, sulfides, halides, carbonates, sulfates, oxides, phosphates, and silicates.* The silicate class is especially important, because silicates make up 95 per cent of the minerals, by volume, in the earth's crust. Mineral classes are divided into *families* on the basis of the chemicals in each mineral. Families, in turn, are made up of *groups* of minerals that have a similar structure. Groups are further divided into *species.*

History of mineralogy



Early studies. Minerals were among the first substances that people used and described. Egyptian paintings of 5,000 years ago show that minerals were used in weapons and jewelry, and in religious ceremonies. Theophrastus, a Greek philosopher, wrote a short work on minerals about 300 B.C. Pliny the Elder of Rome wrote about metals, ores, stones, and gems about A.D. 77. Other early writings about minerals were done by German scientists. These writings include *De Mineralibus* (1262) by Albertus Magnus and *De Re Metallica* (1556) by Georgius Agricola.

Why some minerals cleave

E. R. Degginger

Graphite, *above,* consists of layers of carbon atoms. Weak bonds hold the layers together and form cleavage planes, *below.* The crystal splits into tablets along these planes.

The scientific study of mineral crystals began in the 1600's. In 1665, Robert Hooke, an English scientist, showed that metal balls piled in different ways duplicated the shapes of alum crystals. In 1669, Nicolaus Steno, a Danish physician, found that the angles between the faces of quartz crystals were always the same, even though the crystals had different shapes.

By the late 1700's, scientists had studied and described many minerals. But they only guessed at the makeup of crystals and the reasons for their shape. A French scientist, Romé de l'Isle, suggested in 1772 that Steno's discovery could be explained only if the crystals were composed of identical units stacked together in a regular way. During the 1780's, the French scientist René J. Haüy made further studies of these mineral units. He called them *integral molecules.* About 1780, chemists began to develop clearer ideas about the nature of chemical elements. Mineralogists then saw that minerals were made up of chemicals, but they still did not understand their structure.

Determining the structure of crystals. In the 1900's, X-ray studies provided the key to the internal structure of minerals. In 1912, German scientist Max von Laue sent an X-ray beam through a crystal of sphalerite. The beam was *diffracted* (divided) by the flat surfaces of the crystal. The experiment showed that the atoms in sphalerite are bonded together into sheets which connect to one another at specific angles. From similar experiments, scientists later learned how atoms are arranged into unit cells and, in turn, into crystals. By the 1930's, scientists had used X rays to study and describe many different types of minerals.

Today, new laboratory instruments are changing the study of minerals. The *electron probe microanalyzer,* linked to a computer, can measure changes in the chemical composition of a single crystal. A *scanning electron microscope* magnifies crystals many thousands of times beyond normal size. Using a special electron microscope, scientists can photograph the shadows or reflections of atoms and molecules. In this way they can view the internal structure of a crystal. David F. Hess

Mineral oil is a clear, colorless, oily liquid that has almost no taste or odor. It is also called *liquid paraffin, liquid petrolatum, white mineral oil,* and *white paraffin oil.* Mineral oil is an ingredient in certain medicines and cosmetics. The liquid also serves as a dissolving agent in the manufacture of plastics, and as an industrial lubricant. Mineral oil comes from the distillation of petroleum *fractions* (separated parts) at 600 to 750 °F (316 to 399 °C). Further refinement purifies the oil. See also **Distillation.** Geoffrey E. Dolbear

Mineral water, also called *aerated water,* is spring water that has a high content of mineral matter or of gas. (The term *aerated* means *charged with gas.*) The mineral matter includes salt, Epsom salt, lime, magnesia, iron, silica, boron, fluorine, and many others, including radioactive substances. The most common gases in mineral water are carbon dioxide and hydrogen sulfide.

In most cases, the water is rainwater that has seeped underground through rocks, dissolving mineral matter on the way. Other springs may contain *magmatic* or *juvenile* water, which rises from deep in the earth after forming through a chemical process in rocks. Some of these springs are hot springs. Others have cooled to ordinary temperatures.

People have used mineral water since ancient times to cure such ailments as rheumatism, skin infections, and poor digestion. The temperature of the water, the location, the altitude, and the climate at the springs are all considered in the treatment.

There are thousands of mineral springs in North America. About 800 have at one time had *spas* (resorts) where people used to come for the waters. Most of them are in the East and Midwest. Their popularity has declined since the early 1900's, and many have shut down. The best-known mineral springs today are at Saratoga Springs, New York; Hot Springs, Arkansas; and French Lick, Indiana (see **Hot Springs National Park**).

The waters from some foreign springs are imported to the United States. Among these waters are the Apollinaris from Germany, Hunyadi-Janos from Hungary, and Vichy from France. Water taken from mineral springs is sold in sterilized bottles. Douglas S. Cherkauer

Minerva was one of the most important goddesses in ancient Roman mythology. Minerva resembled the Greek goddess Athena and, like her, was a virgin goddess. She was the favorite child of Jupiter, the king of the gods. One myth tells of her being born out of Jupiter's head, fully grown and dressed in armor.

Minerva had a variety of functions. Originally, she represented skill in handicrafts, particularly those associated with women, such as spinning and weaving. Later, Minerva came to symbolize general skill. Still later, the Romans worshiped her as the goddess of wisdom. The owl has traditionally been considered wise because it was the bird of Minerva.

The Romans, who believed warfare involved the higher mental powers, worshiped Minerva as goddess of the intellectual aspect of war. Most artists showed her wearing armor and a helmet. Minerva carried a magic shield or breastplate called the *aegis.* E. N. Genovese

Mineta, Norman Yoshio (1931-), is United States secretary of transportation. President George W. Bush named Mineta to the Cabinet post in 2001. From 2000 to 2001, Mineta had served as secretary of commerce under President Bill Clinton. Mineta is the first Asian American to be appointed to the U.S. Cabinet.

Mineta, who is of Japanese descent, was born in San Jose. He was a boy in 1941 when Japan's attack on the U.S. military base at Pearl Harbor, Hawaii, brought the United States into World War II. During the war, the U.S. government confined about 110,000 Americans of Japanese ancestry in internment camps. Mineta and his family lived in a camp in Wyoming in 1942 and 1943. Mineta graduated from the University of California at Berkeley in 1953. He served in the U.S. Army from 1953 to 1956, then joined his family's insurance business. He was mayor of San Jose from 1971 to 1974.

From 1975 to 1995, Mineta served in the U.S. House of Representatives. As a representative, he helped pass the Civil Liberties Act of 1988. The act called for a national apology and a payment to surviving Japanese Americans who had been in the internment camps. From 1995 to 2000, Mineta was an executive with Lockheed Martin Corporation, an aircraft manufacturer. Lee Thornton

Ming dynasty ruled China from A.D. 1368 to 1644, a period of Chinese rule between two foreign conquests. It was preceded by the Mongol Empire and followed by the Manchu dynasty. Ming rulers restored traditional institutions, such as the civil service, which the Mongols had suspended. During the Ming period, Chinese authority extended into Mongolia, Korea, Southeast Asia, and the Ryukyu Islands.

Ming means *bright* in Chinese, and the period was important especially in the arts. The imperial palace in Beijing's *Forbidden City* reached its current splendor largely through the efforts of Ming architects. Artists also produced exquisite porcelain, bronze, and lacquerware. During the final century of the Ming dynasty, increasing numbers of Europeans began visiting China and opening it up to foreign influence. Richard L. Davis

Mingus, Charles (1922-1979), was one of the most important figures in jazz history. Mingus made contributions to the music as a bass player, composer, and bandleader. His outspoken, sometimes angry, behavior made him one of the most distinctive personalities in jazz.

Mingus was born in Nogales, Arizona, and grew up in the Watts district of Los Angeles. He gained his first national attention as a member of a trio led by vibraphone player Red Norvo in 1950. During the mid-1950's, he also worked with musicians of both swing and bebop styles. At that time he formed the Jazz Workshop, a group of musicians who played his experimental music.

Mingus established himself as a composer in the mid-1950's. His first important album was *Pithecanthropus Erectus* (1956). Mingus recorded his most significant compositions soon afterward, including "Fables of Faubus," "Goodbye Pork Pie Hat," "Better Git It in Your Soul," "Far Wells, Mill Valley," and "Wednesday Night Prayer Meeting." The compositions were a striking blend of blues, gospel, bebop, and elements of the experimental style called *free jazz.* The music featured shifting tempos, overlapping passages, and dense textures.

During the 1960's and 1970's, Mingus developed a kind of repertory company of musicians that included saxophonists Clifford Jordan, Booker Ervin, Jr., and Eric Dolphy; trombone player Jimmy Knepper; trumpeter Ted Curson; pianist Jaki Byard; and drummer Dannie Richmond. During his career, Mingus battled psychological problems that sometimes resulted in confrontations with audiences and musicians. He attacked racism in the United States in his erratic and controversial autobiography *Beneath the Underdog* (1971). Frank Tirro

Miniature bull terrier is a small, muscular dog. Except for its smaller size, it is identical to the bull terrier. Breeders in England developed the miniature bull terrier by mating small bull terriers to one another. The miniature bull terrier stands about 10 to 14 inches (25 to 36 centimeters) high and usually weighs 15 to 30 pounds (7 to 14 kilograms). It has a long, wide head; small eyes; pointed ears; a short, glossy coat; and a short, straight tail. Miniature bull terriers most commonly are white. They also may be gray, brown, tan, red, or other colors, usually with white markings. Miniature bull terriers are regarded as intelligent, alert, and friendly. They make good show dogs and pets. See also **Bull terrier**.

Critically reviewed by the Miniature Bull Terrier Club of America

Miniature pinscher, *PIHN shuhr,* is a toy dog of the terrier family. It comes from the Rhine Valley of Germany. Germans sometimes call it a *reh pinscher* (deer terrier) because it looks like a small deer. It has a wedge-shaped head and black eyes. The dog may be red, black with rust-red markings, or brown with rust-red markings. It resembles the Doberman pinscher but weighs only 6 to 10 pounds (2.7 to 4.5 kilograms). See also **Dog** (picture: Toy dogs).

Critically reviewed by the Miniature Pinscher Club of America

Miniature schnauzer, *SHNOW zuhr,* is a breed of dog that originated in Germany in the 1800's. Breeders developed the dog by mating the standard schnauzer with the affenpinscher. The dog's high spirits and intelligence have helped make it popular in the United States. It is also a good watchdog and ratcatcher.

The dog's coloring may be salt and pepper, black and silver, black and tan, or all black. It has a shaggy beard and long, bushy eyebrows. Most owners have the dog's coat clipped short on top and the beard and eyebrows trimmed. The dog stands 12 to 14 inches (30 to 36 centimeters) tall at the shoulders and weighs about 15 pounds (7 kilograms).

Minimal art was a style of painting and sculpture that developed in the 1960's, particularly in the United States. Minimal artists removed recognizable images, the illusion of space, and narrative content from their works. Instead, they focused on the basic elements of art, such as line, shape, and color. Minimalism emphasizes geometric abstraction. Its influences were two art movements of the early 1900's, constructivism in Russia and De Stijl in the Netherlands. Minimalism was also influenced by the work of such American artists as Barnett Newman, Ad Reinhardt, and David Smith.

Most minimal works have an overall, unified composition, frequently incorporating a grid based on mathematical proportions. Most minimal paintings are of one color or contrast a limited number of colors. Brushstrokes are rarely visible. Many minimal works, especially sculptures, are made of everyday materials, including steel and other metals, fluorescent light tubes, house paint, or car paint. Many minimal sculptors design their work but do not take part in the actual creation. Instead, the sculpture is constructed industrially. Minimal works are generally large and rarely use frames.

A number of American painters and sculptors led the minimal movement. They included Carl Andre, Ronald Bladen, Dan Flavin, Donald Judd, Ellsworth Kelly, Sol LeWitt, Robert Mangold, Brice Marden, Agnes Martin, John McCracken, Robert Morris, Dorothea Rockburne, Robert Ryman, Richard Serra, Tony Smith, and Frank Stella. Deborah Leveton

Minimum wage is the smallest amount of money per hour that an employer may legally pay a worker. It may be established by law to cover all workers or only those in certain industries. Self-employed persons and employees of small businesses are often not covered by minimum wage laws.

In the United States, about 40 states have minimum wage laws or boards that set minimum wages. The first state law was passed in Massachusetts in 1912. Federal

minimum wage legislation became effective when the Fair Labor Standards Act was passed in 1938. The original act established a minimum wage of 25 cents per hour for 1938. The minimum wage has been increased a number of times by amendments to the Fair Labor Standards Act. The latest amendment, passed in 1996, called for raising the minimum wage from $4.25 an hour to $4.75 an hour in October 1996 and to $5.15 an hour in September 1997.

About 80 percent of all private industries are covered by the federal minimum wage. Most states set lower minimum wages than those set by federal legislation, and a few set them higher. In Canada, each province or territory sets its own minimum wage. There is also a minimum wage for employees of the federal government. In the United Kingdom, a national minimum wage went into effect in 1999. In some European countries, labor unions and employers establish unofficial minimum wages by agreement.

Minimum wage laws were set up to raise wages for low-income workers without substantially reducing their job opportunities. But today many economists feel employers do not hire as many low-income workers as they would if no minimum wage existed.

Paul L. Burgess

See also **Fair Labor Standards Act**.

Mining is the process of taking minerals or coal from the earth. Most substances that we get from the earth we obtain by mining. Mining provides iron for making airplanes, automobiles, and refrigerators. Mines also supply salt for food; gold, silver, and diamonds for jewelry; and coal for fuel. We mine stone for buildings, phosphate for fertilizer, and gravel for highways.

Some substances can be mined more cheaply than others because they are found at the earth's surface. Some lie far beneath the surface and can be removed only by digging deep underground. Other mined substances are found in oceans, lakes, and rivers.

Nicholas Devore III, Bruce Coleman Inc.

In an open-pit copper mine, miners use power shovels to load the mineral-bearing rock called *ore* onto trucks. The miners remove the ore in horizontal layers called *benches*. The trucks haul ore out of the mine to crushers.

People have mined the earth for thousands of years, perhaps first in Africa. Prehistoric people in Europe dug pits and tunnels to get flint, a hard stone used to make tools and weapons. Sometime after 3500 B.C., people were mining tin and copper. They combined these metals to make bronze, a hard *alloy* (mixture of metals) that made better tools and weapons. The ancient Romans probably were the first people to realize that mining could make a nation rich and powerful. Merchants traded valuable stones and metals and brought riches to the Roman Empire. The Romans took over the mines of every country they conquered.

The Roman Empire ended in the A.D. 400's. For about a thousand years, few advancements were made in mining. During the 1400's, coal, iron, and other materials were mined in Europe, especially in Germany, Sweden, and France. Mining also developed in South America. The Inca Indians and other peoples of South America used metals to make tools, jewelry, and weapons.

Mining began in what is now the United States during the early 1700's. French explorers mined lead and zinc in the valley of the Mississippi River. In the mid-1800's, miners began to dig up large amounts of coal in Pennsylvania. At about the same time, thousands of people rushed to California hoping to find gold. In the West, the gold rush led to the discovery of copper, lead, silver, and other useful minerals.

Most substances obtained by mining are minerals. A mineral is made of materials that were never alive. Thus, coal, petroleum, and natural gas are not considered true minerals because they were formed from the remains of plants that lived long ago. Coal, however, is obtained by mining. Because this article discusses the recovery of mined substances, it includes both minerals and coal. For information on drilling for oil and natural gas, see the *World Book* articles **Petroleum** and **Gas** (fuel).

Kinds of mining

There are many methods of mining. Each is based on where and how a coal or mineral deposit is found. Some deposits lie at or near the earth's surface, and others are far underground. Some minerals are found as a compact mass, and others are widely scattered. Minerals also vary in hardness and in the ease with which the mineral-bearing material called *ore* can be separated from the surrounding rocks. Some minerals occur in such large bodies of water as oceans and seas, and are obtained by pumping. For a discussion of the methods of mining a particular mineral, see the *World Book* article on that mineral. For details on coal-mining methods, see **Coal** (How coal is mined; illustrations).

Today, most mines are highly mechanized. Hydraulically powered drills bore holes in the ore. Large machines dig and load the ore, and trains, trucks, and conveyors transport it. In underground mines, high-speed elevators called *skips* carry ore to the surface.

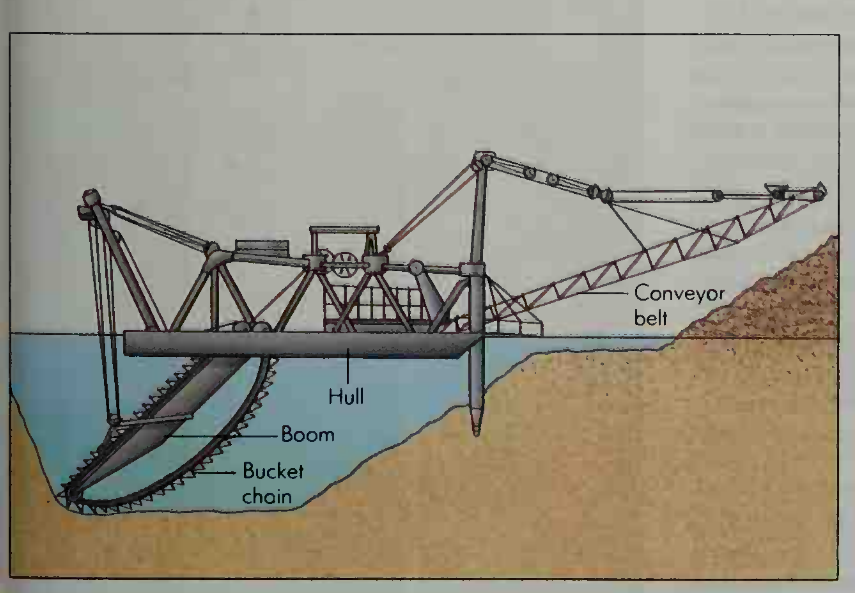
Surface mining methods are used when deposits occur at or near the surface of the earth. These methods include placer mining, dredging, open-pit mining, strip mining, and quarrying.

Placer mining is a way of obtaining gold, platinum, tin, and other so-called *heavy minerals* from gravel and

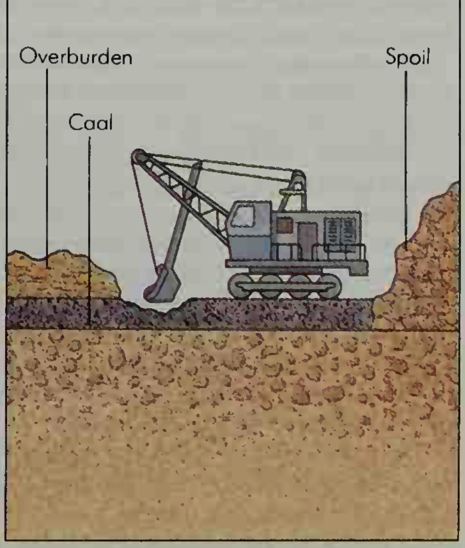
sand deposits where nearby water supplies are plentiful. The exact technique used depends on the size and kind of deposit. On a small scale, *panning* may be used to recover gold and other minerals from streams. On a larger scale, miners use a form of placer mining called *sluicing.* In this method, the mineral-bearing gravel and sand are shoveled into the upper end of a slanting wooden trough called a *riffle box.* In the box, they are washed by water. The valuable minerals are heavier than the sand and gravel, and settle in grooves on the bottom of the box. The gravel and sand are washed away. The mineral-bearing gravel and sand may also be moved directly from a deposit into the riffle box by the force of water shooting out through a large nozzle called a *giant.* This process is called *hydraulicking.*

Dredging is used especially where mineral-bearing sand and gravel layers are exceptionally thick. In dredging, a pond or lake must be formed so that a large, bargelike machine called a *dredge* can be floated. An endless chain of buckets is attached to a *boom* (long beam) at the front end of the dredge. The buckets dip into the water when one end of the boom is lowered. They dig up the mineral-bearing sand and gravel and move the material to a bin on the deck of the dredge. The material is taken from the bin and washed in much the same way as in placer mining. After the valuable minerals are collected, the sand and gravel are put on a conveyor belt and dumped back into the pond behind the dredge. By digging forward while disposing of the waste sand and gravel to the rear, the pond and the dredge move ahead as the deposit is mined.

When mining some kinds of loose gravel deposits, machines called *draglines* or *slacklines* are used. These machines have a scoop attached to a high boom. The scoop is pulled back and forth along the deposit to gather material, which is put into a separating bin.



Open-pit mining is used to recover valuable minerals from large, thick *orebodies* (beds or veins of ore) lying close to the surface. First, the miners must remove the *overburden*—that is, the layer of rock and other material that covers the deposit. Then they use explosives to break up great masses of ore-bearing hard rock. The miners mine the deposit in a series of horizontal layers called *benches.* Miners build a road connecting the benches up the sides of the pit. Trucks or trains haul the ore up the road and out of the pit.



Strip mining is a method of obtaining coal and such minerals as phosphate that lie flat near the earth's surface. Strip mining around hills or mountains is called *contour mining* or *collar mining.* Strip mining on flat terrain is called *furrow mining.* In this method, miners cut a furrow and cast the overburden into a ridge parallel to the cut called a *spoil.* They break the ore up with machines or explosives and then use shovels or machines to load the ore into trucks or railroad cars. After removing all the ore from the first cut, the miners cut a new furrow, casting the spoil into the previous cut.

In the past, strip mining had a bad reputation because it caused great destruction in the mined areas. This was especially true in mountainous areas, where strip mining would destroy vegetation on mountainsides and lead to mud slides and severe soil erosion.

Today, mining companies in the United States must plan for *reclamation* of the land before they can begin mining. Reclamation is a process in which the land is restored as closely as possible to its original state. In many cases, the reclaimed land is more valuable than it was before mining. For example, the lakes created in the final cuts of some mined areas have provided excellent fishing and water sports.

Quarrying is a way of mining a deposit that lies at the surface of the earth with little or no overburden. Such rocks and minerals as limestone, gypsum, and mica are produced from quarries. Sand and gravel used for making concrete and large stones used for building are also mined in quarries. Miners have several methods of quarrying. Hard minerals are drilled or are blasted with explosives. Sand and gravel are simply shoveled onto trucks or trains and shipped. Building stones such as marble and granite are sold in natural blocks or pieces. To free these blocks, miners saw, channel, or cut them on four sides, and wedge them free from parent rock.

WORLD BOOK illustrations by Oxford Illustrators Limited

Surface mining includes *dredging* and *furrow mining.* In dredging, *left,* buckets on a dredge scoop the ore from the bottom of a pond. In furrow mining, *right,* a power shovel uncovers coal and transfers the overburden to piles called *spoil.* The coal is broken up and loaded onto trucks.

Then the miners hoist the blocks onto trucks or trains.

Underground mining methods are used when the deposit lies deep beneath the earth's surface. First, the miners *drive* (dig) an opening into the mine. A vertical opening is called a *shaft*. A passage that is nearly horizontal, dug into the side of a hill or mountain, is called an *adit*. In coal mining, it is called a *slope*. From these main passages, miners dig systems of horizontal passages called *levels*. A wide variety of mining methods are available for removing the ore. Types of underground mining include (1) room-and-pillar mining, (2) longwall mining, (3) sublevel stoping, (4) cut-and-fill mining, (5) block caving, and (6) sublevel caving.

Room-and-pillar mining is a method of recovering ore from horizontal or nearly horizontal orebodies. Miners excavate the orebody as completely as possible, leaving parts of the ore as pillars to support the *hanging wall* (the rock above the ore vein). Room-and-pillar mining is the most widely used method of underground mining in the United States. Materials commonly mined using this method include coal and the minerals lead, limestone, potash, salt, and uranium.

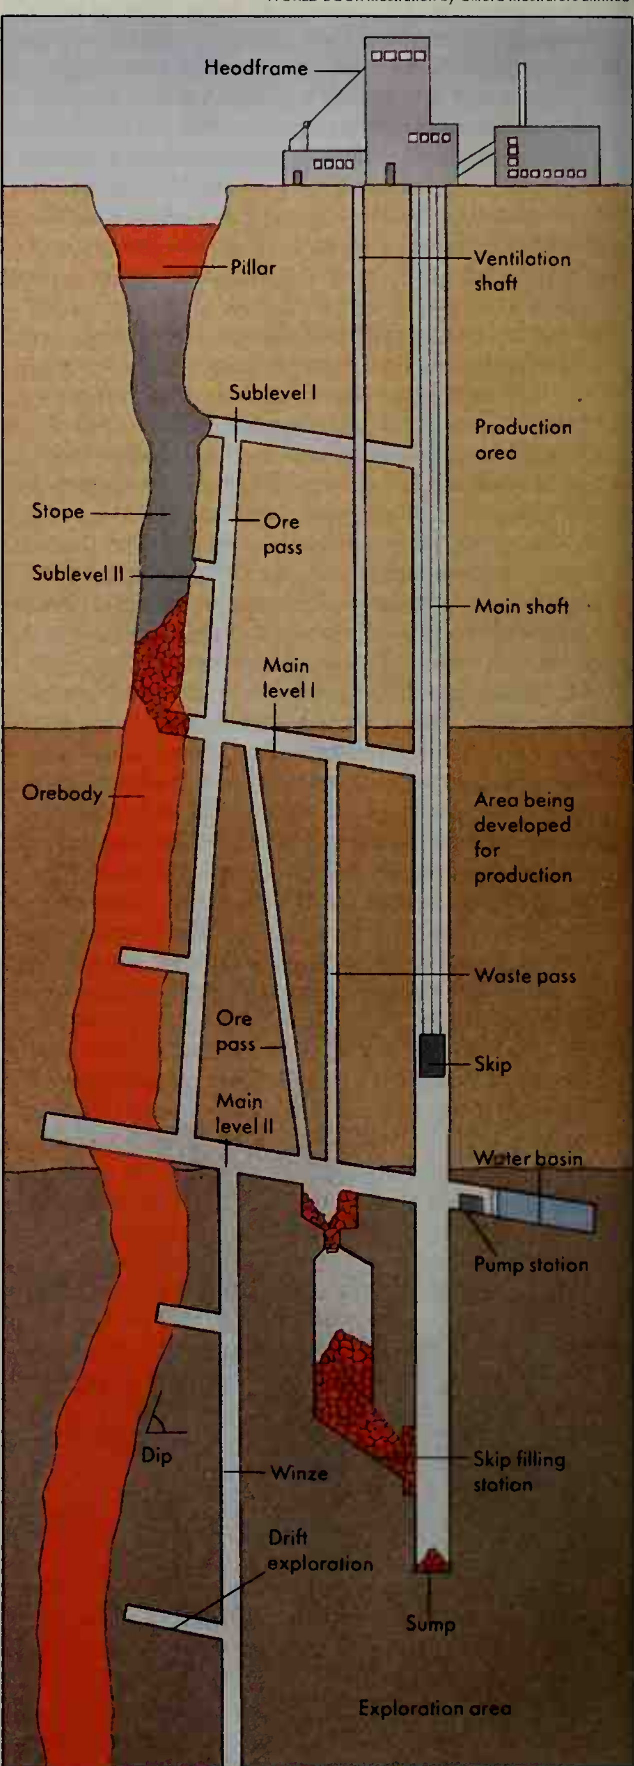
Longwall mining is also used to dig ore from horizontal seams. Miners use a machine to cut or break ore from a single long face called a *longwall*. Hydraulic roof supports hold up the hanging wall above the miners. As the miners dig farther into the vein, the supports advance with them, and the hanging wall behind them collapses.

Sublevel stoping is used in orebodies with a steep *dip*. A dip is the angle the orebody makes with the horizontal. Miners develop sublevels between the main levels and drill and blast the ore from both the sublevels and main levels. As the ore is removed, empty chambers called *stopes* form. The ore, broken in large vertical slices, falls to the bottom of the empty stopes. There, it is recovered for transport out of the mine.

Cut-and-fill mining is a method of removing ore from vertical veins in horizontal slices, starting at the stope's bottom and advancing upwards. After miners excavate a slice of ore, they fill the stope with waste material called *gangue* or waste sand from ore-processing plants. This material supports the walls and provides a working platform from which to mine the next ore slice.

Block caving is a way of mining such ores as copper and iron when they are scattered throughout the waste material. In this method, the miners dig levels, dividing the orebody into large sections or blocks. Then they undercut each block with a horizontal slot. The pressure of the overlying rock and ore causes the ore above the slot to cave in. Large machines transport the ore to vertical or inclined openings called *ore passes*.

Sublevel caving is used in large, steeply dipping orebodies. Miners divide the orebody into sublevels 25 to 50 feet (7.5 to 15 meters) apart. Each sublevel is developed with a network of *drifts* (horizontal passages) that penetrate the complete ore section.



From the sublevel drifts, the miners drill deep holes into a fan-shaped pattern in the ore section immediately above. The blasting of one fan breaks the ore, causing it to cave into the drift. There, it is loaded and transported to the ore passes.

Pumping methods are used to recover minerals that occur in large bodies of water or that can be changed

A shaft mine

A shaft mine is a system of horizontal and vertical passages through which ore is removed and hauled to the surface. Gold, lead, and other minerals in vertical veins are mined in this way.

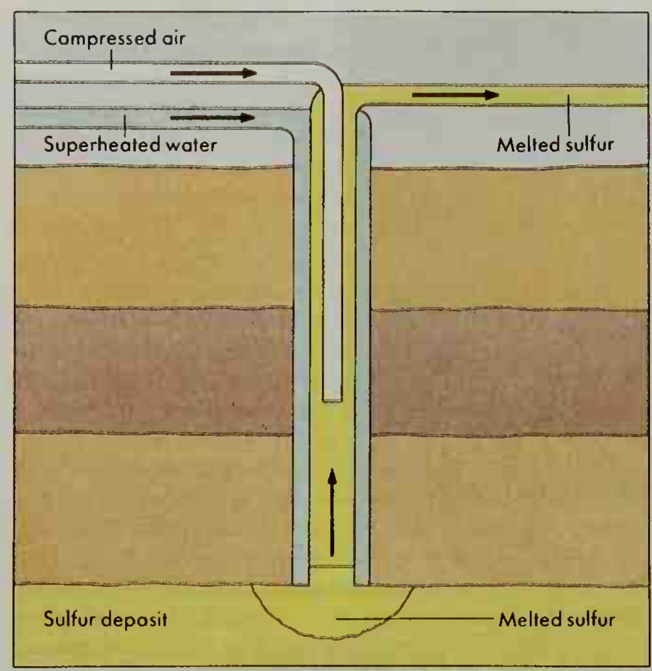
A continuous miner digs coal or ore from horizontal seams deep underground. In a single operation, the machine gouges out the mineral with its rotating cutter and loads it onto a shuttle car.

into liquid form. The waters of the ocean and of some lakes, including Great Salt Lake in Utah, contain huge amounts of mineral elements. Miners often obtain these minerals by pumping the water into plants where it is treated. Pumps move large amounts of seawater through *precipitators* (separators) in order to remove the minerals. Most of the magnesium used today is obtained by this method.

Pumping is sometimes used to get salt from beds beneath the surface of the earth. Mine workers drill holes and circulate water underground to dissolve the salt and form a saltwater solution called *brine.* The brine is then pumped to the surface and taken to a factory. There, the water is evaporated, and the salt forms a solid again.

The Frasch process, another pumping method, is often used in mining sulfur, a mineral that melts easily. The miners bore holes in a buried sulfur bed and inject superheated water. The sulfur then melts and forms a liquid. The miners force the liquid sulfur to the surface by pumping compressed air into the holes. After the sulfur cools, it becomes a solid again and can be stored until needed.

The mining industry



In the late 1990's, the annual value of U.S. mining production was about $55 billion. In Canada, the value of mineral production in U.S. dollars was about $14 billion a year. These figures do not include oil and natural gas production because they are not obtained by traditional mining methods. But economists often include oil and natural gas in mining statistics.

The United States mining industry employs about 535,000 people and offers a wide variety of careers for professional, skilled, and semiskilled workers. Management in the mining industry consists mainly of business people and engineers. These people manage mines, smelters, and refineries, and direct the search for new deposits. They also try to improve mining methods.

Many universities and colleges offer training for specialized careers in mining industry engineering. A *geological engineer* or *geologist* guides the search for

Mining terms

Adit is a nearly horizontal passage from the earth's surface into a mine.
Crosscut is a horizontal or nearly horizontal mine passage that intersects the orebody.
Dip is the angle an ore deposit is inclined from the horizontal.
Drawpoint is a place where ore can be loaded and removed.
Drift is any underground mine passage.
Footwall is the wall or zone of rock under an inclined vein. It is beneath the miners' feet as they excavate the ore.
Gangue is the worthless material mixed with the ore.
Hanging wall is the wall or zone of rock above an inclined vein. It hangs above the miners as they excavate the ore.
Level is the group of drifts and crosscuts made at one depth in an underground mine. Miners usually develop several levels.
Ore pass is a vertical or inclined underground opening through which ore is dropped.
Outcrop is the exposed surface of a deposit.
Overburden is the soil or rock that covers a deposit.
Pillar is a thick post of rock created by removing the surrounding rock.
Quarry is an open or surface excavation from which building stone is usually obtained.
Raise is a passage driven upward from a lower level toward an upper level in an underground mine.
Ramp is an inclined underground opening. It connects levels or production areas and allows the passage of motorized vehicles.
Shaft is a vertical passage from earth's surface into a mine. It is shaped like an elevator shaft.
Skip is a bucket, cage, or wagon in which materials or miners are drawn up or let down a mine shaft.
Stope is an underground excavation formed by the removal of ore between one level and the next in a mine.
Strike is the main horizontal direction of a deposit.
Stripping is the process of removing the overburden.
Sublevel is a system of horizontal underground workings.
Sump is the bottom of a mine shaft where water, sludge, or rocks may collect.
Tunnel is a horizontal underground passage that opens to the surface at both ends.
Vein is a deposit with definite boundaries that separate it from the surrounding rock.
Waste pass is a vertical or inclined opening through which waste material is dumped.
Water basin is a collection area for water that has seeped into a mine or has been piped into the mine and used in drilling. Pumps push this water to the surface.
Winze is a passage that has been driven downward from one level toward a lower level in an underground mine.

WORLD BOOK illustration by Oxford Illustrators Limited

The Frasch method of mining sulfur involves pumping hot water into the deposit through a pipe to melt the sulfur. Compressed air flows into the deposit through a second pipe and forces the sulfur to rise to the surface through a third pipe.

mineral deposits and estimates their value. A *mining engineer* designs the mine and directs the mining process. A *metallurgist* or *metallurgical engineer* directs *beneficiation* (milling, smelting, and refining) of minerals so the company can sell or use them. The mining industry also employs computer specialists, surveyors, and scientists, including chemists and physicists.

Among the workers in mines are people skilled in operating and maintaining various kinds of mining machinery. Other workers include mechanics, electricians, truckdrivers, and laborers. Some people with mining experience are federal or state mine inspectors. They help enforce laws that promote miners' health and safety. Others with mining experience may be involved in the sale of mining equipment, materials, and supplies.

For more on mining careers, contact the American Institute of Mining, Metallurgical and Petroleum Engineers, based in New York City. William Hustrulid

Leading mining states and provinces

Value of annual mining production

State/Province	Value
West Virginia	$4,187,000,000
Ontario	$3,840,000,000
Kentucky	$3,611,000,000
California	$3,270,000,000
Pennsylvania	$3,028,000,000

Figures are in U.S. dollars for 2000 and do not include petroleum or natural gas production.
Sources: *World Book* estimates based on data from U.S. Geological Survey, U.S. Energy Information Administration, and Statistics Canada.

Minister, in international relations, is a diplomatic agent who represents his or her country in a foreign land. Ministers are appointed by the head of their country, and they rank below ambassadors.

In the United States, the president appoints ministers. Ministers, like all other diplomatic agents of the United States, get their credentials from the U.S. secretary of state. In some countries, the name *minister* is also given to high administrative officers who make up the cabinet or executive body (see **Cabinet**). Robert J. Pranger

See also **Ambassador; Diplomacy; Ministry.**

Minister, in religion, is one who serves. Especially in Protestantism, a minister is an ordained member of the clergy who usually acts as pastor of a congregation. In addition to conducting worship services, an ordained minister usually administers the sacraments, preaches, and assumes responsibility for the pastoral care of the congregation. Lay ministers, who are not ordained, may assist at worship services. For example, they often read parts of the liturgy and lessons and help distribute Communion. In Roman Catholic, Eastern Orthodox, and Anglican churches, priests fill the role of ordained ministers. Ralph W. Quere

Ministry, in government, is a body of executive officers who advise the head of a country or directly control a country's affairs. In many cases, these officials are parliament members and heads of executive departments.

Ministries are part of the governmental setup of countries that have a parliamentary form of government. The ministry of the United Kingdom has furnished the model for all nations using the parliamentary system.

The British ministry consists of the prime minister and a number of other officers known as the *ministers.* The monarch appoints the prime minister, usually selecting the leader of the party in control of the House of Commons. The monarch's selections of the other ministers are based on the recommendations of the prime minister. British ministers are members of Parliament and are divided into *Cabinet ministers* and *ministers not in the Cabinet.* Cabinet ministers vary from Cabinet to Cabinet. Major bills are introduced by ministers.

The British ministry represents the political party or

parties that control the House of Commons. When it can no longer get parliamentary support, the ministry resigns. Robert G. Neumann

Mink is a small mammal prized for its fur. The luxurious winter pelts of minks have long been in demand by the fur industry, which uses them to make expensive capes, coats, stoles, and other clothing.

Minks have slender bodies and short legs. They weigh from about $1\frac{1}{2}$ to $2\frac{3}{4}$ pounds (0.7 to 1.2 kilograms). They range in length from about 20 to 25 inches (50 to 64 centimeters), not including their bushy tails. Wild minks have brown fur. But minks raised in captivity have been bred to have black, blue, silver-gray, and white coats.

There are two species of minks, the North American mink and the European mink. The North American mink lives throughout most of North America. It is slightly larger than the European mink, which originally lived in northern Europe and northern and central Asia. Only the fur of American minks has commercial value.

How minks live. Minks live in rural and wilderness areas near rivers, streams, marshes, and lakes. They hunt in the water and on land. Their underwater prey include crayfish, frogs, and minnows. Minks, however, have limited underwater vision. Therefore, they often sight their prey from the shore and then dive into the water and try to catch it. The double-layered fur of minks helps them hunt in water. The oily outer layer repels water, keeping the mink dry. The soft, thick layer beneath keeps the mink warm. On land, minks hunt under logs, between rocks, and in rodent burrows for mice, muskrats, rabbits, and snakes. Their enemies include bobcats, foxes, and certain types of owls.

Female minks have litters of from 2 to 10 young. They give birth in the spring. The mothers raise and feed the young without help from the males. By the end of their first summer, the young can feed themselves. By the end of their first year, they have established their hunting territories and they can reproduce. Minks rarely live beyond three years.

© Tom Brakefield, Bruce Coleman Inc.

Wild minks live in North America, northern Europe, and northern and central Asia. They inhabit rural and wilderness areas near rivers, streams, marshes, and lakes.

© Ray F. Hillstrom

White minks are specially bred on *mink ranches,* also called *mink farms.* Minks raised in captivity have also been bred to have black, blue, and silver-gray fur.

Minks are legally trapped in winter throughout their range in North America. The pelts of female minks, though smaller than those of males, often are more valuable, because they are less coarse.

Mink ranches. American minks are raised in captivity on *mink ranches,* also called *mink farms,* in many parts of the world. The fur of minks raised on ranches is less likely to be damaged than the fur of wild minks. Many American minks have escaped from ranches in northern Europe. These minks have established wild American mink populations that have nearly caused the extinction of the native European mink.

Scientific classification. Minks belong to the weasel family, Mustelidae. The North American mink is *Mustela vison.* The European mink is *M. lutreola.* Roger A. Powell

See also **Fur.**

Minke, *MIHNG kee,* **whale** is a relatively small whale that lives in all oceans from the polar regions to the tropics. Female minke whales reach a maximum length of about 33 feet (10 meters) and males are slightly smaller. A minke whale has a slender body that is black or dark gray on top and lighter below. It has a high, sharply curved *dorsal fin* on the rear part of the back. Minke whales that live north of the equator typically have a wide white band on their flippers.

Some minke whales migrate, especially those found in and near polar areas. Other minkes have been observed year around in certain coastal areas. In waters near Antarctica, minke whales feed mainly on tiny shellfish called *krill.* In other areas, minke whales mainly eat whatever fish are abundant.

Hundreds of thousands of minke whales live in the world's oceans. Most nations have banned the hunting of all types of whales to protect them from extinction. However, Japan, Norway, and several other countries permit limited minke whale hunting.

Scientific classification. The minke whale belongs to the family Balaenopteridae in the suborder Mysticeti, order Cetacea. Its scientific name is *Balaenoptera acutorostrata.*

WORLD BOOK photo by Richard Sennott

Minneapolis is the largest city in Minnesota and an important Midwestern economic center. Downtown Minneapolis has many modern buildings. The Minnesota Twins baseball team and the Minnesota Vikings football team play home games at the Hubert H. Humphrey Metrodome, *right.*

Minneapolis, *MIHN ee AP uh lihs,* is the largest city in Minnesota and a major Midwestern center of finance, industry, trade, and transportation. The city also is the home of the University of Minnesota, one of the nation's largest universities. Minneapolis lies in southeastern Minnesota, just west of St. Paul, its "twin city."

The name *Minneapolis* comes from the Indian word *minne,* meaning *water,* and the Greek word *polis,* which means *city.* Minneapolis got its name because of the 22 natural lakes that lie within the city limits. It has the nickname *City of Lakes.*

In the late 1840's, farmers and lumberjacks settled the area that is now Minneapolis. They chose the area because of its broad farmlands and hardwood forests. In addition, the nearby Falls of St. Anthony, on the Mississippi River, supplied water power for their flour mills and sawmills. In 1849, a village called Saint Anthony was established on the east side of the falls. In 1852, settlers on the west side of the falls chose the name Minneapolis for their growing community. Saint Anthony became a city in 1855, and Minneapolis did so in 1867. In 1872, the two cities merged under the name Minneapolis.

From 1882 to 1930, Minneapolis led the world in flour production. After World War II ended in 1945, the city became an important producer of computers, electronic equipment, and farm machinery. Today, service industries, especially education, finance, and retail trade, are the most important economic activities.

Facts in brief

Population: *City*—382,618. *Metropolitan area*—2,968,806.
Area: 59 mi² (153 km²). *Metropolitan area*—6,065 mi² (15,708 km²), excluding inland water.
Climate: *Average temperature*—January, 14 °F (−10 °C); July, 74 °F (23 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—32 inches (81 centimeters). For the monthly weather in Minneapolis, see **Minnesota** (Climate).
Government: Mayor-council. *Terms*—4 years for the mayor and the 13 council members.
Founded: 1849. Incorporated as a city in 1867.

Metropolitan Minneapolis

The city covers 59 square miles (153 square kilometers), including 4 square miles (10 square kilometers) of inland water. The Mississippi River divides Minneapolis into two areas, the larger of which is west of the river. Most of the huge University of Minnesota campus lies on the east bank, but part of the campus is on the west bank.

Downtown Minneapolis, on the west bank, faces the Falls of St. Anthony. Nicollet Avenue, the chief shopping street, features an eight-block-long shopping center called Nicollet Mall. The law permits cabs and buses—but not automobiles—to drive on the mall. The Investors Diversified Services (IDS) Center faces Nicollet Mall. It includes the 57-story IDS Tower, the tallest building in Minnesota. The IDS Tower and many buildings near it are connected by the Skyway System. The system consists of enclosed elevated passageways between the buildings. Heated in winter and air-conditioned in summer, the Skyway System provides comfort for people moving about in the area. The city's main financial district is on Marquette Avenue, a block southeast of Nicollet Avenue.

The metropolitan area covers about 6,065 square miles (15,708 square kilometers), excluding inland water, and spreads over 11 counties in Minnesota and 2 in Wisconsin. Communities in this area include St. Paul, Minnesota's capital and second largest city, and Bloomington, Minnesota's fifth largest city. The Minnesota part of the metropolitan area has nearly 3 million people—about 60 percent of the state's population. The Minneapolis and St. Paul business districts are connected by the Interstate 94 expressway.

The people

About two-thirds of Minneapolis's people are of European origin. Major population groups include people of German, Norwegian, Swedish, or English descent. African Americans make up about 18 percent of the city's population. Hispanic Americans, who may be of any race, account for nearly 8 percent. Asians, a fast-growing segment of the population, make up about 6 percent of the city's people. About 2 percent of the people are American Indians. Minneapolis has one of the largest American Indian populations of any U.S. city.

Economy

Commerce and industry. Service industries employ about one-third of all Minneapolis workers. Wholesale and retail trade employ about one-fourth, and one-fifth

WORLD BOOK maps

City of Minneapolis

Minneapolis is an industrial city on the Mississippi River. The large map shows the city's major landmarks. The small map shows Minneapolis and its twin city, St. Paul.

The Nicollet Mall, a landscaped downtown shopping area, occupies eight blocks along Nicollet Avenue.

of the city's population have jobs in manufacturing. Several major wholesale and retail firms have their headquarters in the city. Minneapolis is a major financial center. It is the headquarters of the Ninth Federal Reserve Bank District, which serves a six-state region.

Minneapolis ranks as a major center for commercial printing and flour milling. Other important economic activities include the production of computer equipment and industrial machinery.

Transportation. Airlines use the Minneapolis-St. Paul International Airport. Six railroad freight lines serve the city, and passenger trains use a terminal in St. Paul. Twenty bridges in Minneapolis cross the Mississippi River. Several major highways, including two interstate routes, pass through the city. The Minneapolis-St. Paul area ranks among the top trucking terminals in the United States. More than 150 trucking companies serve the area.

Communication. Minneapolis has one daily newspaper, the *Star Tribune*. Eight television stations and about 35 radio stations broadcast in the Minneapolis-St. Paul area.

Education

The Minneapolis public school system includes about 50 elementary and high schools with a total of about 40,000 students. Blacks make up about 32 percent of the enrollment. Asians make up 10 percent of the enrollment, and Indians account for 8 percent. The city has a busing program to achieve racial balance in the public schools. About 8,000 students attend 32 parochial and private schools in Minneapolis.

The Twin Cities campus of the University of Minnesota has facilities in Minneapolis and St. Paul. It ranks as one of the nation's largest university campuses. Other institutions of higher learning in Minneapolis include Augsburg College, North Central University, the Minneapolis College of Art Design, and St. Thomas University.

The Minneapolis Public Library has 16 branches and owns more than a million books. Libraries of the University of Minnesota contain about 3 $\frac{1}{2}$ million volumes.

Cultural life

The arts. The Minnesota Orchestra has its headquarters at Orchestra Hall near Nicollet Mall. The Guthrie Theater is the home of one of the best-known theater groups in the United States. In addition, Minneapolis is known for its numerous small theater companies and dance groups.

Museums. The Walker Art Center owns one of the country's finest collections of modern art. The Minneapolis Institute of Arts displays masterpieces dating from 2000 B.C. to modern times. The Planetarium of the Minneapolis Public Library features sky shows.

Recreation

Minneapolis has been called the *Vacation Capital* because it serves as the gateway to northern Minnesota's lake region. The Minneapolis Aquatennial, which is held every July, features a canoe derby, costume balls, parades, and water ballets. The annual Minnesota State Fair takes place in early fall at the State Fairgrounds in St. Paul. The highlights of the fair include carnival shows and agricultural and industrial exhibits. The Mall of America, a major retail and recreation center in Bloomington, has about 400 stores and an indoor amusement park.

Parks. Minneapolis has about 150 public parks, which cover about 6,000 acres (2,400 hectares). Most of the parks line the shores of the Mississippi River or surround the many small lakes within the city. Theodore Wirth Park, the largest park in Minneapolis, covers almost 740 acres (300 hectares) and has a wooded area for hiking.

Minnehaha Park includes Minnehaha Falls, which is 53 feet (16 meters) high. The American poet Henry Wadsworth Longfellow made Minnehaha Falls famous in his long poem *The Song of Hiawatha*. See **Minnehaha Falls**.

Summer vacationers enjoy boating and swimming at Lake Minnetonka, which is 12 miles (19 kilometers) long and lies 12 miles southwest of Minneapolis. Many of the city's tourists visit Fort Snelling, the center of the first permanent white settlement in what is now the Minneapolis area.

Sports. A number of professional sports teams play in Minneapolis. These teams include the Minnesota Twins baseball team of the American League, the Minnesota Vikings of the National Football League, and the Minnesota Timberwolves of the National Basketball Association.

Government

Minneapolis has a mayor-council form of government. The voters elect the mayor and 13 council members to four-year terms. Property taxes, state aid, and municipal fees provide the city's most important sources of revenue.

In 1967, Minnesota established the Metropolitan Council of the Twin Cities Area. This governmental

agency has the power to tax and to sell bonds. It deals with such areawide concerns as health, housing, land use, sewer construction, transportation, waste disposal, and water pollution. It consists of 14 members and a chairperson, all appointed by the Minnesota governor.

History

Early days. Sioux Indians once farmed and hunted in what is now the Minneapolis area. In 1680, a Belgian explorer and missionary named Louis Hennepin became the first white person to visit the site. In 1819, the U.S. Army established Fort St. Anthony in a temporary building there. From 1820 to 1822, American soldiers serving under Colonel Josiah Snelling built Fort St. Anthony as a permanent fort. The fort was renamed Fort Snelling in 1825. Fort Snelling served for more than 30 years as a trading center and a gateway to the northern wilderness and the western prairies.

Industrial development. During the 1840's, the great forests of the area attracted lumberjacks from Maine. The lumberjacks built sawmills near the Falls of St. Anthony. In 1849, the village of St. Anthony was established on the east side of the falls. Another community developed on the west side of the falls. In 1852, the settlers chose the name Minneapolis for the village on the west side. St. Anthony became a city in 1855. Minneapolis was incorporated as a city in 1867. In 1872, the two cities merged under the name Minneapolis.

In 1854, grain millers built a large flour mill in Minneapolis to take advantage of the area's rich wheat fields. Flour milling soon became a major industry of Minneapolis. By 1870, Minneapolis ranked as the state's principal lumbering center.

In the 1870's, a flour-sifting device called the *purifier* was perfected in Minneapolis. It enabled millers to produce high-quality flour from inexpensive spring wheat. Large flour mills helped the city grow. By 1880, Minneapolis had 46,887 people.

In 1882, Minneapolis became the world's leading flour-milling center. Both Minneapolis and St. Paul developed into important transportation centers about this time. But Minneapolis grew faster than St. Paul because it had greater industrial development. By 1890, Minneapolis had a population of 164,738.

The increased use of steam-powered machinery during the late 1800's led to rapid growth of the city's lumber industry. From 1899 to 1905, Minneapolis led the world in lumber production. But by 1906, most of the nearby forests had been cut down, and the city's lumber trade declined sharply. The population of Minneapolis grew from 202,718 in 1900 to 301,408 in 1910.

By 1916, General Mills, Incorporated, The Pillsbury Company, and other local firms produced such huge quantities of flour that Minneapolis became known as *Mill City.* But a large increase in freight rates during the 1920's caused the grain companies to establish milling centers in other parts of the country. In 1930, Buffalo, New York, replaced Minneapolis as the world's leading center of flour production. That year, Minneapolis had 464,356 people.

Following World War II, Minneapolis became a leader in the manufacture of computers, electronic equipment, and farm machinery. By 1950, the downtown area had become old and shabby. People and industry began moving from the city to the suburbs during the 1950's. The population fell from 521,718 in 1950 to 482,872 in 1960. During the 1970's and 1980's, the city's population continued to fall. However, the population of the metropolitan area increased.

Downtown redevelopment. Since the 1950's, private investors have spent large sums of money to redevelop the downtown area. Gateway Center, a renewal project begun in 1958, was largely completed in the mid-1970's. It features apartment and office buildings and covers 18 blocks in the heart of the city. The Nicollet Mall was completed in 1968 and the IDS Center in 1972.

In the late 1980's, the Nicollet Mall underwent a major renovation, and several new department stores opened, boosting a declining retail trade. The entertainment district along Hennepin Avenue was revitalized as well.

Recent developments. Voters elected Sharon Sayles Belton mayor in 1993. Sayles Belton became the city's first African American mayor and first female mayor. She held office until 2002.

By 2000, Minneapolis had 382,618 people. The population of the city had grown by about 4 percent during the 1990's. Belvel J. Boyd

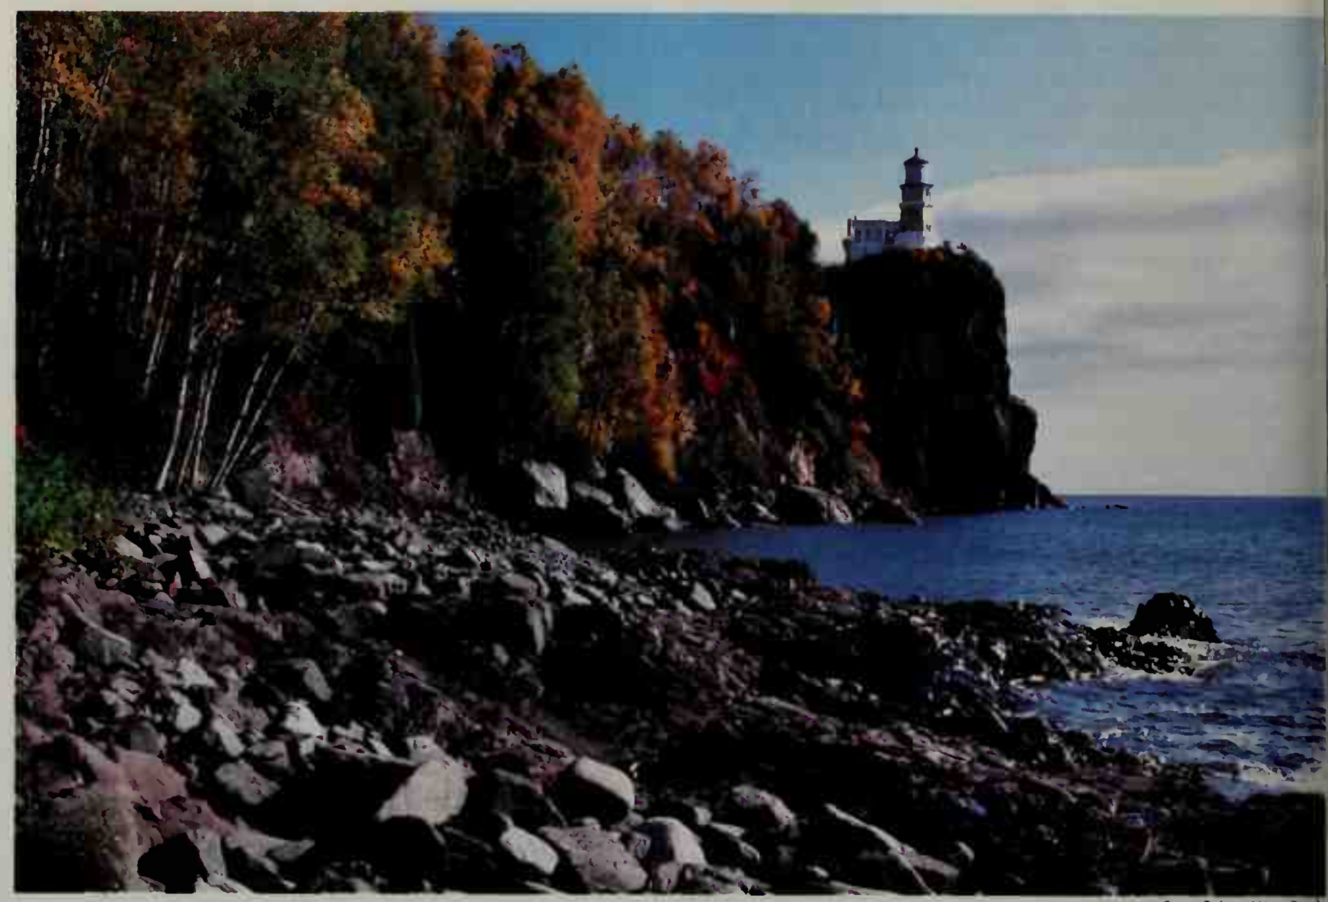
Minnehaha Falls, *MIHN ee HAH hah,* is a waterfall on Minnehaha Creek in Minneapolis, Minnesota. *Minnehaha* means *laughing waters* in the Sioux Indian language. The falls are 53 feet (16 meters) high. Over thousands of years, they have cut a deep gorge in the surrounding sandstone and limestone cliffs. Minnehaha Falls is part of a city park and appears on the city seal. Over 500,000 people visit the park each year. The American poet Henry Wadsworth Longfellow made the falls famous in *The Song of Hiawatha* (1855), a poem based on Indian legend. A statue of the Indian leader Hiawatha and his wife stands at the top of the waterfall. Gordon L. Levine

See also Minnesota (picture).



Minnesinger, *MIHN uh SIHNG uhr,* was one of a group of German love poets who flourished from the late 1100's to the late 1300's. The minnesingers sang their poetry to music at court festivals.

Minne was an old German word meaning *love.* The minnesingers' expressions of love were regulated by the courtly society that placed much value on form. Courtly love, as many minnesingers portrayed it, was a knight's hopeless love for a lady of high station. The knight's plea for the lady's love was often expressed in feudal terms such as a vassal might use in begging a favor from his lord. The lady usually remained unapproachable.

The doctrines and forms of courtly love developed in southern France and spread to Germany. In addition to ideas of the feudal system, several literary traditions influenced the minnesingers. These included Arabic poetry transmitted from Spain, classical literature such as Ovid's *The Art of Love,* and medieval Latin poetry. The homage paid to the Virgin Mary in the 1100's also contributed to the idealization of women so basic to much of courtly love poetry.

The leading minnesingers included Dietmar von Aist, Kürenberger, Heinrich von Veldeke, Friedrich von Hausen, Heinrich von Morungen, Reinmar von Hagenau, Walther von der Vogelweide, Neidhart von Reuenthal, Tannhäuser, and Ulrich von Lichtenstein. James F. Poag

The Minnesota shoreline stretches along Lake Superior in the northeast part of the state. Rugged cliffs and thick forests provide beautiful wilderness scenery in this region, making it one of Minnesota's most popular vacation areas.

Minnesota *The Gopher State*

Minnesota is a large state in the Midwestern United States. The state is an important producer of agricultural and manufactured goods. Such service industries as finance and trade are also important to its economy. Minnesota's Twin Cities of Minneapolis and St. Paul form a major metropolitan area of the Midwest. St. Paul is Minnesota's capital, and Minneapolis is the state's largest city.

Southern Minnesota has some of the nation's richest farmland. Thousands of dairy cattle in this area make Minnesota one of the leading milk-producing states. Minnesota is also a major producer of corn, hogs, soybeans, and wheat.

The processing of farm products is a leading manufacturing activity in Minnesota. Large dairy plants, flour mills, and meat-packing plants are found in several parts of the state. Minnesota's other chief manufacturing activity is the production of computers. The Twin Cities and Rochester have large computer companies.

Minneapolis is a leading financial center of the Midwest. Retail trade employs many people in the Twin Cities. Duluth has the busiest freshwater port in North America. The Mayo Clinic in Rochester is a world-famous medical center.

Minnesota's scenic beauty, sparkling lakes, and deep pine woods make it a vacation wonderland. Its plentiful game animals and fish attract people who enjoy hunting and fishing. Campers, canoeists, and hikers can explore its vast northern wilderness areas.

The state's history is much the story of the development of its great natural resources. The fur-bearing animals of Minnesota's forests first attracted fur traders. Next, the fertile soil brought farmers, who poured into the region from the Eastern States and from Europe. The thick forests of tall pines attracted lumberjacks from Maine, Michigan, and Wisconsin. Finally, miners came to dig the state's vast deposits of rich iron ore.

The name *Minnesota* comes from two Sioux Indian words meaning *sky-tinted waters.* During the late 1800's, the state's flour mills and dairy products gave Minnesota one of its nicknames—the *Bread and Butter State.* But it is best known as the *Gopher State.* This nickname can be traced to an 1857 cartoon that represented dishonest railroad organizers as striped gophers. Gophers, known for being destructive to farm crops, live mainly in the state's southern and western prairies.

The contributors of this article are William E. Lass, Professor of History at Mankato State University; and Gordon L. Levine, Director of the Alworth Institute for International Studies at the University of Minnesota, Duluth.

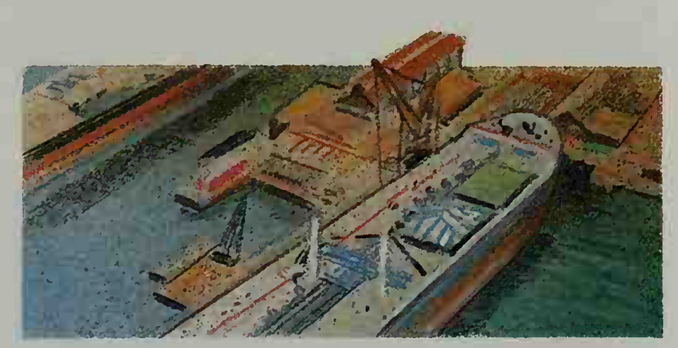
The Crystal Court Mall of the IDS Center in Minneapolis attracts many visitors. Minneapolis is the largest city in Minnesota.

Interesting facts about Minnesota

WORLD BOOK illustrations by Kevin Chadwick

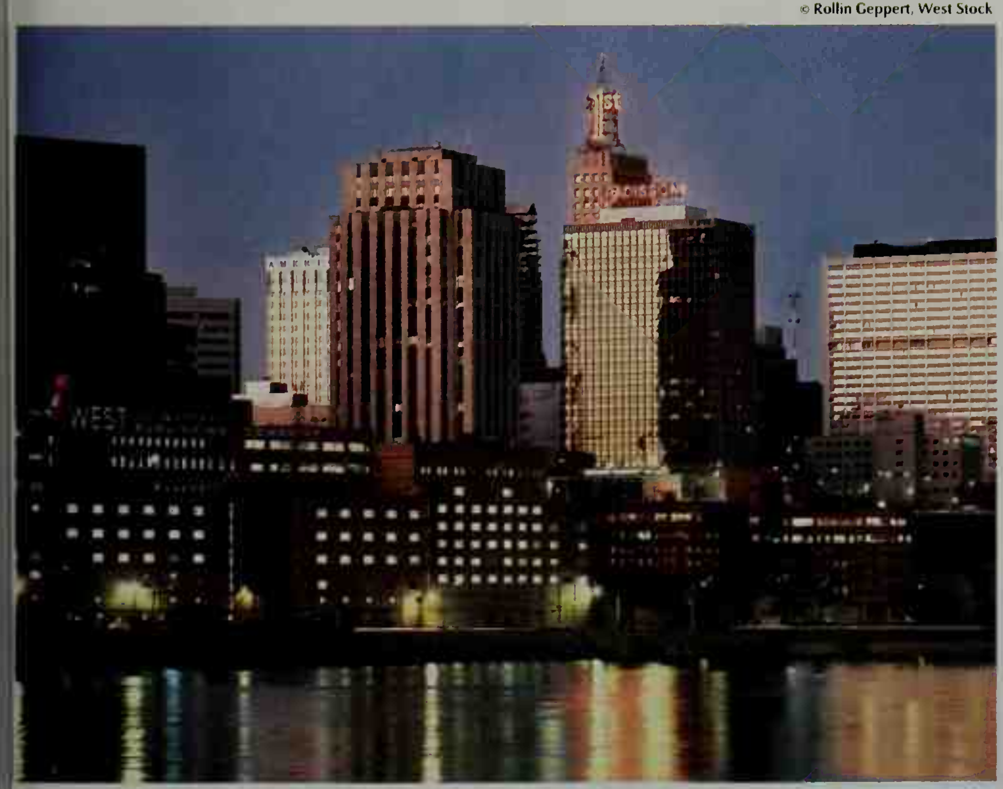
General James Shields was the only person ever elected United States senator by three different states. A Democrat, he served during the middle and late 1800's as senator of Illinois, Minnesota, and Missouri.



General James Shields

The first national farm organization was founded by Oliver H. Kelley of Minnesota. It was called the National Grange, Patrons of Husbandry.

The home thermostat was invented and first manufactured in Minneapolis in 1885, by Alfred M. Butz.



Cellophane transparent tape was invented and patented by Richard Gurley Drew of St. Paul. The Minnesota Manufacturing and Mining Company began producing the tape in 1930.

The busiest freshwater port in North America is the port of Duluth, Minn.-Superior, Wis. The port is also the farthest inland ocean port in the United States.

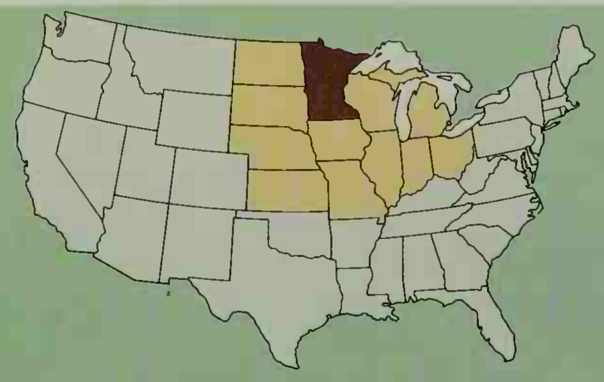
Port of Duluth

© Rollin Geppert, West Stock

The city of St. Paul lies chiefly along the north bank of the Mississippi River. About half of Minnesota's people live in the Minneapolis-St. Paul metropolitan area.

Minnesota in brief

Symbols of Minnesota

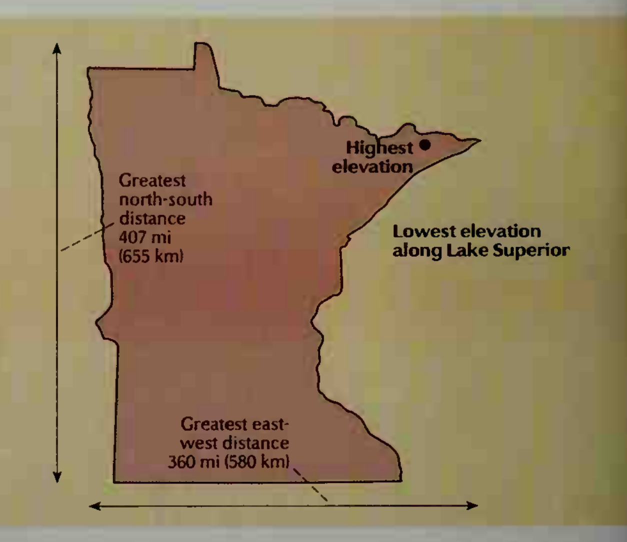


The state flag, adopted in 1983, bears a version of the state seal. The dates *1819, 1858,* and *1893* indicate, respectively, the year of Minnesota's first settlement, the year of statehood, and the year the original flag was adopted. The seal was adopted in 1861. A man plowing symbolizes agriculture and a stump stands for the lumber industry, both important parts of the state's history. An Indian represents Minnesota's Indian heritage.

State flag

State seal

Minnesota (brown) ranks 12th in size among all the states and is the largest of the Midwestern States (yellow).



The State Capitol is in St. Paul, the capital of Minnesota since it became a territory in 1849.

General information

Statehood: May 11, 1858, the 32nd state.
State abbreviations: Minn. (traditional); MN (postal).
State motto: *L'Etoile du Nord* (The Star of the North).
State song: "Hail! Minnesota." Words by Truman E. Rickard and Arthur E. Upson; music by Truman E. Rickard.

Land and climate

Area: 84,397 mi^2 (218,587 km^2), including 4,780 mi^2 (12,381 km^2) of inland water but excluding 2,546 mi^2 (6,594 km^2) of Great Lakes water.
Elevation: *Highest*—Eagle Mountain, 2,301 ft (701 m) above sea level. *Lowest*—602 ft (183 m) above sea level along Lake Superior.
Record high temperature: 114 °F (46 °C) at Moorhead on July 6, 1936, and at Beardsley on July 29, 1917.
Record low temperature: −60 °F (−51 °C) at Tower on Feb. 2, 1996.
Average July temperature: 70 °F (21 °C).
Average January temperature: 8 °F (−13 °C).
Average yearly precipitation: 26 in (66 cm).

Important dates

1679 Daniel Greysolon, Sieur Duluth, explored Lake Superior's western shore.

1783 Britain granted the land east of the Mississippi River to the United States.

1803 The United States obtained the Minnesota area west of the Mississippi through the Louisiana Purchase.

1820-1825 The U.S. Army built Fort St. Anthony, which was renamed Fort Snelling in 1825.

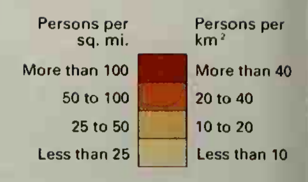
1955 A large taconite-processing plant began operations at Silver Bay.
1982 Minnesota adopted a state constitutional amendment establishing a Court of Appeals.

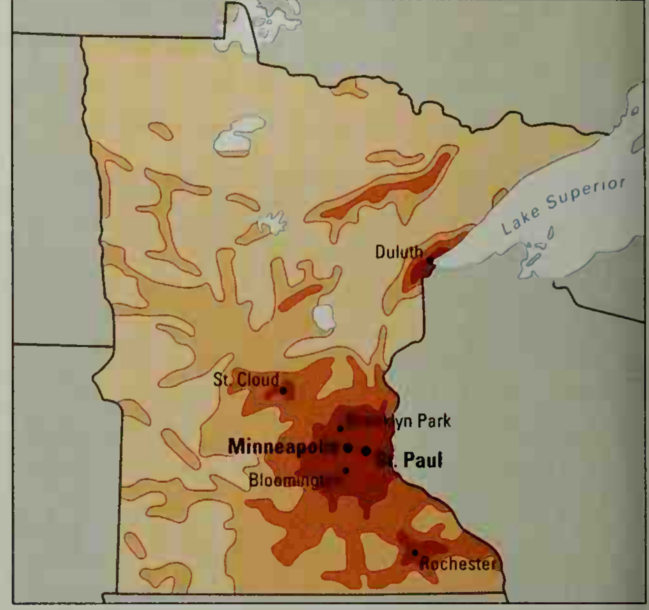
People

Population. The 2000 United States census reported that Minnesota had 4,919,479 people. The population of the state had increased 12 $\frac{1}{2}$ percent over the 1990 census figure, which was 4,375,099. According to the 2000 census, Minnesota ranks 21st in population among the 50 states.

About 70 percent of Minnesota's people live in metropolitan areas (see **Metropolitan area**). More than half of the people live in the Minneapolis-St. Paul Metropolitan Statistical Area. For the names and populations of the state's metropolitan areas, see the *Index* to the political map of Minnesota.

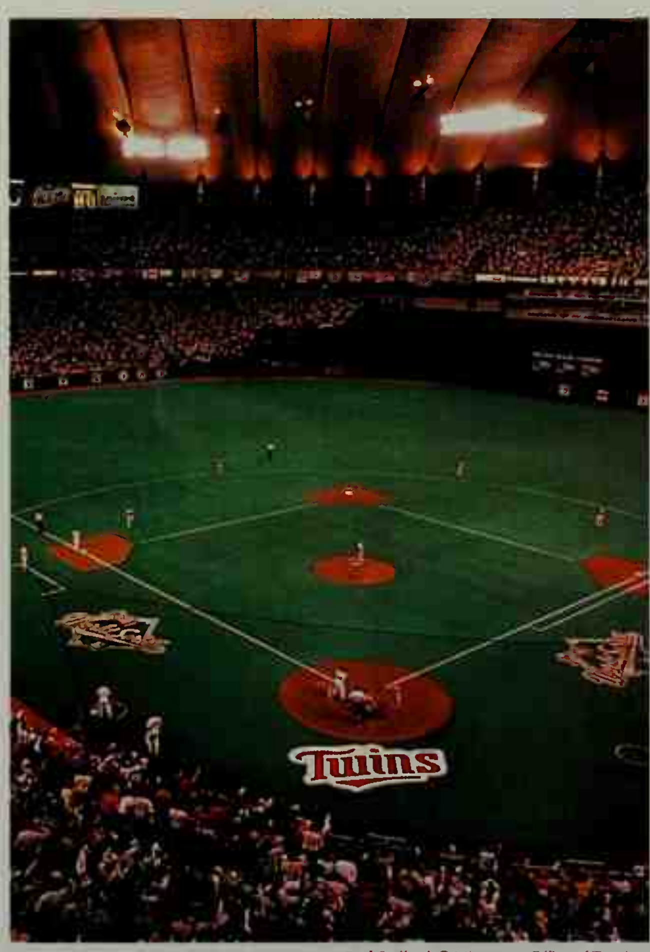


Minneapolis is the largest city in Minnesota. It adjoins St. Paul, Minnesota's capital and second largest city. The Twin Cities, as they are called, serve as the state's leading cultural, financial, and commercial center. The state's next largest cities, in order of population, are Duluth, Rochester, Bloomington, Brooklyn Park, and Plymouth.



African Americans, Asians, and Hispanics each account for about 3 percent of Minnesota's population. The largest groups of people who settled in Minnesota during the 1800's and early 1900's came from Finland, Germany, Norway, and Sweden. Many also came from Austria, Canada, Denmark, the United Kingdom, Ireland, Poland, and Russia.

Schools. About 1820, the first school for white children was opened at Fort St. Anthony (later renamed Fort Snelling). Missionaries set up some Indian schools dur-



Population density

Most of Minnesota's residents live in the southeast. More than half the people live in the Minneapolis-St. Paul metropolitan area. The north and west are thinly populated.

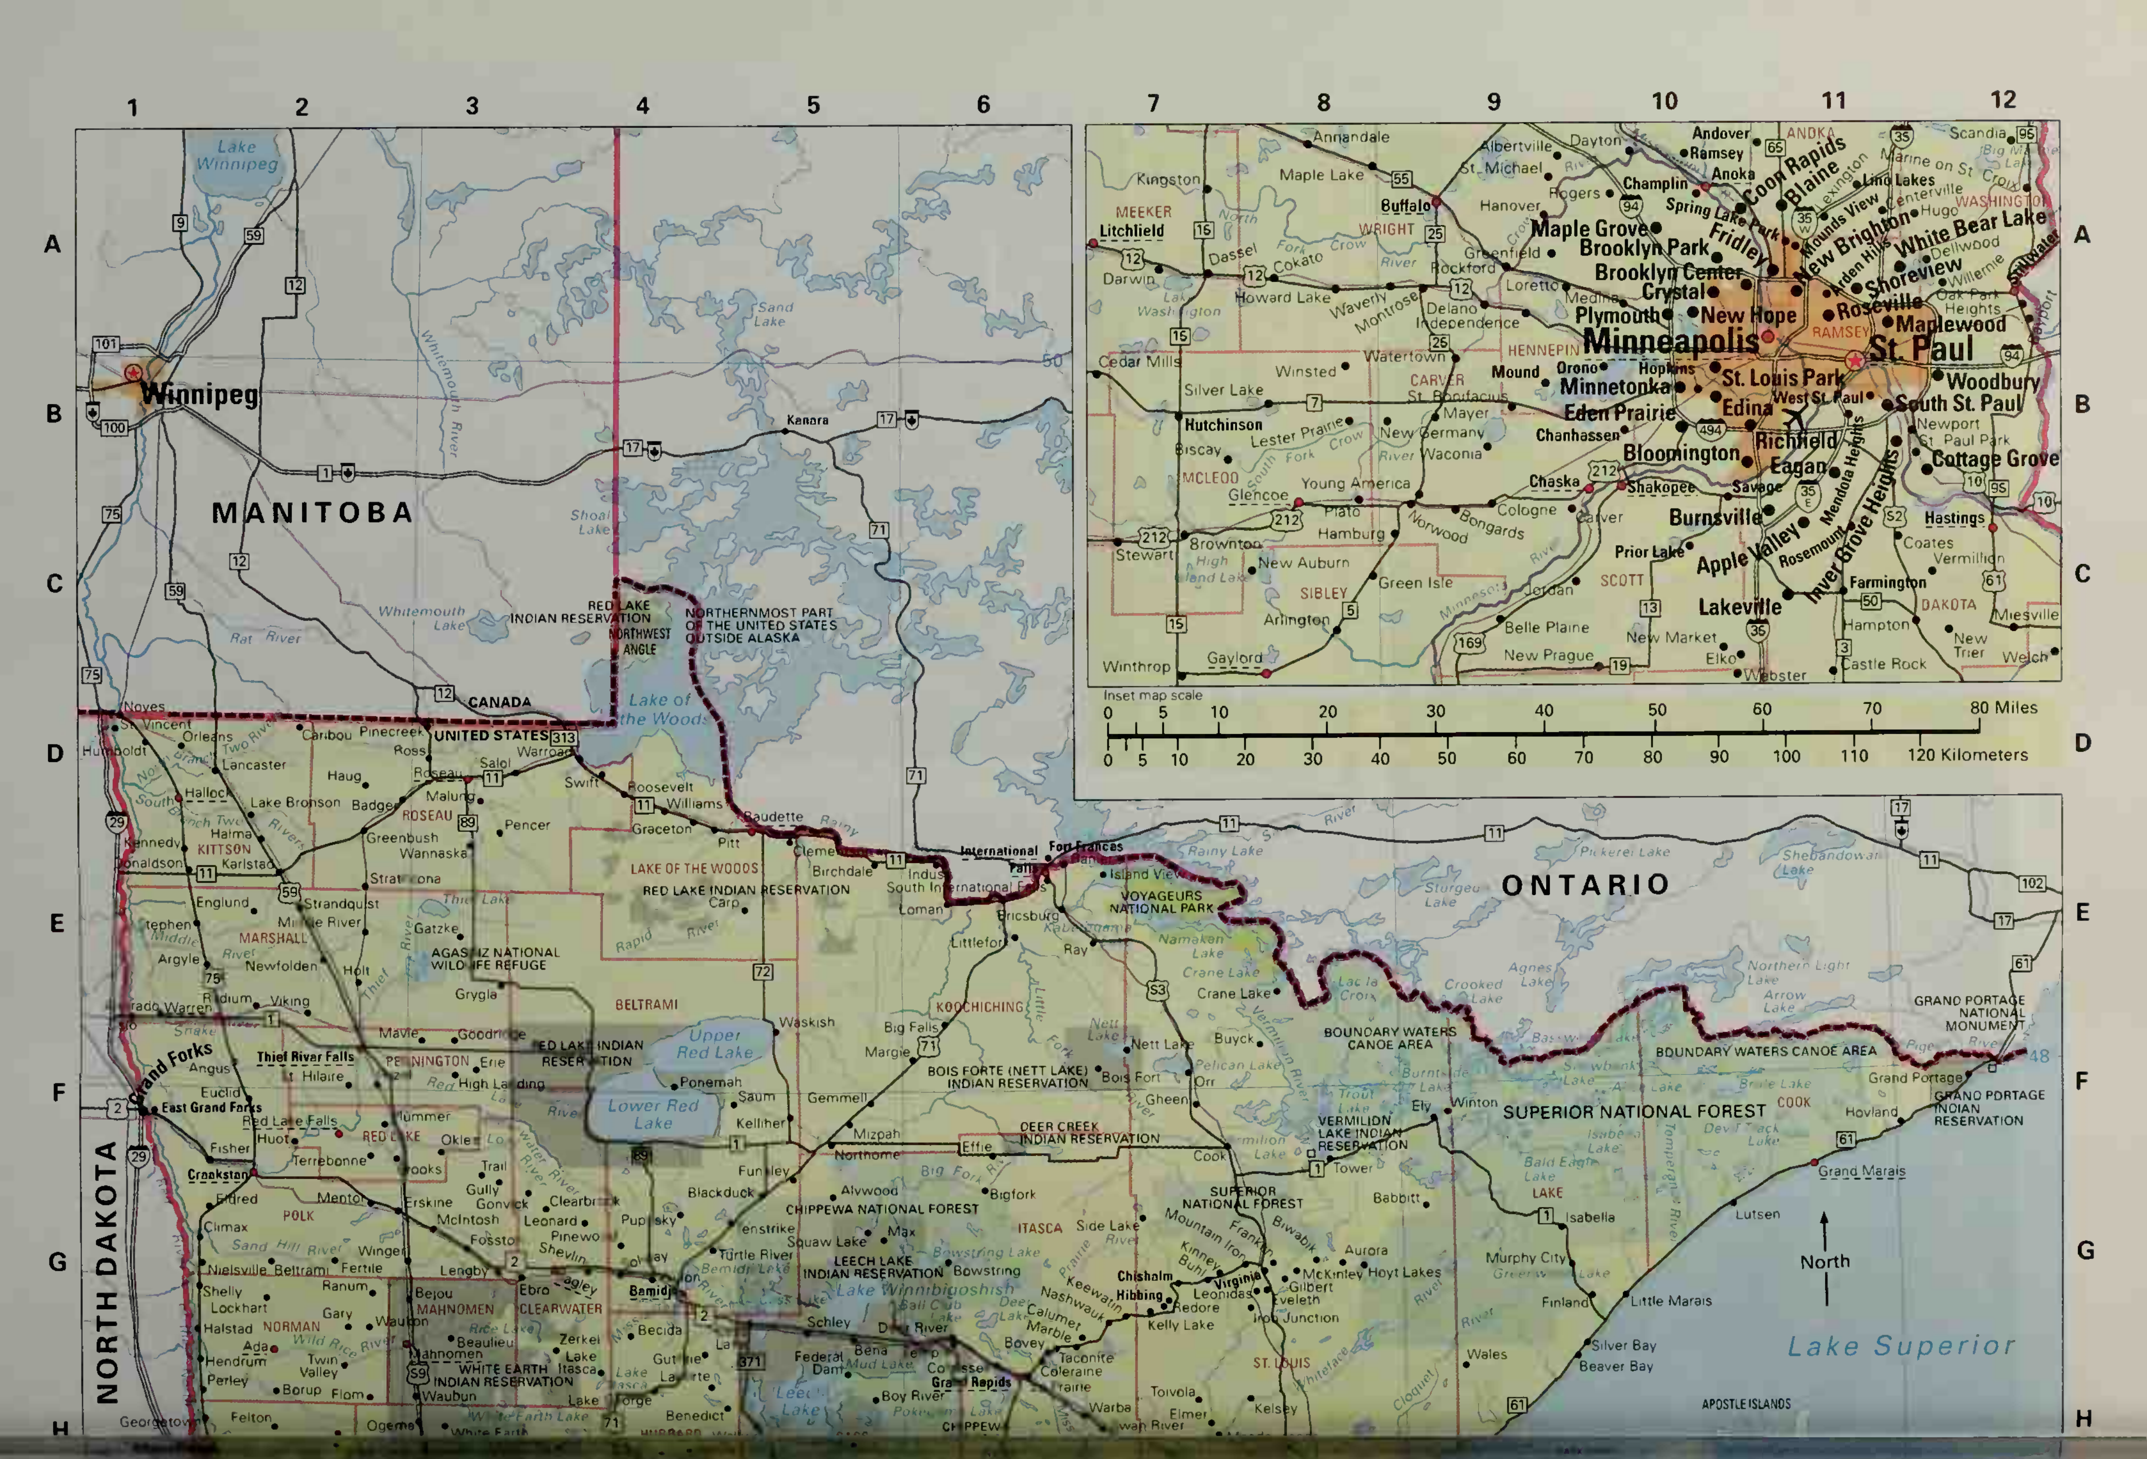
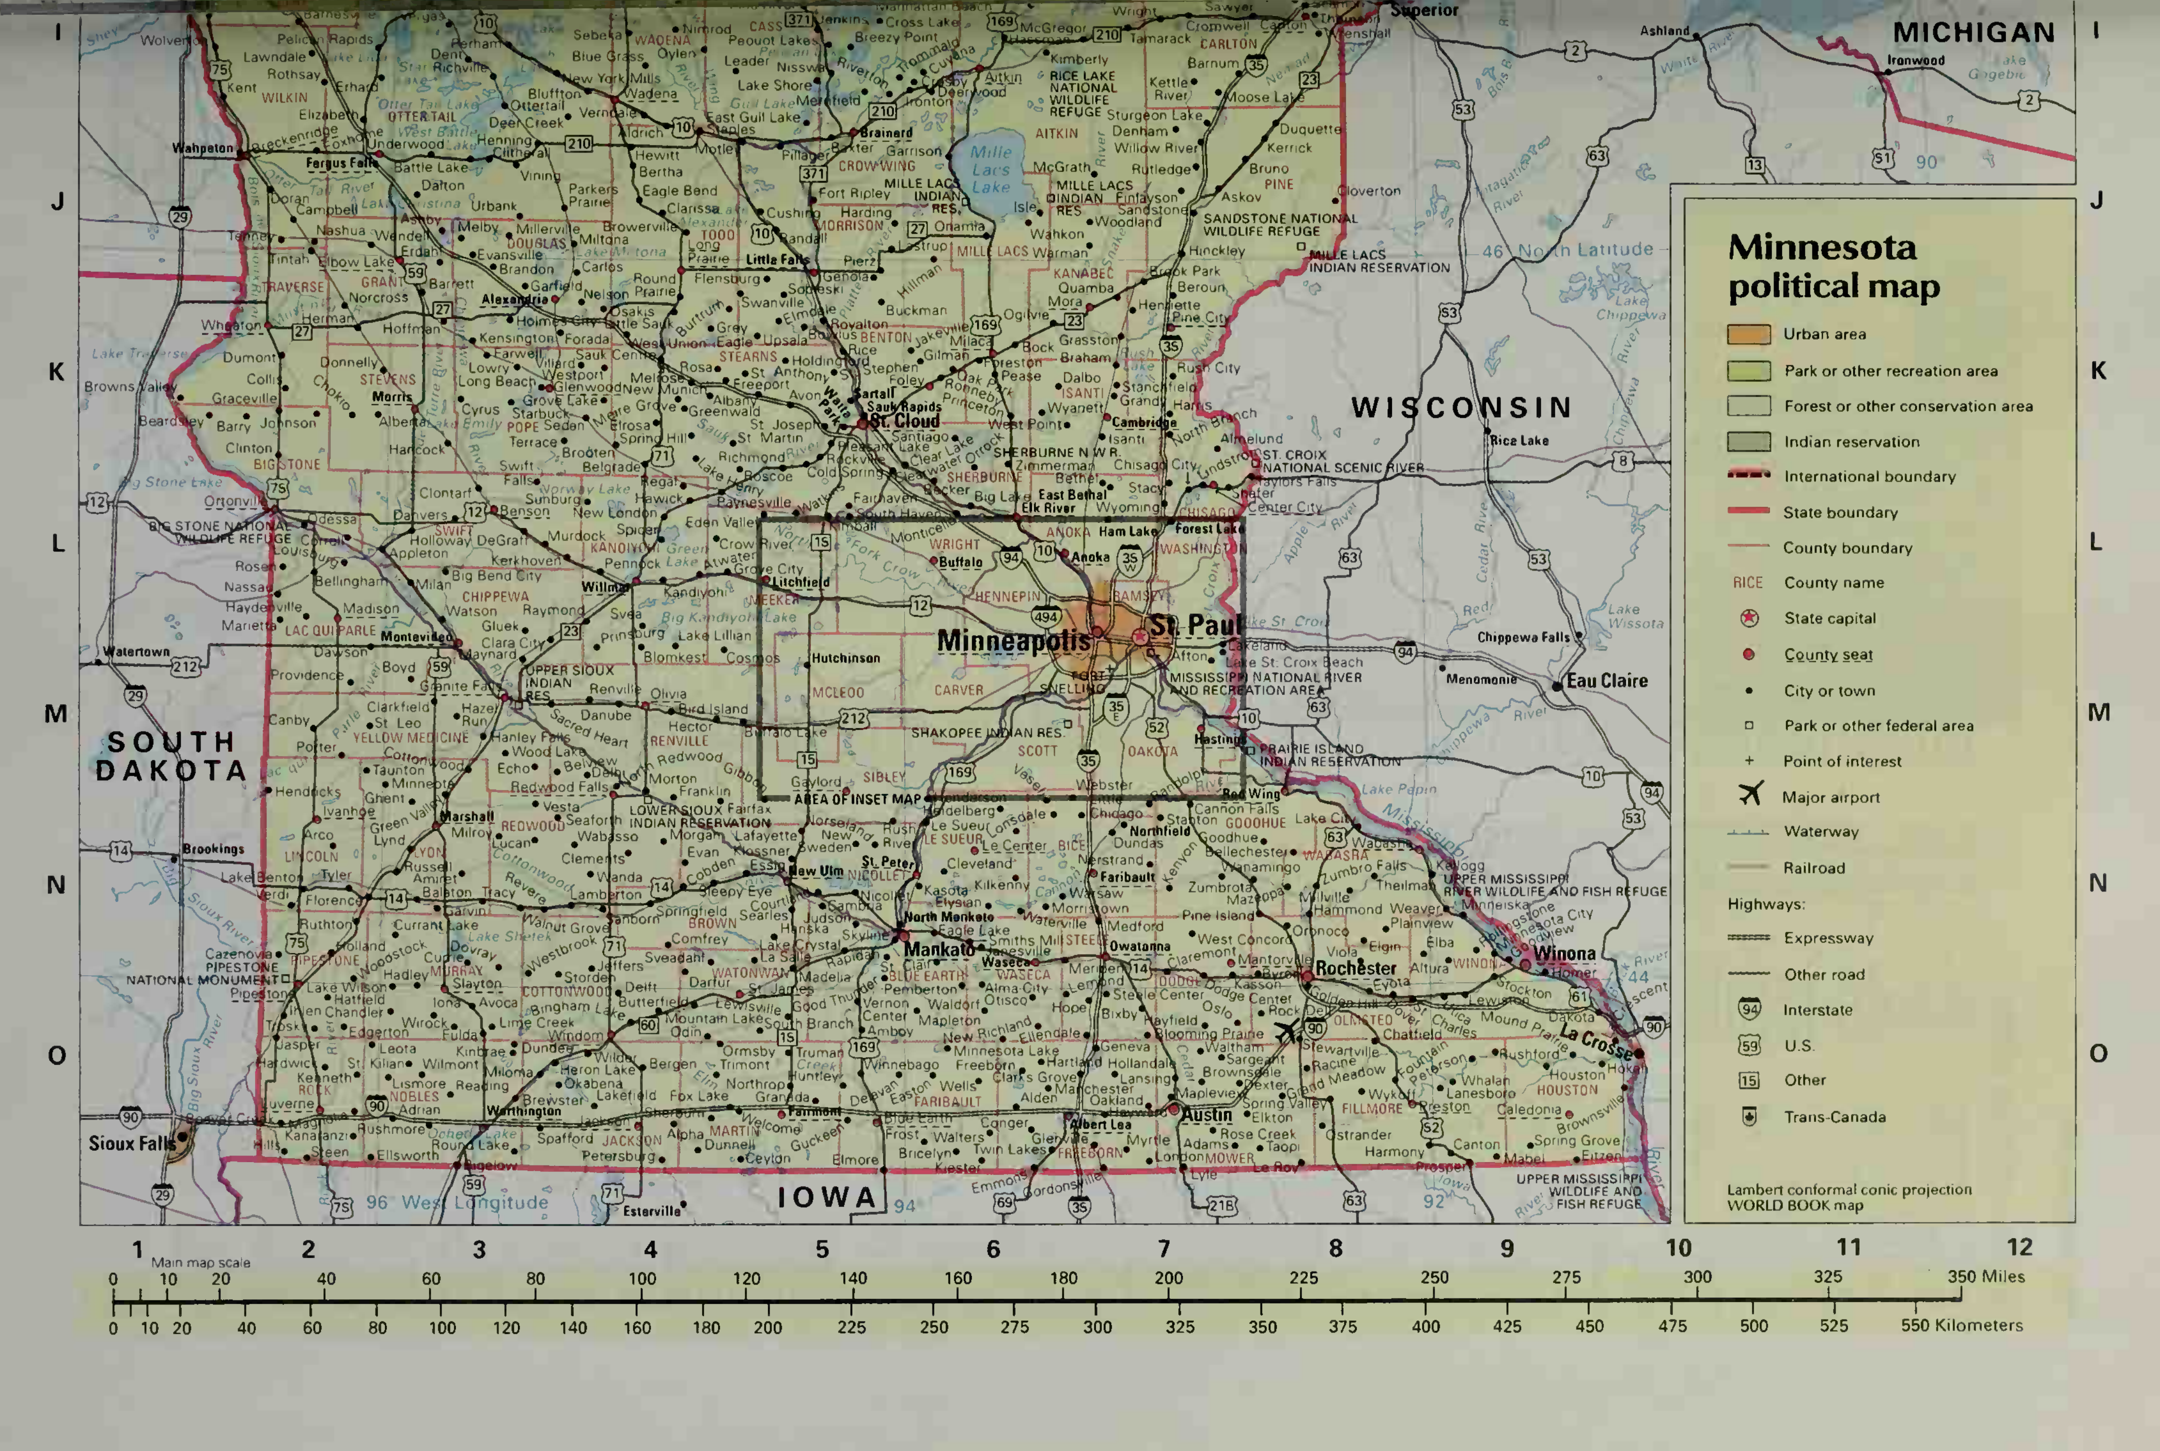
ing the 1830's. In 1849, the territorial legislature passed a law providing for the establishment of public schools in Minnesota.

The Minnesota Department of Children, Families, and Learning oversees and supports school districts throughout the state. Its chief administrator, the commissioner, is appointed by the governor to a four-year term with approval of the state Senate.



Minnesota offers open enrollment across school districts. The state requires children to attend school between their 7th and 18th birthdays. The nation's first charter schools opened in Minnesota in 1991. For the number of students and teachers in the state, see **Education** (table).

Libraries. Minnesota has about 360 public libraries. The largest ones serve Minneapolis, St. Paul, and Hennepin County. The libraries of the Twin Cities Campus of the University of Minnesota have the largest collection in the state. The university has some of the country's largest collections of materials dealing with children's literature, European expansion, and Scandinavia.



Other important library collections in Minnesota include the James J. Hill Reference Library, the Minnesota Historical Society Library, and the State Law Library, all in St. Paul; and the Mayo Medical Library in Rochester. Statewide library networks allow Minnesotans to have access to materials from the state's largest public and university libraries.

Museums. The Minneapolis Institute of Arts is the largest art museum in Minnesota. Its artworks come from many periods and cultures. The Walker Art Center, also in Minneapolis, has an outstanding collection of modern art.

The Science Museum of Minnesota in St. Paul has exhibits dealing with science, technology, and natural history. The Lake Superior Railroad Museum in Duluth features railroad cars and equipment. The Canal Park Marine Museum in Duluth traces the history of commercial shipping in the upper Great Lakes region.

Visitor's guide

Minnesota is one of the nation's most popular playgrounds. Every year, several million residents and out-of-state visitors spend their vacations in Minnesota. Thousands of sparkling blue lakes attract swimmers, water skiers, and boaters. Fishing enthusiasts find the cool northern waters filled with a great variety of game fish. Wooded parks and deep forests are scattered throughout the state. Skiing, snowmobiling, and ice fishing are favorite winter activities.

Minnesota's long, cold winters are ideal for winter carnivals and sports festivals. The St. Paul Winter Carnival begins the last week in January. The carnival features ice-skating races, and ski-jumping and ice sculpture contests.

The Minneapolis Aquatennial, held in July, features boat races, costume balls, and a torchlight parade. Minnesota holds its State Fair in St. Paul from late August through Labor Day.

Places to visit

Forest History Center, in Grand Rapids, includes a reconstructed logging camp of the 1800's. Exhibits trace human life in Minnesota from prehistoric times to the present.

Fort Snelling is a restored military post near St. Paul. It was established in temporary buildings in 1819 and built as a permanent fort between 1820 and 1825. The fort features demonstrations dealing with life of the 1820's.

Glensheen is a lavish 39-room mansion in Duluth. It was built in 1905 by Chester A. Congdon, a wealthy mining executive.

Great Lakes Aquarium, in Duluth, is the only all-freshwater aquarium in the United States. Exhibits focus on the history and wildlife of Lake Superior.

Ironworld, near Chisholm, features exhibits on the history of mining in Minnesota. It has an outdoor amphitheater, park, and a train that tours two open-pit mines.

Mall of America, in Bloomington, includes about 400 stores, a number of movie theaters and nightclubs, and an indoor amusement park with a roller coaster.

Minnesota Zoo, in Apple Valley, exhibits about 250 species of animals in natural settings.

Science Museum of Minnesota, in St. Paul, features science, technology, and natural history exhibits. Its omnitheater shows films on a domed screen that surrounds the audience.

Statues of Paul Bunyan and Babe, in Bemidji, honor the legendary lumberman and his giant blue ox. Brainerd also has a huge statue of Paul.

The Guthrie Theater, in Minneapolis, presents some of the nation's finest dramatic performances.

National parklands in Minnesota include two national monuments—Grand Portage and Pipestone. Grand Portage National Monument, on the northwestern shore of Lake Superior, marks the site of a historic canoe route and trading post. For centuries, Indian peace pipes have been made from the red pipestone found at Pipestone National Monument. Voyageurs National Park, near International Falls, has scenic waterways. For information on other national parklands in the state, see the article on National Park System.

National forests. Minnesota has two national forests. Superior National Forest lies in the northeast and includes the Boundary Waters Canoe Area, the nation's only wilderness preserved for canoeists. Chippewa National Forest covers much of Itasca County and parts of Beltrami and Cass counties.

State parks and forests. Minnesota has about 65 state parks and about 45 state forests. For information on the state parks, write to Parks and Recreation Division, Department of Natural Resources, 500 Lafayette Road, St. Paul, MN 55155-4001.

Annual events

January-March
Ice Box Days winter festival in International Falls (January); St. Paul Winter Carnival (late January-early February); International Eelpout Festival in Walker (February); John Beargrease Sled Dog Race between Duluth and Grand Marais (February); Vasaloppet Ski Race in Mora (February); Voyageur Winter Festival in Ely (February).

April-June
Festival of Nations in St. Paul (April or May); Swayed Pines Folk Fest in Collegeville (April); Maple Syrup Festival in Annandale (April); Cinco de Mayo in St. Paul (May); Mayflower Festival in Duluth (May); Grandma's Marathon in Duluth (June); Rochesterfest in Rochester (June); Wheels, Wings & Water Festival in St. Cloud (June).

July-September
Heritagefest in New Ulm (July); Taste of Minnesota food festival in St. Paul (July); Minneapolis Aquatennial (July); Automobile racing at the Brainerd International Raceway in Brainerd (July-August); Fishermen's Picnic in Grand Marais (August); Renaissance Fair in Shakopee (August-September); Minnesota State Fair in St. Paul (August-September); Dozinky: A Czechoslovakian Harvest Festival, in New Prague (September).

October-December
Halloween Festival in Anoka (October); Oktoberfest in New Ulm (October); Fish House Parade in Aitkin (November); Holidazzle Parades in Minneapolis (November-December); Folkways of Christmas in Shakopee (December).

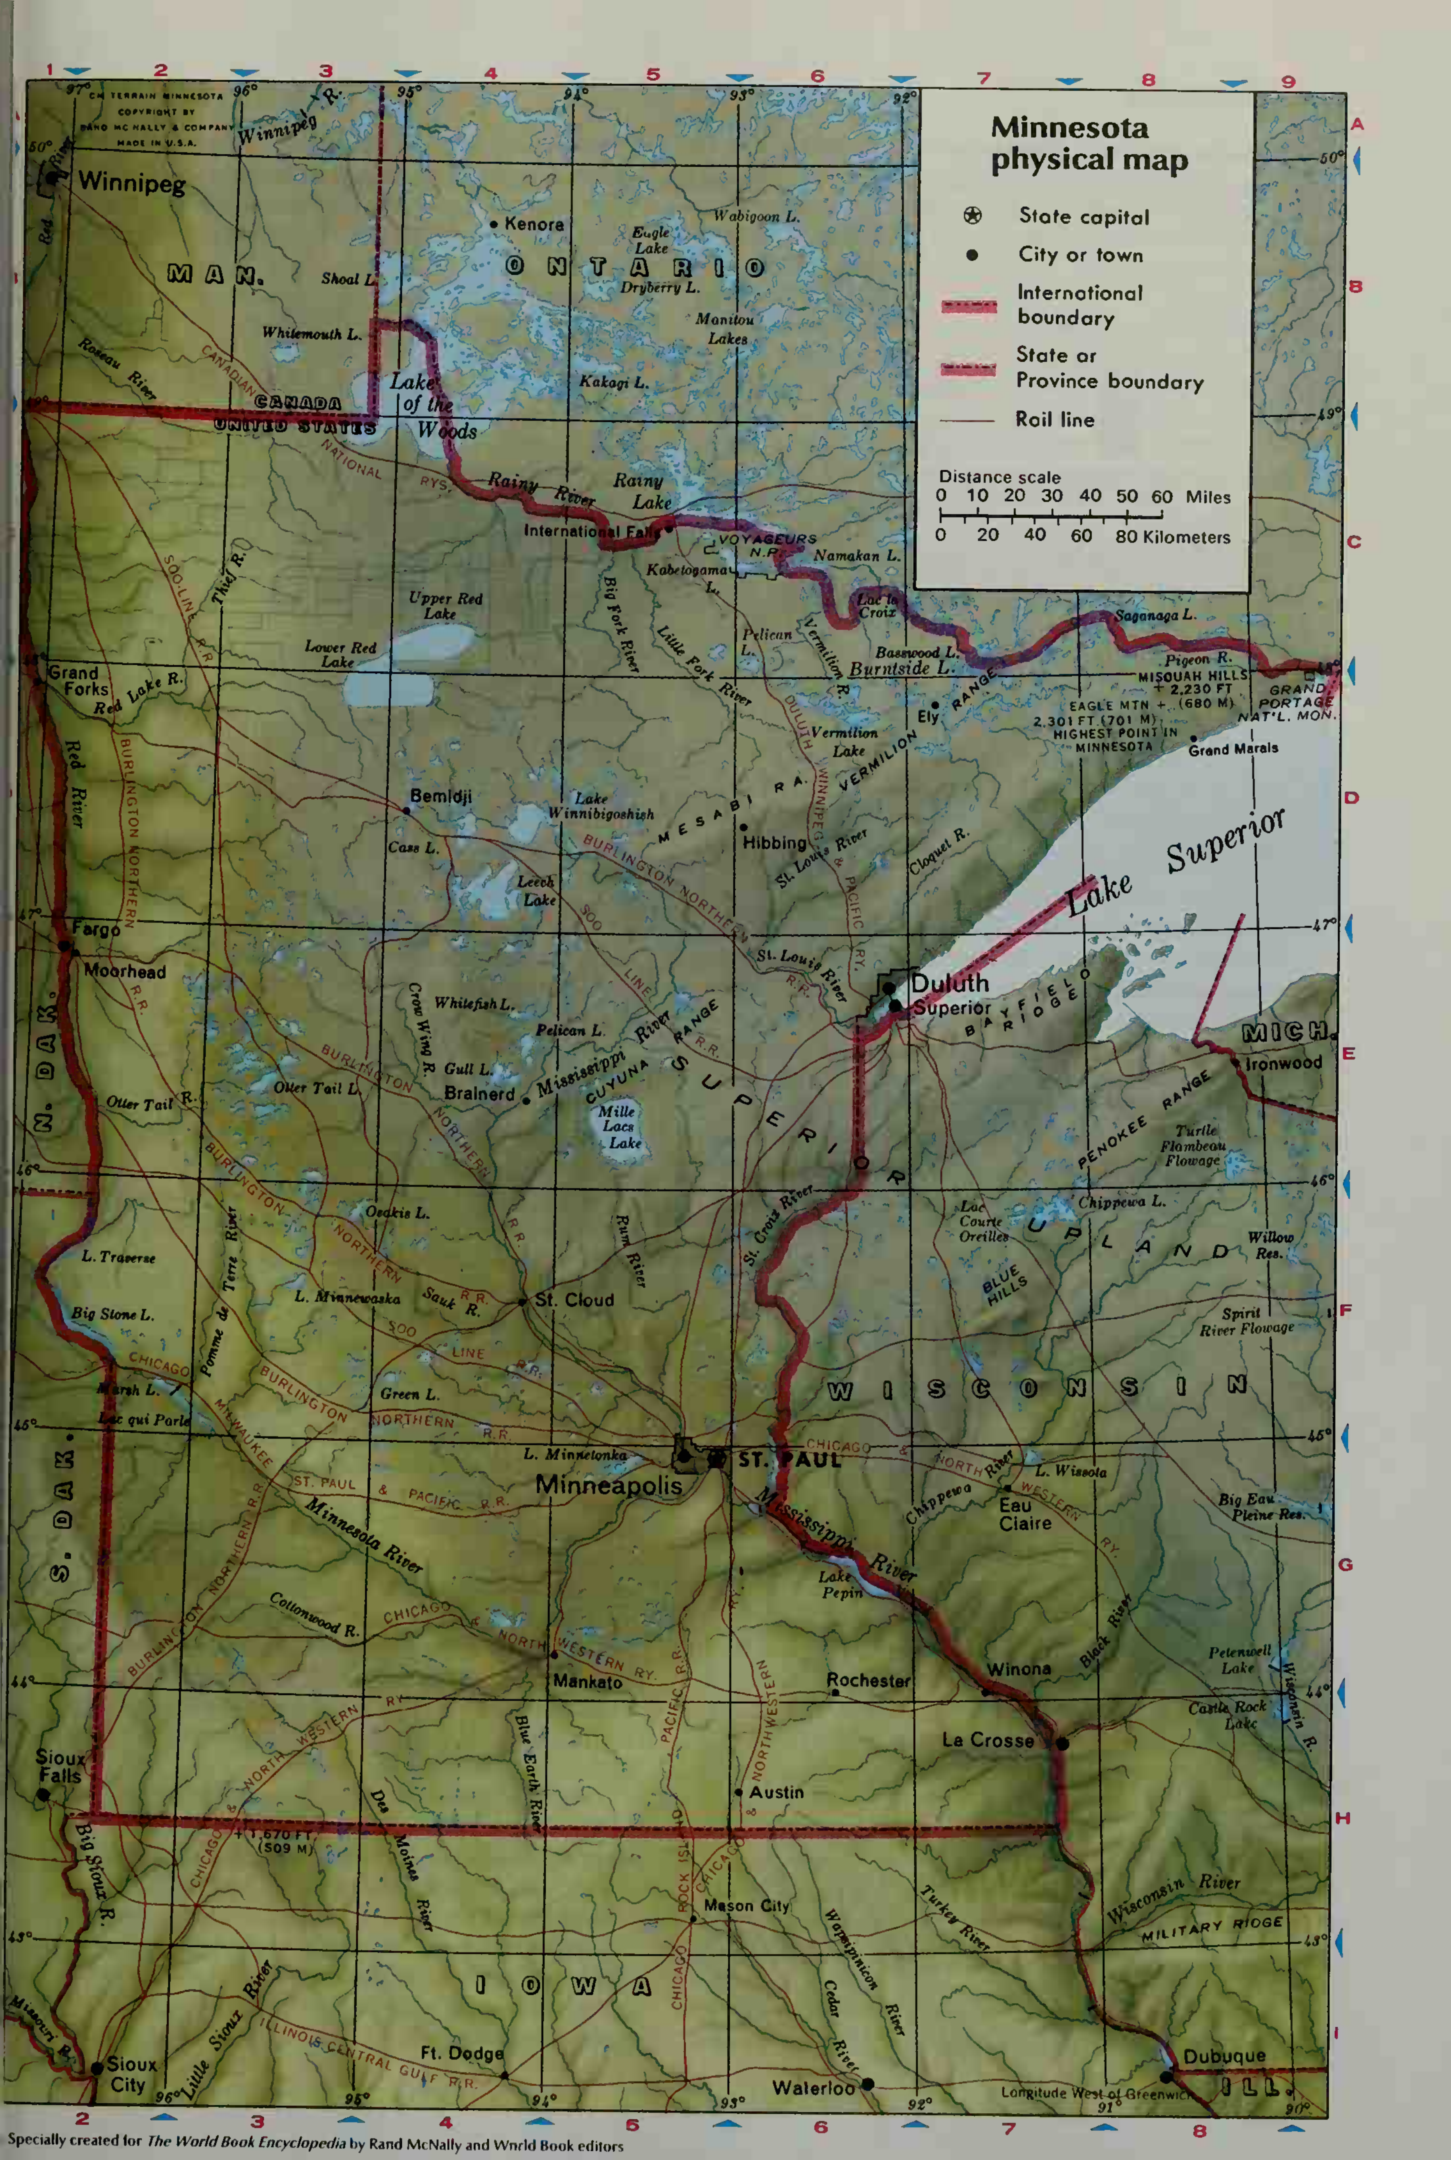
Land and climate

The Boundary Waters area, in northern Minnesota along the United States-Canadian border, is a thickly forested region dotted with magnificent blue lakes.

Gallery North

During a period of geologic time known as the Pleistocene Epoch, which began about 2 million years ago, a series of glaciers moved across Minnesota. The glaciers last began to retreat less than 20,000 years ago. As the glaciers advanced south and west across Minnesota, they leveled most of the land. Only a small area in the southeast was untouched. The glaciers created gently rolling plains over most of the state. Thousands of low places formed by the glaciers filled with water. These places became lakes, swamps, or marshes.

Land regions. Minnesota has four major land regions: (1) the Superior Upland, (2) the Young Drift Plains, (3) the Dissected Till Plains, and (4) the Driftless Area.



The Superior Upland is part of the southern tip of the Canadian Shield. The Canadian Shield is a vast area lying over old, hard rock (see **Canadian Shield**). The glaciers had less effect on the hard rock of the Superior Upland than on most other regions of the state. That is why this region includes the most rugged part of Minnesota. The area just north of Lake Superior is the roughest, most isolated part of the state. Eagle Mountain in Cook County is 2,301 feet (701 meters) high. It is Minnesota's highest point. The northeastern tip of the Superior Upland has an arrowhead shape, and is called the *Arrowhead Country*. Most of Minnesota's iron ore deposits are in the Superior Upland.

The Young Drift Plains consist mainly of gently rolling farmlands. Glaciers smoothed the surface of this region and deposited great amounts of fertile topsoil called *drift* as they melted. The region has some of the nation's richest farmland, and it is the most important farming area in Minnesota. Parts of the Drift Plains are sandy or stony, and not so well suited for crop farming. *Moraines* can be found in some places, especially in central Minnesota. These are deposits of stones and other earth materials pushed before or along the sides of the glaciers. The moraine areas are hilly and have many lakes. The northernmost tip of the Drift Plains was once part of the bed of Lake Agassiz, a huge lake that drained away after the end of the Ice Age (see **Lake**

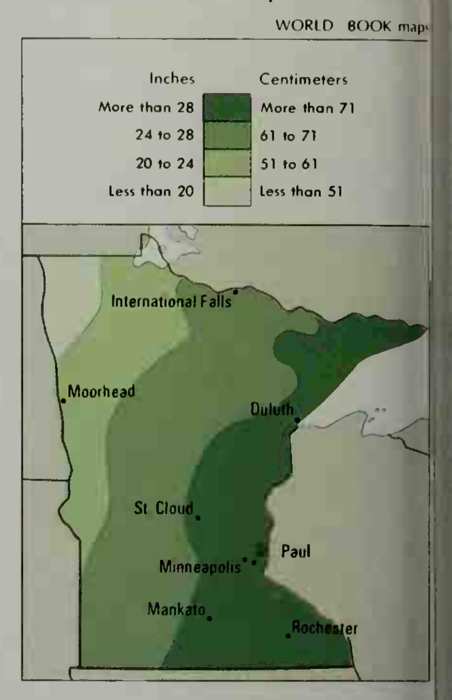
Average January temperatures

Minnesota winters can be bitterly cold. International Falls frequently has the lowest daily temperature in the nation.

Average July temperatures



Minnesota generally has even temperatures during the summer. The southern half of the state is the warmest.

Average yearly precipitation

The east has the greatest amount of precipitation. The amount decreases steadily toward the northwestern part of the state.

Agassiz). Marshlands and wooded areas lie in parts of this northern section. But most of it is a level and almost treeless plain.

The Dissected Till Plains cover the southwestern corner of Minnesota. There, the glaciers left a thick deposit of *till*—a soil-forming material of sand, gravel, and clay. Streams have *dissected* (cut up) the region. The few level areas in the Dissected Till Plains make excellent farmland.

The Driftless Area lies along the Mississippi River in the southeastern corner of the state. Although glaciers never touched this region, the western part is almost flat. Swift-flowing streams have cut deep valleys into the eastern part of the Driftless Area, giving it a broken surface.

Lakes, rivers, and waterfalls. Minnesota has one of the greatest water areas of any state. Its thousands of inland lakes cover more than 4,750 square miles (12,300 square kilometers)—over a twentieth of the state's area. The number of lakes in Minnesota has been estimated as high as 22,000. There are more than 15,000 known lake basins in the state that cover 10 acres (4 hectares) or more. But opinions differ on how large a body of water must be to be properly called a lake.

The largest lake within the state, Red Lake, covers 430 square miles (1,110 square kilometers). Other big lakes in northern Minnesota include Cass Lake, Lake of the Woods, Leech Lake, Vermilion Lake, and Winnibigoshish Lake. Large lakes elsewhere in the state include Big Stone Lake and Lake Traverse, in western Minnesota; and Mille Lacs Lake and Lake Minnetonka, near the center of Minnesota.

Lake Itasca, in north-central Minnesota, is the source of the mighty Mississippi River. It flows out of the lake as a small, clear stream about 10 feet (3 meters) wide and less than 2 feet (61 centimeters) deep.

The Mississippi River and its branches drain about 57 per cent of Minnesota. The Mississippi's chief branches include the Crow Wing, Minnesota, Rum, St. Croix, and Sauk rivers. The Rainy River and the Red River of the North drain the northern and northwestern areas of Minnesota. The St. Louis River and other rivers that empty into Lake Superior drain the land that lies north of the lake.

One of Minnesota's most beautiful waterfalls is Minnehaha Falls, on Minnehaha Creek in Minneapolis. Henry Wadsworth Longfellow made this 53-foot (16-meter) falls famous in his poem *The Song of Hiawatha.* The 49-foot (15-meter) Falls of St. Anthony, on the Mississippi River in Minneapolis, was an important source of power in the early development of Minneapolis. The highest waterfall entirely within the state is 124-foot (38-meter) Cascade Falls, on the Cascade River in Cook

County. Another famous waterfall is High Falls, on the Pigeon River along the Minnesota-Ontario border. High Falls drops 133 feet (41 meters).

Plant and animal life. Forests cover about 35 percent of Minnesota. Aspen, balsam fir, pine, spruce, and white birch grow in the northern part of the state. Scattered groves of ash, black walnut, elm, maple, and oak grow in the south.

Blackberries, lilies of the valley, raspberries, rue anemones, wild geraniums, and wild roses are found in northern Minnesota. Blueberries, honeysuckles, sweet ferns, trailing arbutus, and wintergreen cover natural openings in the pine forests.

Wildflowers grow in the southern, western, and northwestern parts of Minnesota. These flowers include asters, bird's-foot violets, blazing stars, goldenrod, and prairie phlox.

White-tailed deer can be found over most of the state. Black bears and moose roam the woods and swamps of the north. Smaller animals found in various parts of Minnesota include beavers, bobcats, foxes, gophers, minks, muskrats, raccoons, and skunks. Quail and ring-necked pheasants feed in the grainfields. Ducks nest in the lakes and swamps during the summer. Fish in Minnesota waters include bass, northern pike, sunfish, trout, and walleye.

Climate. In July, Minnesota averages 68 °F (20 °C) in the north and 74 °F (23 °C) in the south. The record high, 114 °F (46 °C), was set at Beardsley on July 29, 1917, and at Moorhead on July 6, 1936. January temperatures average 2 °F (−17 °C) in the north and 15 °F (−9 °C) in the south. The record low, −60 °F (−51 °C), was set at Tower on Feb. 2, 1996.

Northwestern Minnesota has about 19 inches (48 centimeters) of *precipitation* (rain, melted snow, and other forms of moisture) each year. The southeast receives about 32 inches (81 centimeters) of precipitation a year. Snowfall averages 20 inches (51 centimeters) annually in the southwest and 70 inches (180 centimeters) in the northeast.

Economy

Service industries, taken together, make up the greatest portion of Minnesota's *gross state product*—the total value of all goods and services produced in a state in a year. Minnesota is internationally recognized as a center of health care and medicine. The state's economy benefits from spending by thousands of tourists each year. Manufacturing also plays an important role in the state's economy.

Natural resources of Minnesota include fertile soil, important minerals, and thick evergreen forests.

Soil is Minnesota's most important natural resource because it is the basis of the state's great farm economy. Minnesota has several types of soil. Most of them were formed from the drift deposited by the glaciers. The color and fertility of the soil indicate the direction from which the ice sheets came. Drift brought from the north was generally gray and more fertile. Drift from the northeast was reddish and less fertile. In some places, different kinds of drift were deposited in layers or mixed. In parts of southern Minnesota, the wind deposited a fine, silty material called *loess* on top of the drift. The loess formed a fertile, rock-free topsoil.

Minerals. The Mesabi Range, in Itasca and St. Louis counties, yields all of Minnesota's iron ore. Most of the ore mined in the Mesabi Range comes from a rock called *taconite* (see **Taconite**). Ore from the Cuyuna Range, located just north of Mille Lacs Lake, contains manganese, an important element in steelmaking. Large deposits of granite are found near St. Cloud and along the upper Minnesota River. Quarries in the southern part of Minnesota produce limestone and sandstone. Sand and gravel are found throughout the state.

Forests cover about 35 percent of Minnesota. Forests of jack, Norway, and white pine grow in the north. Other northern trees include the aspen, balsam fir, spruce, and white birch. Scattered groves of ash, black walnut, elm, maple, and oak trees grow in the southern part of the state.

Service industries account for the largest part of the gross state product of Minnesota. Most of these industries are concentrated in the metropolitan areas.

Community, business, and personal services rank first among Minnesota's service industries in terms of the gross state product. These services also employ more people in Minnesota than any other industry. Community, business, and personal services include private health care, computer programming and data processing, legal services, and automobile repair. Rochester is the home of the Mayo Clinic, one of the world's largest medical centers. The Twin Cities are home to several private health-care facilities and the University of Minnesota, a leader in organ transplants.

Ranking next among the state's service industries are (1) wholesale and retail trade and (2) finance, insurance, and real estate. Each of these two industry groups ac-

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers	
		Number of people	Percent of total
Community, business, & personal services	21	988,300	30
Wholesale & retail trade	18	712,100	22
Manufacturing	18	458,000	14
Finance, insurance, & real estate	18	246,500	8
Government	10	382,100	12
Transportation, communication, & utilities	8	151,700	5
Construction	5	155,200	5
Agriculture	2	128,700	4
Mining	†	9,700	†
Total	100	3,232,300	100

*GSP = gross state product, the total value of goods and services produced in a year.
†Less than one-half of 1 percent.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

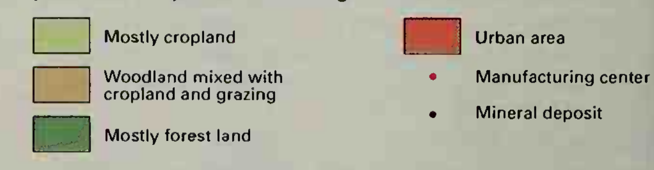
counts for an equal share of the gross state product.

The wholesale trade of automobiles, farm products, and groceries is important in Minnesota. Leading retail businesses include discount stores, food stores, and restaurants. Two of the nation's top retailing companies, Target Corporation and SuperValu Stores, are based in the Twin Cities area. Duluth is a major center of wholesale and retail trade.

Minneapolis is the state's center of finance, insurance, and real estate. Real estate is the leading part of this industry because of the large sums of money involved in the buying and selling of homes and other buildings. The Minneapolis area is the headquarters of several major U.S. banks, holding companies, and insurance firms. Several large insurance companies are based in St. Paul.

Government is the fourth-ranking service industry in Minnesota. Government services include the operation of public schools and hospitals, and of military bases.

Transportation, communication, and utilities form the state's fifth-ranking service industry. Northwest Airlines is based in Eagan. Utilities provide gas, electric, and water service. More information about transportation and communication appears later in this section.



Manufacturing. Goods produced in Minnesota have a *value added by manufacture* of about $39 billion yearly. This figure represents the increase in value of raw materials after they become finished products.

Computer and electronic products are the leading type of manufactured product in Minnesota in terms of value added by manufacture. Computers manufactured in the state range in size from small desktop models to gigantic supercomputers. Telephone and other communications equipment are also major manufactures from the electronic products sector. The state's electronic products also include medical devices developed by the state's advanced health care research facilities.

Food products rank second. Meat packing is the

Economy of Minnesota

This map shows the economic uses of land in Minnesota and where the state's leading farm, mineral, and forest products are produced. Major manufacturing centers are shown in red.

WORLD BOOK Map

state's most important food-processing activity, and Minnesota is a leading meat-packing state. Most large plants are in the southern part of the state. The state is also a leading producer of flour. Its factories produce large amounts of cake mixes and breakfast cereals. Minnesota ranks high among the states in milk, butter, and cheese production. The state is a top producer of canned vegetables. Most of the canning plants are in southern Minnesota. Sugar-beet refineries operate in the Red River Valley and along the Minnesota River.

Machinery ranks third among the manufactured products of Minnesota. Machinery for agriculture, metalworking, and heating and cooling is manufactured in the state. The state's factories also make machines for making computer microchips.

Fabricated metal products rank fourth among Minnesota's manufactured products. Major types of metal products made in Minnesota include weapons and ammunition, cans, and stampings.

Other types of products made in Minnesota include paper products, printed materials, transportation equipment, and wood products. Cloquet and Grand Rapids have large paper mills, and Hutchinson has a large plant that manufactures adhesive tape. Commercial printing shops, newspaper publishers, and book publishers produce most of the printed materials. St. Paul, Minneapolis, Mankato, and Duluth are the major printing centers.

Minnesota Department of Energy and Economic Development

Workers prepare corn on the cob in a processing plant in Le Sueur. Minnesota ranks as one of the leading agricultural states. It is sometimes called the *Bread and Butter State.*

Automobiles, trucks, and buses are major types of transportation equipment made in Minnesota. Factories in the state also manufacture a variety of aircraft parts. Plywood is the state's leading wood product.

Agriculture. Minnesota ranks among the leading states in annual farm income. Farmland covers a little more than half the state. Minnesota has approximately 80,000 farms.

Thousands of Minnesota farmers sell their produce through farm cooperatives. Most of them are dairy cooperatives, but many handle grain and livestock. See **Cooperative**.

Livestock and livestock products provide about half of Minnesota's annual income from farm products. Hogs are the state's most valuable livestock product. Minnesota ranks among the leaders in hog production.

Dairy and beef cattle are also important sources of livestock income in Minnesota. Minnesota has more than 800,000 dairy cattle. It ranks as one of the leading milk-producing states. Most of Minnesota's milk is made into butter and cheese. The southwestern part of the state has the most cattle and hog farms. The state is also an important producer of eggs and turkeys.

Crops account for about half of Minnesota's farm income. Corn is the state's most valuable field crop. Soybeans rank as the second most valuable crop. Minnesota is a leading state in the production of both corn and soybeans. Both of these crops are grown throughout southern Minnesota. Farmers also grow hay in the southern part of the state. Much of Minnesota's corn, hay, and soybeans is used as feed for livestock. Sugar beets are grown in southern and western Minnesota. The Red River Valley of northwestern Minnesota is famous for its huge wheat crops.

Other field crops grown in Minnesota include barley, flaxseed, and oats. Peas, potatoes, and sweet corn are the state's leading vegetable crops. Apples are the leading fruit crop.

Mining. Iron ore provides most of Minnesota's mining income. Minnesota leads the states in iron ore production. But the importance of iron ore mining to the Minnesota economy declined greatly during the late 1900's. Most of the remaining iron ore is a low grade called *taconite.* It is mined in northeastern Minnesota.

Quarries in central Minnesota yield unusually fine granite. Limestone is taken from extensive deposits in southern Minnesota. Clay comes from many areas of Minnesota, and is used in making bricks and tile. Sand and gravel are also produced throughout the state.

Fishing industry. Fishing, both recreational and commercial, is a major activity in the state. The most valuable fishes taken from the Mississippi River include buffalo fish, carp, catfish, whitefish, and yellow perch. Lake herring, smelt, walleye, and yellow pike are the chief products of the Lake Superior catch.

Electric power. About two-thirds of Minnesota's electric power is produced by plants that burn coal. Nuclear plants generate about one-fourth of the state's electric power. Minnesota has two nuclear power plants at Prairie Island near Red Wing and one at Monticello. In addition, hydroelectric plants and plants that burn natural gas or petroleum generate a small amount of the state's power. Minnesota must purchase some electric power from other states and from Canada to fulfill its needs.

Transportation. Minnesota's great network of rivers and lakes provided transportation for the explorers, fur traders, missionaries, and settlers who first entered the region. In the 1820's, the first steamboats sailed on the upper Mississippi. Railroad construction in the state progressed rapidly after 1865. Today, 12 rail lines provide freight service, and passenger trains serve several cities. The Twin Cities form the chief rail center of the Upper Mississippi Valley. They also have the state's busiest airport.

About 130,000 miles (209,000 kilometers) of roads and highways cross the state. The nation's largest bus system, Greyhound Bus Lines, had its start in Hibbing in 1914.

Barges bring coal, oil, and other products to Minnesota ports which lie on the Minnesota, Mississippi, and St. Croix rivers. The barges return with grain and other products from Minnesota. Much of Minnesota's water traffic is on Lake Superior. The harbor at Duluth and Superior, Wisconsin, is the busiest freshwater port in North America and one of the busiest freshwater ports in the world. Grains, iron ore, and coal make up most of the outgoing cargo from this port.

Communication. In 1849, James Madison Goodhue began publishing Minnesota's first newspaper, the *Minnesota Pioneer,* in St. Paul. Today, Minnesota has about 20 daily newspapers and about 300 weekly newspapers. The daily newspapers with the largest circulations include the *Rochester Post-Bulletin,* the *Star Tribune* in Minneapolis, and the *St. Paul Pioneer Press.* Minnesota also publishes about 200 periodicals.

Minnesota's first licensed radio station was WLB (now KUOM), an educational station owned by the University of Minnesota. The station was licensed in Minneapolis in 1922. The first commercial radio station, WDGY, began broadcasting from Minneapolis in 1923. KSTP-TV, Minnesota's first television station, started broadcasting in Minneapolis in 1948. Minnesota now has about 200 radio stations and 25 television stations. Cable television systems and Internet providers serve many communities across the state.

Government

Constitution. Minnesota is still governed under its original constitution, adopted in 1858. The Constitution may be *amended* (changed) in two ways. An amendment may be proposed in the Legislature, where it must be approved by a majority of the lawmakers. Next, the amendment must be approved by a majority of the voters in an election.

The Constitution may also be amended by a constitutional convention. A proposal to call such a convention must be approved by two-thirds of the Legislature and by a majority of the voters in an election. Proposals made by a convention become law after they have been approved by three-fifths of the voters casting ballots on the proposals.

Executive. The governor of Minnesota is elected to hold office for a four-year term. The governor can be re-elected any number of times. The lieutenant governor, secretary of state, attorney general, treasurer, and auditor are also elected to four-year terms. The governor appoints the heads of most state departments, boards, and commissions. These officials are appointed to serve terms that range from two to six years.

Legislature consists of a 67-member Senate and a 134-member House of Representatives. Each senator and representative is elected from a separate district. Most senators serve four-year terms. But senators elected in years that can be divided by 10 serve two-year terms to allow for *reapportionment* (redrawing of districts). All representatives serve two-year terms. The legislature begins its regular session on the Tuesday after the first Monday in January in odd-numbered years. The Constitution of Minnesota limits regular legislative sessions to 120 legislative days over a two-year period. The governor may call special legislative sessions.

Courts. The state Supreme Court, Minnesota's highest court, has a chief justice and six associate justices. The chief justice and the associate justices are elected to six-year terms. In 1982, Minnesota adopted a state constitutional amendment that established a Court of Appeals. The court consists of 16 judges, who are elected to six-year terms.

Minnesota has one district court. It is divided into 10 judicial districts. Each judicial district has three or more judges, who are elected to six-year terms. The district court handles criminal and civil cases. The judicial districts in Hennepin and Ramsey counties also handle cases involving juveniles.

Local government. Minnesota has 87 counties. Each is governed by a board of commissioners, usually consisting of five members. The board's powers include borrowing money, collecting taxes, and deciding how to spend funds. Board members are elected to four-year terms. Other county officials in Minnesota include the attorney, auditor, medical examiner or coroner, sheriff, and treasurer. These officials also serve four-year terms.

Minnesota has more than 850 cities. The state constitution allows cities to adopt *home-rule* charters. This means that a city may choose the form of government best suited to its needs. About 100 cities operate under home-rule charters. Most Minnesota cities use the mayor-council form of government. The rest use the commission or council-manager form.

There are about 1,800 organized townships in Minnesota. Each township is governed by a board of supervisors. The voters elect the supervisors to three-year terms at an annual township meeting.

Revenue. Taxes bring in about 60 percent of the state government's *general revenue* (income). Most of the rest comes from federal grants and programs. A tax on personal income and a general sales tax provide most of the tax revenue. Other sources of tax revenue include taxes on corporate income, motor fuels, and motor vehicle licenses.

Politics. During most of its early history, Minnesota strongly favored Republicans for state offices and for President. Between 1858 and 1931, Minnesota had only four Democratic governors. For Minnesota's electoral votes and voting record in presidential elections, see **Electoral College** (table).

In 1918, a third party, the Farmer-Labor Party, was

Minnesota House of Representatives

Minnesota's House of Representatives meets in the House Chambers in St. Paul. The Minnesota House consists of 134 members. Representatives serve two-year terms.

The governors of Minnesota

	Party	Term
Henry H. Sibley	Democratic	1858-1860
Alexander Ramsey	Republican	1860-1863
Henry A. Swift	Republican	1863-1864
Stephen Miller	Republican	1864-1866
William R. Marshall	Republican	1866-1870
Horace Austin	Republican	1870-1874
Cushman K. Davis	Republican	1874-1876
John S. Pillsbury	Republican	1876-1882
Lucius F. Hubbard	Republican	1882-1887
Andrew R. McGill	Republican	1887-1889
William R. Merriam	Republican	1889-1893
Knute Nelson	Republican	1893-1895
David M. Clough	Republican	1895-1899
John Lind	Democratic	1899-1901
Samuel R. Van Sant	Republican	1901-1905
John A. Johnson	Democratic	1905-1909
Adolph O. Eberhart	Republican	1909-1915
Winfield S. Hammond	Democratic	1915
Joseph A. A. Burnquist	Republican	1915-1921
Jacob A. O. Preus	Republican	1921-1925
Theodore Christianson	Republican	1925-1931
Floyd B. Olson	Farmer-Labor	1931-1936
Hjalmar Petersen	Farmer-Labor	1936-1937
Elmer A. Benson	Farmer-Labor	1937-1939
Harold E. Stassen	Republican	1939-1943

*Democratic-Farmer-Labor. †Independent-Republicans.

founded in Minnesota. It soon became powerful. In 1944, the Farmer-Labor Party joined with the Minnesota Democratic Party to form the Democratic-Farmer-Labor Party (DFL).

Hubert H. Humphrey, a DFL leader, served in the U.S. Senate from 1949 to 1964 and from 1971 to 1978. Humphrey was Vice President of the United States from 1965 to 1969. He was the Democratic nominee for President in 1968, but lost. Walter F. Mondale of Minnesota also served as Vice President and as a U.S. senator. He was the Democratic nominee for President in 1984, but he lost the election.

In 1975, the Republican Party of Minnesota changed its name to Independent-Republicans of Minnesota. Both the DFL and the Independent-Republicans have much strength in Minnesota today.

History

Indian days. White people first entered the Minnesota region in the last half of the 1600's. They found Sioux Indians in the northern forests. The Sioux lived in dome-shaped wigwams and were skilled hunters. By 1750, large numbers of Chippewa Indians were moving westward into Minnesota. The Chippewa Indians took over the northern forests of the region, and they forced the Sioux to move to the southwest. The Sioux became wanderers, and the two tribes remained enemies for many years.

Exploration. Two famous French fur traders, Pierre Esprit Radisson and Médard Chouart, Sieur des Groseilliers, were the first white men to set foot in Minnesota. They arrived in the area near what is now Two Harbors about 1660.

Another Frenchman, Daniel Greysolon, Sieur Duluth (or Du Lhut), entered Minnesota in 1679. Duluth was an adventurer who hoped to find a water route to the Pacific Ocean. Duluth landed on the western shore of Lake Superior, and then pushed on into the interior of Minnesota. He claimed the entire region for King Louis XIV of France.

In 1680, Father Louis Hennepin, a Belgian missionary, set out from the Illinois region to explore the upper Mississippi. But Sioux Indians captured Hennepin and his two companions. The Indians took them into Minnesota. Although a captive, Hennepin saw much of the region. He became the first white man to visit the site of present-day Minneapolis, where he sighted and named the Falls of St. Anthony. Meanwhile, Duluth heard that Indians had captured three white men. He found the Indians and successfully demanded that they release the captives.

Struggle for control. In 1762, France gave Spain all its land west of the Mississippi River, including much of Minnesota. But the Spaniards did not try to explore or settle the region, and French trappers continued to collect furs there. In 1763, the French and Indian War ended. France lost this war with Britain over rival claims in North America. France gave Britain almost all its land east of the Mississippi, including eastern Minnesota. During the next 50 years, the North West Company and other British fur-trading firms established posts in the region.

In 1783, the Revolutionary War ended. Britain gave its land that was south of the Great Lakes and east of the Mississippi River to the United States. This vast area became part of the Northwest Territory, which Congress created in 1787. However, British fur companies continued to trade in the region. The United States did not gain full control of the Northwest Territory until after the War of 1812.

The Louisiana Purchase. In 1800, Napoleon Bonaparte forced Spain to return the region west of the Mississippi River to France. France sold this region, called Louisiana, to the United States in 1803 (see **Louisiana Purchase**). Two years later, Zebulon M. Pike was sent to explore the upper Mississippi and the Minnesota wilderness.

In 1819, the U.S. Army established a fort in temporary buildings. In 1820, American soldiers began building Fort St. Anthony as a permanent fort at the point where

Royal Ontario Museum, Toronto

Fort Snelling in southeastern Minnesota protected settlers and traders in the early 1800's. Canadian artist Paul Kane painted a view of the fort in *Fort Snelling, Sioux Scalp Dance, left.*

Immigrants from Germany, Norway, Sweden, and other European countries came to Minnesota during the 1870's, 1880's, and 1890's. Many became farmers or railroad workers.

Brooks, Minnesota Historical Society

the Minnesota and Mississippi rivers meet. The fort was completed in 1825 and renamed Fort Snelling. It became a center of industry and culture, as well as of military duty. Explorers often used Fort Snelling as a base from which they set out for undiscovered parts of Minnesota. These explorers included Stephen H. Long, William H. Keating, and George W. Featherstonhaugh. In 1832, Henry R. Schoolcraft discovered and named Lake Itasca, the source of the Mississippi River.

Lumbering began in the St. Croix Valley during the late 1830's. In 1837, the Sioux and Chippewa Indians sold their claims to the logging area around the St. Croix River to the U.S. government. Lumberers and settlers soon moved to the area. Settlers founded Minnesota's first towns—St. Paul, St. Anthony (which later merged with Minneapolis), and Stillwater.

Territorial days. Through the years, parts of Minnesota had belonged to the territories of Illinois, Indiana, Iowa, Michigan, Missouri, and Wisconsin, and to the territory and district of Louisiana. On March 3, 1849, Congress created the Minnesota Territory. Its southern, northern, and eastern boundaries were the same as those of the state today. The western boundary extended to the Missouri and White Earth rivers. Alexander Ramsey was appointed as the first territorial governor. About 4,000 white people lived in Minnesota when it became a territory.

In 1851, the Sioux Indians, under pressure from the U.S. government, signed two treaties giving up their rights to a vast area west of the Mississippi River. Most of the land was in southern Minnesota. This new rich territory was opened to white settlement, and newcomers poured in.

Statehood. On May 11, 1858, Congress admitted Minnesota into the Union as the 32nd state. The people elected Henry H. Sibley as the first governor of their state. Sibley had been an agent of the American Fur Company, and had worked for the creation of the Minnesota Territory. Minnesota had a population of about 150,000 when it became a state.

The Civil War began in 1861. Minnesota became the first state to offer troops for the Union armies. In August 1862, when many Minnesota men were away fighting for the Union, the Sioux—then confined to reservations —went to war against the pioneers. The Indians swooped down on frontier towns, killing about 500 settlers and destroying much property. Federal troops helped Minnesota militiamen put down the uprising.

Industrial development occurred rapidly in Minnesota after the Civil War ended in 1865. Railroads expanded across the state, and the old Sioux hunting grounds became wheat lands. Flour mills sprang up throughout the wheat region, but most were in the Minneapolis area. These mills produced such huge quantities of flour that Minneapolis was known as the *Mill City.*

Minnesota waged a vigorous drive to attract newcomers. The state government and the railroads sent pamphlets to Europe, describing the opportunities in Minnesota. During the 1870's, 1880's, and 1890's, thousands of immigrants, especially Germans, Norwegians, and Swedes, settled in the state.

The outstanding event of the late 1800's was the development of rich iron ore resources. In 1884, the first ore was shipped from the Vermilion Range. In 1890, workers employed by Leonidas Merritt and several of his seven brothers discovered ore near Mountain Iron in the Mesabi Range. Two years later, after involving other relatives in their venture, the Merritts shipped the first load of ore from the Mesabi Range.

In 1889, William W. Mayo and his two sons, William and Charles, established the Mayo Clinic in Rochester. The clinic's fame spread rapidly, and the Mayos turned it into a general medical center. The clinic became one of the world's leading medical research centers.

In 1894, a great forest fire swept across about 400 square miles (1,000 square kilometers) of eastern Minnesota. It wiped out the villages of Hinckley and Sandstone. More than 400 people were killed, and property valued at over $1 million was destroyed.

The early 1900's. In 1911, the first shipment of iron ore left the Cuyuna Range. In December 1915, the first operations began at a huge steel mill in Duluth. After the United States entered World War I in 1917, there were heavy demands for Minnesota's products. Great crops of wheat and other grains were raised to feed the armed forces. Iron ore production totaled almost 90 million short tons (82 million metric tons) during 1917 and 1918.

In 1918, Minnesota was struck by another disastrous forest fire. Strong winds fanned a number of small fires into one huge fire that roared across large areas of Carlton and St. Louis counties in the northeast. The fire killed more than 400 people and destroyed property valued at about $25 million.

During the 1890's and early 1900's, many Minnesota farmers joined cooperatives. They joined together to

Historic Minnesota

The source of the Mississippi River was discovered in 1832 by Henry Schoolcraft, an American explorer. He traced the river to its origin at Lake Itasca in northwestern Minnesota.

The first flour mill in Minnesota was built at the Falls of St. Anthony in 1823. Minneapolis was one of the world's leading flour centers by the 1870's.

Rich iron deposits were discovered in Minnesota in 1865 by geologist H. H. Eames. The Vermilion Range was first mined in 1884; the Mesabi Range in 1892.

The Mayo Clinic was established at Rochester in 1889 by William W. Mayo and his two sons, William and Charles. It is a leading medical research center.

Sinclair Lewis, an American novelist, was born in Sauk Centre in 1885. He became the first American to win the Nobel Prize for literature.

Important dates in Minnesota

c. 1660 Pierre Esprit Radisson and Médard Chouart, Sieur des Groseilliers, visited the Minnesota region.

1679 Daniel Greysolon, Sieur Duluth, explored the western shore of Lake Superior.

1680 Louis Hennepin sighted the Falls of St. Anthony.

1783 Great Britain granted the land east of the Mississippi River to the United States.

1803 The United States obtained the Minnesota area west of the Mississippi through the Louisiana Purchase.

1819-1825 The U.S. Army established a fort in temporary buildings in 1819. It built Fort St. Anthony as a permanent fort between 1820 and 1825. The fort was renamed Fort Snelling in 1825.

1832 Henry R. Schoolcraft discovered Lake Itasca, the source of the Mississippi River.

1849 Congress created the Minnesota Territory.

1851 The Sioux Indians gave up their rights to large areas of land west of the Mississippi River.

1858 Minnesota became the 32nd state on May 11.

1862 Minnesota millitiamen and U.S. troops put down a Sioux uprising.

1884 The first shipment of iron ore from the Vermilion Range left Minnesota.

1889 William W. Mayo and his two sons founded the Mayo Clinic in Rochester.

1892 The first ore was shipped from the Mesabi Range.

1944 The Farmer-Labor party joined the Minnesota Democratic party to form the Democratic-Farmer-Labor party.

1964 Minnesota voters approved a constitutional amendment assuring taconite producers that taxes on taconite will not be raised at a higher rate than taxes on other businesses for 25 years.

1982 Minnesota adopted a state constitutional amendment that established the Court of Appeals to relieve the caseload of the state Supreme Court.

provide their own financial and storage services, and transportation for their products. The farmers believed that the railroads, banks, and grain companies charged too much for these services. During the 1920's, the new Farmer-Labor Party supported the farmers. In 1931, Floyd B. Olson became the first Farmer-Labor governor.

The Great Depression of the 1930's hit Minnesota hard. Unemployment was widespread in the cities. About 70 percent of the iron-range workers in the state lost their jobs. Farm income fell sharply. The state government took many steps to fight the depression, and federal agencies were set up to provide employment and relief.

The mid-1900's. Minnesota's economy recovered during World War II (1939-1945). The state's lumber and mining industries turned out huge amounts of raw materials for the armed forces. But the supply of high-grade iron ore suddenly dropped in the 1950's, as did the demand for the ore. The industry declined and several mines closed.

As a result of the mining slump, the state's iron industry began to develop low-grade taconite ore. Taconite contains about 30 percent iron in the form of specks of iron oxide.

In 1964, Minnesota voters approved an amendment to the state constitution that boosted investment in the iron industry. The so-called taconite amendment guaranteed that taxes on taconite would not be raised at a higher rate than taxes on other products for 25 years. Previously, iron-mining companies had been taxed at a higher rate, and producers had delayed plans to build taconite plants. After passage of the taconite amendment, producers invested more than $1 billion in taconite plants.

Many new manufacturing industries began operating in Minnesota during the mid-1900's. The products of these industries include aerospace equipment, chemicals, computers, electronic equipment, and heavy machinery. These developments added *diversification* (variety) to the state's economic base.

In Minnesota, as in other states, the number of farms and farmworkers decreased. Large numbers of families moved from rural areas to cities. By 1950, the state's total urban population had grown larger than the rural population for the first time. In 1964, a federal court ordered Minnesota to *reapportion* (redivide) its legislative districts to give the city population equal representation in the state legislature.

The Farmer-Labor Party joined the state Democratic Party in 1944 to form the Democratic-Farmer-Labor Party (DFL). In 1975, the Republican Party of Minnesota changed its name to Independent-Republicans of Minnesota.

Recent developments. A major problem facing Minnesota today is to find ways to develop the state's many resources while preserving its natural beauty. The state's taconite plants became a source of air and water pollution. In 1978, the Minnesota Supreme Court ordered the Reserve Mining Company of Silver Bay to meet pollution control standards at its taconite-processing plant. In 1980, the company established an on-land waste disposal site and no longer discharged waste into nearby Lake Superior. In the 1980's and 1990's, the state government worked with businesses to have the businesses increase their own pollution control efforts.

The economic diversification that began in Minnesota during the mid-1900's increased in the 1990's. The growth of service industries such as finance, insurance, and real estate contributed to the state's economic strength. William E. Lass and Gordon L. Levine

Minnesota, University of, is a state-supported coeducational institution. Its largest and oldest campus, the Twin Cities campus, is in Minneapolis-St. Paul. The university also has campuses in Crookston, Duluth, and Morris.

The Twin Cities campus awards bachelor's, master's, and doctor's degrees. A special program allows some juniors and seniors to follow individual courses of study. The Twin Cities campus has colleges of agriculture, architecture, biological sciences, education, home economics, liberal arts, natural sciences, pharmacy, and veterinary medicine; institutes of public affairs and technology; schools of dentistry, journalism, law, management, medicine, nursing, and public health; a continuing education and extension division; and a graduate school.

The Duluth campus offers liberal arts, science, and business courses leading to bachelor's and master's degrees. It also has a two-year School of Medicine. The Morris campus is a four-year liberal arts institution. The Waseca campus has two-year programs in business, the food and fiber industries, horticulture, and human services. The Crookston campus offers two-year programs in arts and sciences, agriculture, business, and hospitality and home economics.

Other university facilities include the Hormel Institute in Austin, the Lake Itasca Forestry and Biological Station in Itasca State Park, the Forestry Research Center in Cloquet, the Cedar Creek Natural History Area near Bethel, the Freshwater Biological Research Center in Navarre, the Natural Resources Research Institute in Duluth, and the Rosemount Research Center. The university also has an agricultural experiment station that is made up of six branches.

The University of Minnesota was chartered in 1851 as a preparatory school. The school closed during the Civil War (1861-1865) and reorganized as a four-year college in 1868. Critically reviewed by the University of Minnesota

Minnesota River is a large branch of the Mississippi River. The Minnesota flows through a wide valley that was cut by the outlet of Lake Agassiz, an ancient glacial lake (see **Lake Agassiz**). The Minnesota River rises in the Coteau des Prairies (*Little Hills of the Prairie*), a group of hills that are located in northeastern South Dakota. The river flows southeast to Big Stone Lake on the boundary between South Dakota and Minnesota. It follows Big Stone Lake south to Ortonville. There, the Minnesota River flows southeast to Mankato, Minnesota. The river then turns sharply to the northeast. It flows northeast until it joins the Mississippi River. The Minnesota River enters the Mississippi River south of St. Paul, Minnesota. For location, see **Minnesota** (physical map).

The Minnesota River is 332 miles (534 kilometers) long. It drains an area of about 16,600 square miles (41,400 square kilometers).

Early explorers and fur traders sailed up the Minnesota River in their westward journeys. Today, the river is an important trade route. Thomas J. Baerwald

Minnow is a common name for fish in the carp and minnow family. This is the largest family of freshwater fishes, with about 1,600 species in North America, Europe, Asia, and Africa. Most American minnows are small, less than 6 inches (15 centimeters) long. However, a few grow quite large. The *Colorado squawfish,* which is one of the largest minnows in North America, reaches a length of 2 to 4 feet (61 to 120 centimeters). The *Indian mahseer,* found in rivers and streams throughout India, grows to 9 feet (2. 7 meters) long. Minnows often are difficult to identify because of their uniform size, form, and color.

Minnows are *forage fish*—that is, they furnish the food that allows game fish to reach a large size. Minnows also are used as live bait to catch larger fish. In many places, so many minnows have been caught for bait that there are few left, and some states have outlawed or limited the taking of minnows. Minnows are

Minor is a person who is under legal age. In the United States, the legal age was traditionally 21. However, the 26th Amendment to the U.S. Constitution, ratified in 1971, set the minimum voting age at 18. Since then, many states have lowered the legal age—known as the age of majority or adulthood—to 18. In 45 states, the legal age is now 18. In four others—Alabama, Alaska, Nebraska, and Wyoming—it is 19. The general age of majority is still 21 in Mississippi. All states set 21 as the minimum legal age to possess or drink alcoholic beverages.

Under the law, minors have many privileges that are not given to adults. For example, they are not held responsible for a contract with an adult and can refuse to carry out their part of the bargain. However, minors are usually liable for the reasonable value of certain goods or services that are not provided by a parent, as long as the parent provides essential care. These goods or services, called *necessaries,* include food, clothing, lodging, medical care, and education. The law gives special privileges to minors because they are considered too inexperienced to be fully responsible for their actions. In some states, these privileges can be removed by a court action.

Minors may be held responsible for wrongdoing, such as damages they do to others. However, age and inexperience may be taken into consideration.

Under common law, infants under 7 years old were presumed to be incapable of committing a crime. Between the ages of 7 and 14, this presumption could be rebutted. For children over 14, the presumption was that they had criminal capacity. Punishment today varies with the minor's age and usually differs from that for adults. All U.S. states have special courts for minors (see **Juvenile court**). Aidan R. Gough

Minorca is a Spanish island in the Mediterranean Sea, off the east coast of the mainland of Spain. It is popular with tourists because of its mild climate and pleasant scenery.

Minorca, *mih NAWR kuh,* also spelled *Menorca,* is the second largest island of the Balearic Islands, which lie off the east coast of the mainland of Spain (see **Balearic Islands**). Minorca has an area of 266 square miles (689 square kilometers) and a population of about 57,000. Some iron is mined there. Farm crops include cereals and hemp, and grapes, olives, and other fruits. Metalware, textiles, soap, wine, and sandals are manufactured on the island. Tourism is a major industry. Mahón is the chief city and port. For location, see **Spain** (political map).

Minorca is part of Spain. Both England and France captured the island several times. England ceded Minorca to Spain by the Treaty of Amiens in 1802.

Edward Malefakis

Minority group is a group of people who differ in some ways from the principal group in a society. Members of minority groups may differ from the principal group, also called the *dominant group,* in speech, appearance, or cultural practices. The dominant group also has greater political and economic power than the minority group. In many cases, the dominant group *discriminates* against minorities—that is, it treats them unfairly. Most members of minority groups have fewer economic, political, and social opportunities than members of the dominant group have.

Social scientists refer to minorities as racial or ethnic minorities. In sociology, a *racial minority* is identified chiefly by one or more distinctive physical characteristics that are shared by members of the group. These may include skin color, type of hair, body structure, and shape of the head or nose. Most anthropologists today reject the idea that the human population can be broken into biologically defined races. However, socially defined racial classifications persist in many societies. Blacks are considered a racial minority in the United States. An *ethnic minority* is identified chiefly by distinctive cultural practices. For example, its language or speaking accent, religion, or manner of living is differ-

ent from that of the dominant group. The Amish people of the United States and Canada are an ethnic minority. Many Amish dress in plain styles that are different from the clothing worn by most Americans.

Some minority groups combine the characteristics of both racial and ethnic minorities. For example, most Chinese in California in the 1850's were distinguished from other Americans both by their skin and by such cultural characteristics as their language and the style of their clothing.

People in society, especially the members of the dominant group, decide which cultural and physical characteristics are important enough to distinguish people as minorities. For example, the dominant group might decide to use skin color but to ignore hair.

The term *minority* often means *less than half of the whole*. When applied to people, however, the term does not necessarily refer to numerical proportion. Some minority groups actually have more members than the dominant group. For example, blacks form a majority of the population in some cities and counties of the Southern United States. But these blacks have considerably fewer economic and political opportunities than the dominant white group. Thus, blacks in these areas form a *subordinate* (less powerful) group.

How a group becomes a minority

Many minority groups develop when people leave their homeland and settle in another society. Members of the minority may move into the territory of the dominant group either voluntarily or against their will. Or the dominant group may move in and take over the minority's territory. When these groups meet, the dominant group uses its greater economic and military power or other strength to control the minority group.

The enclosing of a minority group within the territory of a dominant group is called *incorporation*. The importing of black Africans to North and South America as slaves from the 1600's to the 1800's was an example of forced incorporation. Immigration is a type of voluntary incorporation. The United States has admitted millions of non-English immigrants from Europe since the late 1700's, and many of these people have become minority groups. Incorporation also occurs when one group annexes territory that adjoins its own. During the 1840's, for example, the United States gained many Spanish-speaking persons when it annexed areas that formerly belonged to Mexico. Annexation has played an especially important role in the history of some European nations. For example, Estonians, Turkish Muslims, and certain other large groups became minorities after czarist Russia annexed their lands.

Some minority groups have resulted from *colonialism*. In colonialism, one nation sends some of its members to gain control over another people's land. This land, which becomes a colony, is used as a source of wealth for the settlers' homeland. The colony's original inhabitants, who have less economic and military power than the settlers, become a minority group. Many European countries, including Belgium, France, Great Britain, Portugal, and Spain, established large colonial empires between the 1400's and the 1900's.

After establishing control over the minority, the dominant group may try to remove them from its territory. The dominant group may expel the minority, as white Americans did in the 1830's when they forced the Cherokee Indians to move from the Southeastern United States to reservations in what is now Oklahoma. Or the dominant group may attempt complete destruction of the minority. For example, American settlers gained control of North America by killing many of the native Indians. *Genocide* is a form of mass murder in which one organized group—usually a government—systematically kills members of another group. Between 1933 and 1945, the Nazis in Germany persecuted Jews on a regular basis. The Nazis murdered about 6 million Jews.

Relationships between groups

Most dominant and minority groups develop certain patterns in dealing with each other. These patterns include *racial or ethnic stratification, assimilation,* and *internal colonialism*. The dominant group usually controls how these patterns develop.

Racial or ethnic stratification occurs when the dominant group divides the society into classes along racial and cultural lines. Minority groups are given low social and economic positions. For example, many Irish, Italian, and black African immigrants to the United States were assigned such positions by British Americans and other groups that had settled earlier. For periods of varying length, minority groups that live under racial or ethnic stratification suffer segregation, discrimination, and poverty.

Assimilation may develop after the dominant and minority groups have lived together for some time. In this process, the dominant group accepts the minority group into society. Two types of assimilation take place, often at different speeds. In the process of *structural assimilation,* the minority group is partially or wholly admitted into the friendship groups and economic organizations of the dominant group. In the process of *cultural assimilation,* the minority group adopts much of the culture of the dominant group and may lose many of the cultural characteristics that had set it apart. For example, Scandinavian Americans gave up much of their ethnic heritage while undergoing cultural assimilation. Jews, on the other hand, preserved more of their own culture.

Internal colonialism occurs when minority groups achieve political and economic equality slowly or not at all. This pattern typically lasts for many years and in some cases for centuries. In the Western world, many nonwhite minorities have experienced a period of slavery or forced labor followed by many years of discrimination. In the United States, blacks, other non-European minorities, and women have suffered centuries of political, economic, and educational discrimination. Discrimination persists in the United States today, though laws prohibit much of it.

Results of minority status

Minority group members generally recognize that they belong to a less-favored group, and this realization affects their behavior. A sense of isolation and common suffering is a strong social glue that binds them together. Common cultural and physical traits also help unify the minority group. Identification with the minority may continue even after a minority group member is assimilated into the dominant group. For instance, a per-

son of Jewish descent may no longer practice the traditional Jewish religion and may become a member of the dominant group. Yet the person may continue to think of himself or herself primarily as a Jew.

Members of minority groups respond to domination in various ways. For example, some passively adopt the culture of the dominant group. Others try to achieve territorial separation. In the late 1800's, for example, some Jews reacting to discrimination in Europe began a movement called *Zionism* to establish a Jewish nation in Palestine. This movement resulted in the establishment of Israel. Attempts by small groups of black Americans to return to Africa in the 1700's and 1800's are another example of this response to domination. Some members of minority groups use various means to challenge domination. They challenge segregation laws in court, refuse to obey discriminatory laws, and, in some cases, resort to rioting and other forms of violence.

Minorities in the United States

The United States has become the home of many minority groups. These minorities include Hispanic Americans, African Americans, Jews, European immigrants, Asian Americans, and American Indians.

Hispanic Americans, also called *Latinos,* form the largest minority group in the United States. Hispanic Americans are primarily of Cuban, Mexican, and Puerto Rican ancestry. The United States has more than 35 million Hispanics, most of Mexican descent.

Cubans began to migrate to the United States in large numbers during the 1960's, after Cuba came under Communist control. Most have settled in Florida.

Mexicans became incorporated into the United States when the nation acquired what are now large parts of the West and Southwest from Mexico. Since the Mexican War (1846-1848), many Mexicans have migrated to the United States.

Puerto Ricans have migrated to the U.S. mainland in large numbers since World War II (1939-1945). Many have settled in New York City.

African Americans form the nation's second largest minority group. They make up 12 percent of the population, nearly 35 million people. Blacks were brought to America as slaves beginning in the early 1600's, and most blacks remained slaves until after the American Civil War (1861-1865). But even as they gradually gained legal freedom, most blacks could not assimilate into American life because of widespread discrimination. In the 1960's and 1970's, some blacks reacted to their exclusion from society by starting black nationalist or black power movements. These movements called for separation and the strengthening of black group-identity and political organization.

Jews have often fled to the United States from Europe and other areas to avoid persecution, only to meet continued discrimination. Today, there are about 6 million Jews in the United States. Many Jews have retained their religious beliefs and many traditional practices.

Other European immigrants who came to the United States often became minority groups. Most of these minorities were eventually assimilated into American society. Before the 1880's, most Europeans who came to the United States were from northern and western Europe. Beginning in the 1880's, most came from southern and eastern Europe. Most European immigrants have come from Austria-Hungary, Germany, Ireland, Italy, Poland, Russia, and the United Kingdom.

Asian Americans include Chinese, Filipino, Japanese, Korean, and Vietnamese groups. More than 10 million Asians live in the United States today.

Chinese have often been discriminated against. Some live in city neighborhoods called *Chinatowns.*

Japanese immigrants have often suffered the same injustices as the Chinese. During World War II, many Japanese Americans suffered violations of their constitutional rights. They were forced to leave their homes and businesses and to live in concentration camps in several Western states.

American Indians have suffered centuries of discrimination. Indians were driven from their homes by European settlers and were forced to live on reservations. About 2 ½ million Indians live in the United States today. Many now call themselves *Native Americans.*

Minority groups in other countries

Many nations have minority groups. European countries have often had minority nationality groups living within their boundaries. For example, before World War II, Germans lived in a part of Czechoslovakia called the Sudetenland.

Religious minorities have also lived in Europe. Today, Roman Catholics are a minority in Northern Ireland, and Jews form a minority in other parts of Europe.

In South Africa, many whites have discriminated against blacks and other nonwhites, though nonwhites make up most of the population. From 1948 to 1991, whites followed a government policy of *apartheid* (separateness). Under apartheid, almost all nonwhites were legally segregated from whites and faced official discrimination in education, employment, and many other areas. Blacks were not allowed to vote in national elections until 1994. Even after 1994, nonwhites faced unofficial segregation and discrimination in South Africa.

Many national minority groups lived in the Soviet Union. Under Soviet rule during World War II, some of these groups—the Volga Germans, Crimean Tatars, and Kalmuks—were expelled from their homelands, supposedly for disloyalty. Jews suffered discrimination under both czarist and Soviet rule. The Soviet Union broke apart in 1991. Many of its minority groups, including the Kazakhs, Moldovans, Ukrainians, and Uzbeks, formed independent nations. Today, ethnic tensions remain a threat to social stability in many of the former Soviet republics. Joe R. Feagin

Minos, *MY nuhs,* was a king of Crete in Greek mythology. He ordered Daedalus, a skilled artisan and inventor, to build the *Labyrinth.* This was a mazelike building in which Minos imprisoned a monster known as the Minotaur. Minos conquered much of Greece, including Athens. He forced the Athenians to send seven young men and seven young women at regular intervals as a sacrifice to the Minotaur. In time, Theseus, one of the intended victims, killed the Minotaur and eloped with Minos's daughter Ariadne. Minos imprisoned Daedalus for helping Theseus and Ariadne run away, but Daedalus escaped. Minos pursued Daedalus and finally found him in Sicily. According to one story, Daedalus killed Minos by scalding him in a specially constructed bathtub. After his death, Minos and his brother Rhad-amanthus became judges in the underworld. Justin M. Glenn

See also **Theseus; Minotaur; Daedalus; Hades.**

Minotaur, *MIHN uh tawr,* in Greek mythology, was a monster that was half man and half bull. It is usually shown with the head of a bull and body of a man. The Minotaur was the offspring of a bull and Pasiphae, the wife of King Minos of Crete. Minos kept the Minotaur in the Labyrinth, a mazelike building from which no one could escape. Minos sacrificed seven Athenian youths and seven Athenian maidens to the Minotaur each year. Theseus of Athens finally killed the Minotaur and escaped from the Labyrinth by following a thread given to him by Minos's daughter, Ariadne. See **Theseus.**

A palace excavated during the 1900's at Knossos in Crete has so many passageways that it resembles the legendary Labyrinth. Paintings found there show bulls and bull-baiting games. William F. Hansen

Theseus and the Minotaur (1848), a bronze statue by Antoine Louis Barye; the Walters Art Gallery, Baltimore

The Minotaur, in Greek mythology, was half man and half bull. Theseus, a Greek hero, killed it on Crete.

Minsk (pop. 1,613,000) is the capital of Belarus. In 1991, it became the headquarters of the Commonwealth of Independent States, a loose confederation of nations that were formerly republics of the Soviet Union. Minsk lies on the Svisloch River. For location, see **Belarus** (map).

Factories in Minsk produce ball bearings, machine tools, peat-digging machines, radios, trucks, and tractors. Woodworkers in the city produce prefabricated houses and furniture. Minsk is the home of the Belarusian state university, medical and polytechnic schools, an academy of sciences, a state museum, and an opera and ballet theater.

Minsk suffered heavy damage during the fighting in World War II (1939-1945). After the war, Minsk expanded greatly with the construction of many new factories and new housing for the workers. Theodore Shabad

Minstrel is a term most broadly used to refer to professional entertainers who flourished in Europe during the Middle Ages. Minstrels were chiefly singers and musicians, but many were also storytellers, jugglers,

Detail of a German illuminated manuscript (early 1300's) (Granger Collection)

A German minstrel called a *minnesinger* sang love poetry. Minnesingers were popular during the Middle Ages.

clowns, and tumblers. These wandering performers were known by different names in different countries. They were called *troubadours* and *jongleurs* in France, and *minnesingers* in Germany. They were known as *skalds* in Scandinavia and *bards* in Ireland. The early English minstrel was called a *scop.* The name *minstrel* was used for the later poet-musicians of England.

Some minstrels belonged to the households of kings and nobles. Some traveled about and gave entertainments at castles or villages along their way. The minstrels often made up their own songs and stories as they entertained. But they also repeated ballads and folk tales of the time, thus helping to preserve them. The minstrels began to die out by the late 1400's. The printing press eventually replaced the storytellers. Don B. Wilmeth

Minstrel show was the first uniquely American form of show business. Minstrel shows began in the 1840's and reached their peak of popularity about 1870, though they existed until about 1900. Most minstrel shows were performed by white entertainers who blackened their

A minstrel show traditionally featured white performers in blackface. The show opened with the entertainers grouped in a semicircle. The men on each end, called Mr. Tambo and Mr. Bones, exchanged jokes with the interlocutor, wearing white gloves in the center.

Culver Pictures

faces to impersonate blacks. A few black minstrel companies also toured the United States. Minstrel shows reinforced negative images of blacks that lasted long after the shows had disappeared.

In 1846, the American showman E. P. Christy organized the Christy Minstrels, the first important minstrel company. The American composer Stephen Foster wrote many of his best-known songs for the Christy Minstrels (see **Foster, Stephen Collins**). Christy developed the distinctive three-part format for the minstrel show. During the first part, the whole company sat in a semicircle on stage while the master of ceremonies, called the *interlocutor,* and the star performers, named Mr. Bones and Mr. Tambo, exchanged jokes. This part was followed by the *olio,* a variety section that featured comedy routines, sentimental songs, and dances. The third part of the minstrel show was a one-act skit.

Minstrel companies performed in permanent minstrel theaters in almost every major city in the United States, especially in the Northeast. Companies also toured smaller cities and towns. The unsophisticated and fun-filled shows especially appealed to less educated audiences. Don B. Wilmeth

Mint is a place where coins are made. In the United States and most other countries, only the government may *mint* (manufacture) coins. American mints are supervised by the United States Mint, a division of the Department of the Treasury. Mints now operate in Denver, Philadelphia, San Francisco, and West Point, New York. They make only coins. The Bureau of Engraving and Printing in Washington, D.C., makes paper money.

United States mints make half dollars, quarters, dimes, nickels, and cents for general circulation. They also make commemorative coins for special occasions and gold and silver bullion coins for investors. For a description of how U.S. coins are minted, see **Money** (Minting coins).

Historians believe the world's first mint was founded during the 600's B.C. in Lydia, now a part of Turkey. Ancient Mediterranean civilizations, including Greece and Rome, used coins in commerce. The use of coins gradually spread throughout Europe and Asia.

The first mint in the United States was established in Boston in 1652. It produced coins under the authority of the General Court of the Massachusetts Bay Colony. The Articles of Confederation of 1781 gave both the U.S. Congress and the individual states authority to mint money and regulate its value. The first federal mint opened in Philadelphia in 1792 and is still in operation. Other federal mints have operated in Carson City, Nevada; Charlotte, North Carolina; Dahlonega, Georgia; Denver; New Orleans; and San Francisco.

Coins were minted in England before the coming of the Romans in A.D. 43. The present British Royal Mint has operated in London since 1810. The Canadian mint was established in Ottawa in 1870 as a branch of the British Royal Mint. It became a part of the Canadian Department of Finance in 1931. R. G. Doty

Mint is the name of a large family of plants that grow mostly in temperate regions. There are about 3,500 species of mints. Many are highly fragrant. Their leaves are dotted with small glands that contain aromatic oils. The oils are released when the leaves are crushed.

The leaves of all mint plants grow in pairs on opposite sides of the stem, which in most species is distinctly square. Most mint plants have small, white, bluish, or pinkish flowers. In some species, such as lavender and peppermint, the flowers grow on spikes at the end of the stem. Mint plants usually bear small, roundish fruit that divides into four nutlets when mature.

WORLD BOOK illustration by John D. Dawson

Mint

Mint plants are particularly abundant in the countries that border the Mediterranean Sea. Both the leaves and the oil of mints are used as herbs for flavoring in cooking. The leaves may be used either fresh or dried. Popular cooking mints include marjoram, rosemary, and sage. Such mints as white horehound and peppermint add a cool, sharp flavor to candies. Mints also are used in some medicines and perfumes. Donna M. Eggers Ware

Scientific classification. Mints make up the mint family, Lamiaceae or Labiatae.

Minto, Earl of (1845-1914), was a British colonial administrator who served as governor general of Canada from 1898 to 1904. As governor general, he supported sending Canadian volunteer forces to southern Africa to aid British troops in the Boer War (1899-1902). French-speaking Canadians opposed Canadian participation in

foreign wars and protested the move. English-speaking Canadians approved it. As a result, the French-speaking group and the English-speaking group became more divided on Canada's role in the British Empire. Minto also promoted land conservation and the creation of the Public Archives of Canada.

The Earl of Minto was born in London. His given and family name was Gilbert John Murray Kynynmond Elliot. In 1891, he inherited the family estate near Hawick, Scotland, succeeding his father as Earl of Minto. Minto was viceroy of India from 1905 to 1910. He helped bring about reforms that enlarged government councils to include elected Indians for the first time. Jacques Monet

Minuet was the leading couple dance of the European royal courts and high society from the late 1600's to the late 1700's. Most minuets are composed almost entirely of the basic minuet step, which takes two measures of moderately lively $\frac{3}{4}$ time. The dancers move along a prescribed route in the form of an S or Z. They engage in a set series of encounters, first taking right hands, then left hands, and finally both hands. *Minuet* is also the term for music that accompanies the dance.

The minuet was first developed in the court of King Louis XIV of France in the late 1650's and early 1660's. The dance subsequently gained favor across Europe as an ornament of well-bred accomplishment. Minuets appear in many ballets and operas of the late 1600's to late 1700's. From the late 1600's to the early 1800's, the minuet became a standard movement in musical forms with two or more movements, such as the sonata, string quartet, and symphony. Patricia W. Rader

Minuit, *MIHN yoo iht,* **Peter** (1580-1638), was a Dutch colonial governor who bought Manhattan Island from the Indians in 1626. He paid with trinkets costing 60 Dutch guilders, or about $24 (see **Manhattan Island**). This purchase legalized the occupation of the island by the Dutch West India Company. Minuit made New Amsterdam, a settlement on the southern half of Manhattan Island, the center of the company's activities. Minuit supervised the building of Fort Amsterdam. The fort was designed primarily to protect the Hudson River mouth, a vital highway for the fur trade. New Amsterdam became an important trade center under the Dutch. The English later renamed the colony New York.

The Dutch West India Company recalled Minuit in 1631 for granting too many privileges to the *patroons* (wealthy landowners). Later, the Swedish government asked him to lead its first expedition to America, and he returned to America in 1638. He built Fort Christina, named after the queen of Sweden, at what is now Wilmington, Delaware. Shortly thereafter, he drowned at sea.

Minuit was born in Wesel, Germany, but moved to the Netherlands as a young man. In 1626, he became the governor and director-general of New Netherland, the Dutch colony in North America. Oliver A. Rink

Minute is a unit that is used to measure both time and angles. In time, 60 minutes make up one hour. Each minute is divided into 60 seconds. Because an hour is $\frac{1}{24}$ of a day, a minute is $\frac{1}{1,440}$ of a day. In measuring angles, 60 minutes make up one degree. A circle is divided into 360 degrees, and so one minute is $\frac{1}{21,600}$ of a circle. Each minute of an angle is divided into 60 seconds.

The minute in time is an exact measurement, which means exactly so much time. The minute of an angle is an exact portion of a circle, and is independent of the size of the circle. But if the angle is denoted by a linear measurement along the circumference, the distance of a minute depends on the circle's diameter. For example, a minute on a baseball measures only a small fraction of an inch. On the earth's surface a minute is one nautical mile, about 6,076 feet, or 1,852 meters (see **Mile**).

The circle was first divided into 360 degrees by ancient civilizations, either the Babylonians or the Egyptians. The Babylonians figured everything in units, 10's, and 60's instead of 10's and 100's, as we do. The degree was divided into 60 parts and each of these parts was divided into 60 parts. The Romans called the first divisions the *partes minutae primae,* or "first small parts." The second division they called the *partes minutae secundae,* or "second small parts." These terms were finally shortened to *minute* and *second.* James Jespersen

See also **Degree; Hour; Second.**

Minutemen were volunteer soldiers who fought for the American Colonies against Britain at the beginning of the Revolutionary War in America (1775-1783). Just before the war, they were trained and organized into military companies. They were called *minutemen* because they were ready to fight "at a minute's notice."

When the Massachusetts militia was reorganized in 1774, the Provincial Congress provided that one-third of all the new regiments were to be made up of minutemen. The most famous action of the minutemen occurred on April 19, 1775, at Lexington and Concord, where they fought side by side with the militia. Minutemen groups disappeared when regular armies were formed. James H. Hutson

Miquelon. See **Saint-Pierre and Miquelon.**

Mir was the longest-lasting space station ever built. The station, which was built by the Soviet Union, consisted of several separately launched spacecraft or modules. The first module went into orbit in 1986, and the space station was destroyed in 2001. *Mir* is a Russian word for *peace.*

The Soviet Union began to assemble Mir during the years of the "space race" competition between the Soviet Union and the United States. The Soviets intended to operate Mir for five years. But the Soviet Union collapsed in 1991, and what became the Russian space industry went into decline. As a result, the Russians chose to extend Mir's lifetime, rather than build another space station.

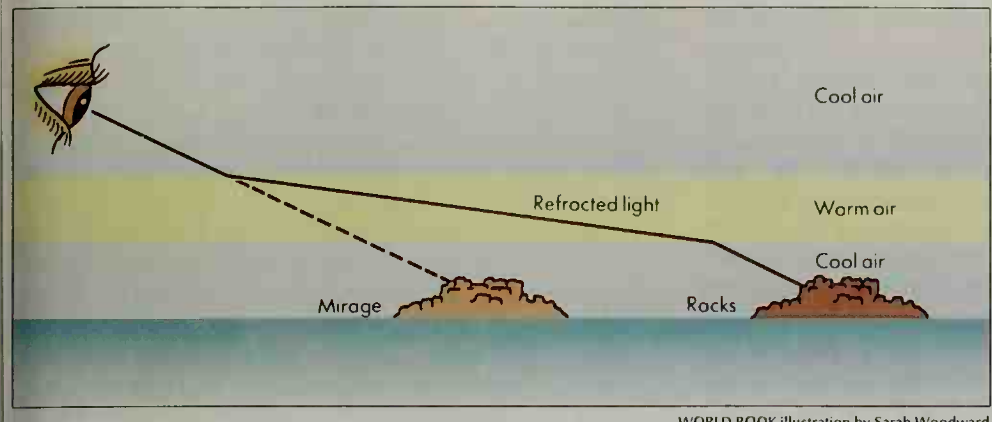
Equipment breakdowns and human errors led to several accidents. In an especially dangerous accident in June 1997, a Progress ship collided with a module known as Spektr. The crash opened a small hole in the module, which began to leak air. The crew quickly sealed off Spektr.

Due to budget restrictions, Russia ended the Mir project in March 2001. One reason for the restrictions was Russia's role in the construction of the International Space Station, which began in 1998. Russia destroyed Mir by guiding it into the atmosphere. Much of the station burned, and the remainder fell into the Pacific Ocean.

NASA

The Mir space station was made up of several modules that were launched separately, then permanently docked in space. This picture shows not only the permanent modules but also the Progress and Soyuz-TM spacecraft that traveled between the space station and Earth.

The first part of Mir to go into orbit was the Core Module, or Base Block. This module was a modified version of Salyut space stations that the Soviets orbited from 1971 to 1982. The module had docking ports at both ends. Docked at one end was the Kvant 1 laboratory and life-support module, which was launched in 1987. Attached at the other end was the Transfer Node, a large, hollow ball with five docking ports and a door to the Core Module.



The five ports faced different directions, like the sides of a cube. The port opposite the Core Module was available for Soyuz-TM vehicles, which transported crew members. Docked at the other four ports were (1) Kvant 2, a lab with a large air lock and life-support facilities, launched in 1989; (2) Kristall, launched in 1990 as a docking module for a planned Soviet shuttle; (3) Spektr, a science laboratory, launched in 1995; and (4) the Priroda earth observatory, launched in 1996. In 1995, the U.S. shuttle Atlantis left a docking module attached to Kristall for future shuttle flights. An assembly of the permanent modules, a Soyuz-TM, and a Progress supply ship measured 107 feet (33 meters) in length. James Oberg

Mirabeau, *MIHR uh boh* or *mee ra BOH,* **Comte de** (1749-1791), was a French statesman, orator, and leader of the French Revolution (1789-1799). His powerful, eloquent speeches made him the most forceful enemy of the French royal court. Mirabeau wanted the government to consist of both a monarch and an elected assembly, like the constitutional monarchy of Britain. His political beliefs were sincere, but he was always in debt and had a disgraceful personal life. As a result, neither King Louis XVI nor the revolutionaries fully trusted him.

Mirabeau was born in Bignon. His father was a nobleman. Mirabeau's given and family name was Honoré Gabriel Victor de Riqueti. In 1767, he became a cavalry officer in the French army. Mirabeau left the army after serving in Corsica in 1769. From 1774 to 1780, he was imprisoned several times for debt and other offenses.

In 1780, Mirabeau moved to the Netherlands. There, he began writing pamphlets attacking the despotism of the French monarchy. These writings made him famous among the middle class throughout Europe. By 1788, Mirabeau had returned to France. In 1789, he was elected to represent Aix-en-Provence in a body called the Estates-General (see Estates-General). Despite his noble background, Mirabeau was chosen as a delegate of the

A mirage can be caused by light rays bending when they pass through substances of different densities. In the drawing at the left, light rays from the distant rocks bend as they pass from the cool, heavy air near the surface to the upper warm, light air. This produces a mirage that makes the rocks appear closer than they are.

WORLD BOOK illustration by Sarah Woodward

third estate, which included peasants, working people of the cities, and the middle class. In June 1789, the delegates of the third estate declared themselves the National Assembly of France. They took an oath not to disband until they had written a constitution for France. On June 23, a chief aide of Louis XVI ordered the deputies to leave their meeting place at Versailles. Mirabeau thundered, "Go and tell your master that we are here by the will of the people and that we shall not budge save at the point of a bayonet." The deputies stayed.

Mirabeau was a founder and an active member of the Jacobin Club, a powerful group of revolutionary leaders (see **Jacobins**). In 1791, he was elected president of the National Assembly. Mirabeau urged the king to accept the many reforms adopted by the Assembly and to take his place as a constitutional monarch. The royal family rejected his wise advice. Mirabeau died after a brief illness and was buried as a national hero. Isser Woloch

Miracle is an event that cannot be explained through the known laws of nature. Miracles are generally associated with religion, but any occurrence can be called a miracle if it has no natural explanation.

The major figures in a religion are often credited with performing miracles. These figures include Jesus Christ in Christianity, Moses and the prophets in Judaism, Muhammad in Islam, and various gods in Hinduism. Many religions also teach that lesser holy figures, such as saints and rabbis, may also perform miracles. People may make pilgrimages to certain sacred places and objects to ask for a miracle. For example, Roman Catholic pilgrims travel to the shrine at Lourdes, France. There they pray to the Virgin Mary to plead with God on their behalf for miraculous cures.

Devout members of a religion believe in miracles and consider them a divine sign. Others have an equally firm belief that there is no such thing as a true miracle. They feel that all so-called miracles can be explained through scientific or psychological knowledge. Jill Raitt

See also **Jesus Christ** (The miracles); **Shrine; Saint; Lourdes; Ba'al Shem Tov.**

Miracle play is a form of religious drama which was popular in the Middle Ages. It was based on the lives of the saints. At first, the plays were presented as a part of Roman Catholic Church services. But, like the mystery plays out of which they developed, they lost the approval of the church. The plays were driven from the church to the streets or public squares. In England, trade guild members performed these plays on feast days. Miracle plays have been revived from time to time, but interest in this type of drama has become chiefly literary. See **Drama** (Medieval drama). Albert Wertheim

Mirage, *muh RAHZH,* is a type of optical illusion. A mirage may occur when a person is driving and sees what seems to be a pool of water lying on a hot paved road ahead. But when the person reaches the spot, the water has disappeared or has seemingly moved farther down the road. Mirages may include distant objects that seem to be closer than they truly are. Other objects, such as a mountain or a ship, may seem to float in the sky. Mirages can be seen in deserts, at sea, or in the Arctic.

The bending of light rays as they pass through air with different temperatures causes a mirage. This bending motion is called *refraction* (see **Refraction**). The most common type of mirage is the *oasis mirage.* Desert travelers sometimes experience it when they see a distant pool of water that appears to be an oasis. But when they reach the spot, they find only dry sand.

An oasis mirage can be produced when light from the sun heats the ground and the air just above it. A ray of light from the sky passes first through the cooler air high above the ground and then into the warmer or hotter air near the ground. The speed of the light increases as it enters the warmer air because fewer air molecules get in the way of the light. The gradual change in the speed of the light forces the ray to change its direction. The ray bends upward just before it reaches the ground.

A person cannot see the path the ray takes. Since the ray is traveling upward when the person sees it, the person thinks that the ray came from a spot on the ground. Hot air above the ground mixes rapidly with other layers of air heated by the sun. As the ray travels through these layers, the hot air causes the ray to ripple or "wiggle." The light of an oasis mirage is blue because it comes from the sky. Therefore, the person concludes that this blue spot must be a pool of water that has small waves. But what the person really sees is part of the sky. The rays that produce mirages are real. Therefore, mirages can be photographed.

Another type of mirage is known as the *Fata Morgana.* Fata Morganas are the most beautiful of all mirages. A Fata Morgana occurs when a layer of hot air traps rays of light coming from the distant objects. Objects such as rocks or chunks of ice appear to be towers of a fairy-tale castle. Jearl Walker

Miramichi River, *MIHR uh muh SHEE,* is an important waterway in New Brunswick. Its main branches are the Northwest Miramichi River and the Southwest Miramichi River. These two branches meet southwest of New-

castle and form the Miramichi River. The Miramichi, a famous salmon stream, flows northeast and empties into the Gulf of St. Lawrence through Miramichi Bay. Large ships can sail up the river to Newcastle, about 30 miles (48 kilometers) from the river's mouth. T. W. Acheson

Miranda, *mee RAHN dah,* **Francisco de** (1750-1816), was a Venezuelan patriot, professional soldier, and gifted statesman. He took the lead in declaring Venezuela's independence from Spain in 1811 though the country did not gain true independence until after his death. Unsuccessful as Venezuela's dictator, Miranda surrendered his forces to the supporters of the Spanish king. His former subordinates, including Simón Bolívar, handed him over to the Spanish. Miranda died in a Spanish dungeon. He was born in Caracas. Michael L. Conniff

Miranda v. Arizona, *mih RAN duh,* was a case in which the Supreme Court of the United States limited the power of police to question suspects. The court ruled in 1966 that nothing arrested persons say can be used against them in their trial unless they have been told they have certain rights. For example, suspects must be told they have the right to remain silent, and that anything they say can be held against them. They also must be told they can have a lawyer present during questioning, and, if they cannot afford one, the court will appoint one. If a suspect requests an attorney, the questioning must cease until an attorney is present.

The court's decision reversed the conviction of Ernesto A. Miranda, a Phoenix warehouse worker, on charges of kidnapping and rape. He had confessed, and his confession was used as evidence against him. But he had not been told of his right to remain silent and had been denied the right to consult a lawyer.

The Supreme Court based its decision on the Fifth and Sixth amendments to the United States Constitution. The Fifth Amendment to the Constitution protects persons from being forced to testify against themselves. The Sixth Amendment to the Constitution guarantees a defendant's right to a lawyer.

Several later Supreme Court decisions limited the scope of the ruling in *Miranda v. Arizona.* In 1971, for example, the court ruled that a confession obtained in violation of the *Miranda* decision can be used at a trial to prove the defendant is lying. In 2000, however, the court upheld the main rulings in the original *Miranda* decision. Stanley I. Kutler

See also **Escobedo v. Illinois.**

Miró, *mee ROH,* **Joan,** *hoh AHN* (1893-1983), was a Spanish painter who developed an imaginative and extremely personal style. His highly abstract forms suggest real people and animals as well as fantastic creatures and objects. Many of Miró's paintings contain a story or scene disguised by the apparent abstractness of the shapes and colors.

Miró developed his characteristic style during the 1920's and early 1930's. His mature work portrays a world of fantasy, which he pictured in brightly colored shapes and lively expressive lines. A work from this period, *Carnival of Harlequin,* appears in the **Painting** article. Miró also worked in other art forms, including ceramics, sculpture, and *lithography,* a type of printmaking.

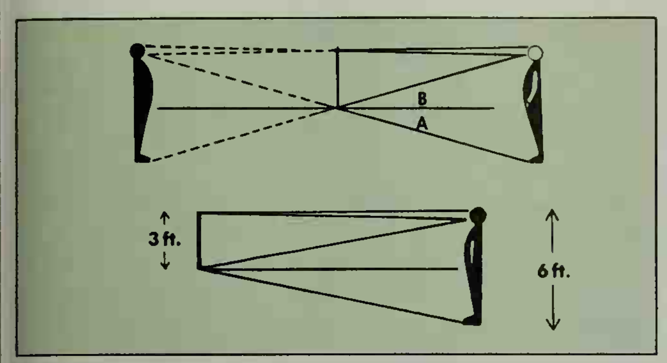
Miró was born in Montroig, Spain, near Barcelona. In 1919 he went to Paris, where he helped establish the surrealism movement in the 1920's. Pamela A. Ivinski

Mirror is any smooth surface that reflects most of the light striking it. Only a small fraction of the light is absorbed by a mirror. In addition to being nonabsorbent, a surface must be smooth to about $\frac{1}{25,000}$ inch (0.0001 centimeter) to reflect sharp images. Some rough surfaces reflect light, but they scatter it in all directions so that no image is formed.

Most mirrors are made by putting a thin layer of silver or aluminum onto a sheet of high-quality glass. The glass supports the metallic layer and protects its shiny surface. Many mirrors in scientific instruments have the metal coating in front of the glass. A polished sheet of metal—without glass—can also serve as a mirror.

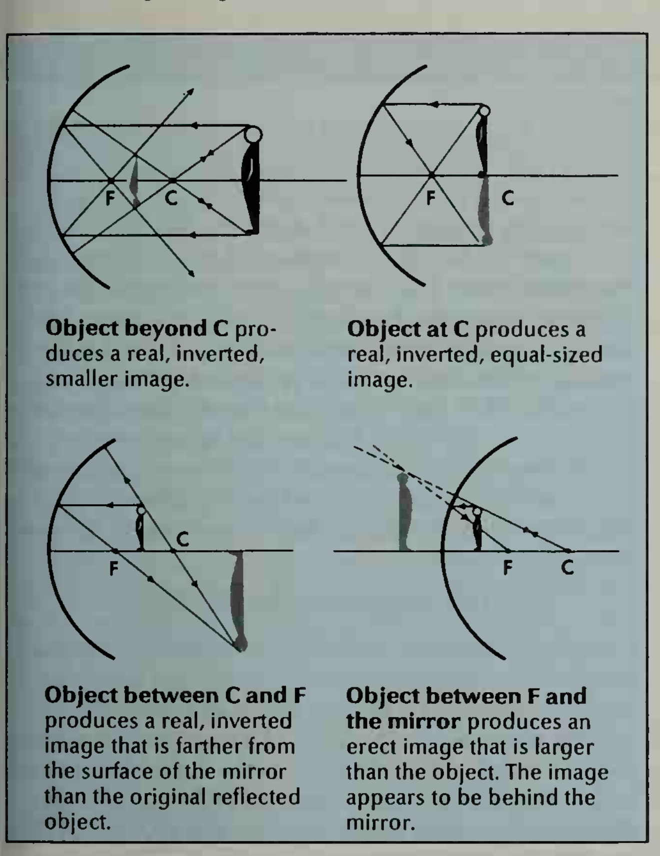
Images reflected by a mirror vary according to the mirror's shape. There are three principal kinds of mirrors: (1) plane mirrors, (2) convex mirrors, and (3) concave mirrors.

Plane mirrors have a flat surface. Most looking glasses are plane mirrors. A line perpendicular to a plane mirror at any point of reflection is called the *normal.* Light strikes the mirror at some angle to the normal, and this angle is known as the *angle of incidence.* Light is reflected back at an equal angle on the other side of the normal. This angle is called the *angle of reflection.* The two angles are always equal.

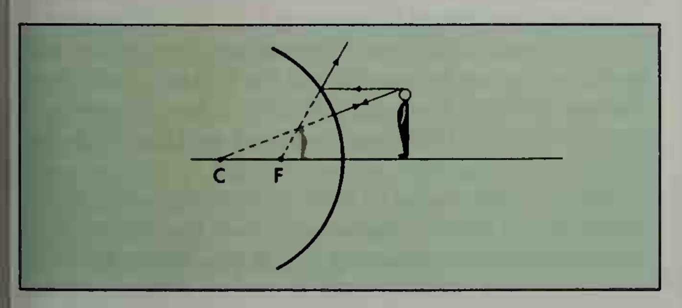


An image in a plane mirror is a *virtual image,* one that appears to be behind the mirror. It is *erect* (correct end up), but reversed from left to right. The image is the same size as the object it reflects and appears to be equidistant from the mirror.

Convex mirrors are curved like part of the outer surface of a sphere. When a convex mirror is illuminated by



Women and Birds in the Night (1934), an oil painting on canvas; Yale University Art Gallery, Bequest of Kay Sage Tanguy



A painting by Joan Miró shows the simple forms, playful images, and sense of fantasy that are typical of the artist's style.

In a plane mirror, the image is at the mirror, but appears to be as far beyond it as the object is in front of it. In a mirror, *top,* the angle of incidence (A) equals the angle of reflection (B). Because of this, a mirror must be at least half the height of a person to reflect a full-length image, *bottom.*

In a concave mirror, *above,* such as those used for shaving, the position and size of the *image* (in gray) depend on the position of the *object* (in black) in relation to the mirror's *center of focus* (F) and *center of curvature* (C). The position of the object also determines whether the image is *real* (formed in front of the mirror) or *virtual* (appears formed behind the mirror).

A convex mirror, as pictured in the diagram above, produces an upright image that is much smaller than the object. The image formed appears to be behind the mirror.

parallel rays of light, the reflected light seems to come from a point behind the mirror called the *focus.* The focus is halfway between the mirror and the mirror's *center of curvature,* the center of the sphere of which the mirror is a part.

A convex mirror forms virtual images that are erect and *demagnified*—that is, smaller than the object being reflected. Many automobiles have a convex rear-view mirror, which provides a wider field of vision than a plane mirror. But the reflected objects appear farther away than they are because they are demagnified.

Concave mirrors are hollow and curved like part of the inner surface of a sphere. The focus and center of curvature are both in front of the mirror. The focus is a *real focus* because parallel light rays striking the mirror meet at this point when they are reflected. Solar ovens use concave mirrors to focus sunlight.

An image produced by a concave mirror may be either a virtual image or a *real image.* A real image, unlike a virtual one, is formed in front of the mirror and is produced by the actual intersecting of reflected light rays. The properties of an image formed by a concave mirror are determined by the position of the object being reflected. For an object between the mirror and its focus, the image will be virtual, erect, and magnified. Objects beyond the focus, however, produce real images. They may be erect or inverted, and magnified or demagnified, depending on the position of the object.

Concave mirrors include shaving mirrors, make-up mirrors, and mirrors in reflecting telescopes. Concave and convex mirrors both produce somewhat distorted images. Sandra M. Faber

MIRV. See **Guided missile** (The warhead; diagram).

Miscarriage, also called *spontaneous abortion,* is the accidental or natural ending of a pregnancy before a baby can live outside its mother's body. Studies indicate that 15 to 20 percent of all diagnosed pregnancies end in miscarriage. But the risk of miscarriage is highest during the first two weeks following *conception* (fertilization), a time at which most women do not even know they are pregnant. Thus, many physicians believe the overall rate of miscarriage, including undiagnosed pregnancies, may actually be as high as 50 percent.

Up to 60 percent of all miscarriages occur because of defects in the embryo's *chromosomes.* Chromosomes are tiny, threadlike structures that carry genes. In most miscarriages involving defective chromosomes, the embryo cannot develop normally. A miscarriage may also occur if *progesterone,* a hormone necessary to maintain pregnancy, is not present in sufficient amounts. Some women miscarry because the *uterus,* the organ in which the offspring develops, cannot withstand the pressures of the growing fetus. Some *chronic* (long-term) diseases, such as diabetes and kidney disease, also are linked to miscarriages. Pregnant women with such diseases require close medical attention. Lois Kazmier Halstead

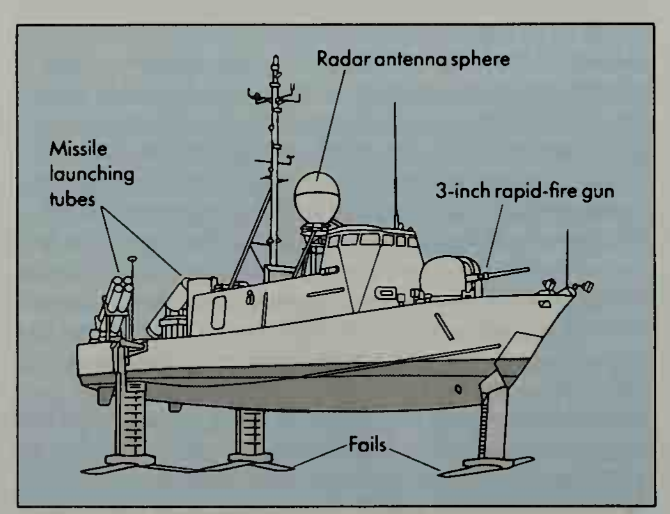
Misdemeanor is any violation of the law which is less serious than a felony. Assault and battery, the theft of a small sum of money, and other such acts against public safety and welfare, are misdemeanors. So are most traffic offenses. Not all courts draw the same line between misdemeanors and felonies. A felony in one court may

be a misdemeanor in another. People guilty of misdemeanors are usually fined or given a short jail sentence. See also Felony. George T. Felkenes

Miskolc, *MIHSH kawlts* (pop. 189,655), is a city in Hungary. Miskolc, a busy commercial center, is located on the Sajó River in the northeast industrial region of Hungary. For the location of Miskolc, see Hungary (political map).

During the 1300's, Miskolc developed as a busy market town and center of the Hungarian wine trade. Handicrafts industries flourished there in the 1700's. Iron smelting and engineering industries developed during the 1800's and remain important. Other industries produce cement, furniture, paper, and textiles.

The city's Herman Ottó Museum features noted archaeological exhibits. The University of Miskolc provides training in the arts and social sciences, economics, law, and various fields of engineering. Popular health spas and a resort hotel are located in nearby Lillafüred, west of Miskolc. Thomas Sakmyster



Missile, Guided. See Guided missile.

Missile boat is a small, fast warship that can fire guided missiles. It is used by navies to patrol and defend narrow seas and coastal waters.

Missile boats measure from about 83 to 200 feet (25 to 61 meters) long and can travel up to 40 *knots* (nautical miles per hour) or faster. They have diesel or gas turbine engines, or both. Missile boats carry from two to eight missiles. The missiles can reach enemy ships up to about 60 miles (100 kilometers) away. In addition, missile boats have one or more guns for use against aircraft and small ships. These guns may be of up to 3-inch caliber.

Many missile boats are *hydrofoils* (see Hydrofoil). At high speeds, their hulls are raised above the water by *foils,* wing-shaped structures below the surface. These craft are powered by diesel engines when their hulls are in the water, and by gas turbines when they are above the water on their foils.

The first missile boats were built by the Soviet Navy and went to sea in 1958. The most famous Soviet missile boat classes, the *Osa* and the *Komar,* have been used by many navies. In 1967, the Egyptian Navy used Komar class boats to sink an Israeli destroyer. The Egyptian boats were in their own harbor when they fired four missiles at the destroyer, which was 12 ½ miles (20 kilometers) off the coast. The United States and other nations began to develop missile boats following this and other sinkings by Soviet-built craft. The first U.S. Navy missile boat, the *Pegasus,* was completed in 1976.
Norman Polmar

WORLD BOOK illustration by George Suyeoka

A missile boat of the U.S. Navy, *shown here,* can skim over the water on foils. It can fire up to eight missiles at enemy ships.

Mission life in America thrived for more than 250 years in a belt of North America known as the Spanish Borderlands. From the 1560's to the 1820's, Spanish missionaries established themselves among the Indians in this region, which covered a vast area north of Spain's colonial empire in Latin America. Missions developed in what are now Georgia, Florida, Texas, New Mexico, Arizona, and California. French missions arose in the Great Lakes area, and there were some villages of Indian converts to Christianity in New England. Christian missions also were later established on United States Indian reservations. However, this article focuses on the development, the daily life, and the heritage of the Spanish missions.

In the 50 years after the arrival of Christopher Columbus in 1492, Spain claimed most of the New World. The pope, as head of the Roman Catholic Church, granted the Spanish monarchs great authority over the church in the Americas. As a result, missions became agencies of the government. The Spanish government paid the missionaries' expenses, hoping they could persuade the Indians to become loyal Spanish citizens, as well as Roman Catholics. Spain's two chief interests—the protection of its empire and the conversion of the Indians—usually determined where and when missions would be established. Spanish soldiers and missionaries came to Florida from Cuba and the Caribbean. Other missionaries in the Spanish Borderlands came by way of *New Spain* (Mexico).

Development of the missions

Eastern missions. In the Roman Catholic Church, missionary work had long been a specialty of certain groups known as *orders.* Members of one order, the Society of Jesus (Jesuits), labored and died among the Indians of the humid south Atlantic coast between 1566 and 1572. Most of the missionaries in the Spanish Borderlands, however, were members of the Order of Friars Minor (Franciscans).

Franciscans operated missions in what are now Florida and Georgia for almost 200 years. By 1655, there were 38 missions in the area. Because the Indians moved around a great deal to hunt, fish, and wage war, the missions often changed locations. At times, European diseases caused many deaths among the Indians. After the founding of Charleston, S.C., in 1670, English settlers began to lure surviving Indians away with trade goods and guns. Some attacked the Indians, often enslaving or killing them. By 1708, only a few missions were left, and in 1763, Spain surrendered Florida to the United Kingdom.

Western missions. In 1598, Spain established a colony in the New Mexico area, where Pueblo Indians had an advanced civilization. The group that settled there included Franciscan missionaries, who sought to control the colony in the 1600's. Churches were built in about 50 Pueblo towns. In the early 1600's, the friars claimed to have about 35,000 mission Indians.

Detail of a drawing by William Alexander, Newberry Library, Chicago

Spanish missions in America thrived in parts of the South and West from the 1500's to the 1800's. They introduced Christianity to thousands of American Indians. This drawing, made in 1792, shows Mission San Carlos Borromeo de Carmelo, near what is now Carmel, Calif.

Indians sometimes challenged European colonization because it disrupted their former ways of life. The bloodiest Indian uprising took place in 1680, when the Pueblo Indians drove the outnumbered Spaniards from the New Mexico colony and killed over 400 of them (see **Indian wars** [The Pueblo revolt]). The surviving Spaniards retreated to the El Paso, Tex., area. Twelve years later, they recolonized in New Mexico.

In the 1680's, Spaniards began occupying parts of present-day Texas. Spain relied on missions, *presidios* (forts), and other settlements to prevent the advance of French explorers and traders into the Texas area. Spain also hoped to befriend the powerful Indian tribes of this region, including the Apaches and Comanches. By the mid-1700's, there were a few widely scattered clusters of missions that had survived Indian invasions. Some of the most memorable were the adobe and stone missions in the San Antonio area. These missions were known as the "Alamo chain."

From 1691 to 1711, Eusebio Francisco Kino, a Jesuit missionary, led many expeditions in the area that is now Arizona. These expeditions created a demand for Spanish missionaries and goods throughout the region. The Franciscans replaced the Jesuits in the Arizona region in 1768. They rebuilt San Xavier del Bac, which Kino had founded near Tucson in 1700. The Franciscans remained in the region until the late 1820's. See **Kino, Eusebio Francisco**.

The Spanish settlement of California began in 1769. That year, soldier-settlers and missionaries took possession of the area that became the city of San Diego. The Franciscan Junípero Serra founded the first California mission, known as San Diego de Alcalá, on this site. Serra went on to found 8 more of California's 21 missions before his death in 1784. These missions became home to thousands of Indians. Some of the California missions developed into major agricultural and manufacturing centers.

In 1833 and 1834, the Mexican government seized and redistributed properties that belonged to the missions. This action brought an end to the active involvement of missions in the Spanish Borderlands. See **Serra, Junípero**.

Life at the missions

The Spanish missions fed, clothed, and often housed the Indians who entered them. In return, the Indians agreed to take instruction in Christianity, to observe Spanish customs, and to work for the mission.

Many Spanish missions included dining areas, schools, storerooms, and workshops, as well as living quarters and a church. In most cases, these structures were built of adobe or stone and arranged around a square courtyard. All the missions had farms, and many operated ranches. The California missions became especially productive. In 1834, Indians there herded a total of 396,000 cattle; 62,000 horses; and 321,000 sheep, goats, and pigs. They also harvested 123,000 bushels of grain.

In the mornings, mission Indians attended religious services and received instruction in Catholicism. Some of them learned to read and write in Spanish. During the rest of the day, they worked, usually on the farms. Some Indians learned carpentry, metalworking, and other skills from the missionaries and from outside workers hired to supervise construction of the churches and other mission buildings.

At first, many Indians welcomed the benefits of a more reliable and varied food supply, protection from enemies, and the rich ceremonies of Roman Catholicism. Later, various problems developed. Many Indians objected to the highly structured mission routine and to the fact that they were forbidden to leave without permission. They resented the missionaries' attacks on their former religions and traditions, and they feared the diseases that killed many of their family members. Some of the Indians fled. Others rebelled, often destroying churches and killing missionaries.

Missionaries were able to keep many Indians under mission discipline for several generations. When the missionaries left or the missions closed, however, some Indians returned to their former way of life. Discrimination and a lack of education prevented even skilled Indi-

Mission San José was established in San Antonio in 1720. Its many graceful carvings, which attract thousands of visitors yearly, are reminders of Spanish rule in America.

ans from getting good jobs and receiving equal rights among whites.

A visitor's guide

A number of Spanish missions in the United States have been maintained through the years, restored, or rebuilt. Following are brief descriptions of some of these Spanish missions.

La Purísima Concepción, near Lompoc, California, is a state historical monument. It was founded in 1787.

Nombre de Díos, in St. Augustine, Florida, is the oldest U.S. mission. Its first Mass was celebrated in 1565.

Nuestra Señora del Carmen, near El Paso, was founded by Franciscans in 1682 as a refuge from the Pueblo Revolt of 1680.

San Antonio de Valero, in San Antonio, is better known as the Alamo. It was the site of a famous battle in 1836, during the Texas Revolution.

Santa Bárbara, in Santa Barbara, California, has been called Queen of the California Missions because of its architectural beauty. Today, it is a Franciscan parish.

San Esteban Rey de Acoma, at Acoma, New Mexico, was constructed during the 1630's. It is one of the few churches that survived the Pueblo Revolt of 1680. It stands atop an isolated *mesa* (tableland) 365 feet (111 meters) high.

San José, in San Antonio, is part of San Antonio Missions National Historical Park. It was founded in 1720 by the Franciscan Antonio Margil de Jesús.

San Juan Capistrano, in San Juan Capistrano, California, was established by the Franciscan Junípero Serra in 1776. An earthquake destroyed most of it in 1812.

San Xavier del Bac, near Tucson, Arizona, still serves local Tohono O'odham (also known as Papago Indians). The Jesuit Eusebio Francisco Kino first visited the site in 1692 and founded a mission there in 1700. John L. Kessell

Missionary is a person sent by a religious group to convert others to his or her faith. Many missionaries also work to provide education, agricultural information, medical care, and other social services to the people they serve.

Religions attract converts in various ways. Buddhist organizations spread the teachings of Buddha throughout the world by sponsoring lectures and meditation sessions. Islamic missionaries conduct worship services and distribute religious literature. Some religions today, including Judaism, have no missionaries because they do not seek converts. Christianity carries on the most extensive missionary activities. This article discusses Christian missionaries.

Men and women may serve as *foreign missionaries* or *home missionaries.* Foreign missionaries leave their own countries and work abroad. Today, the whole world, especially its huge cities, is considered a mission field. Missionaries are sent to other countries from Asia, Africa, and Latin America, as well as from North America and Europe. Home missionaries carry out assignments in their own lands.

There are hundreds of thousands of Christian missionaries. Many missionaries are members of the clergy. Many men and women who are not ordained and do not belong to religious orders serve as *lay missionaries.* There has been a large growth in the number of people serving short terms as missionaries.

Duties. Christian missionaries explain the teachings of their faith and try to inspire devotion to Jesus Christ. They lead worship services, preach sermons, translate the Bible, write religious materials, organize churches, and guide converts in the practice of their faith.

Many missionaries also use their skills to relieve poverty and disease among the people they serve. Others provide relief from such disasters as earthquakes, famines, floods, and storms. Missionaries usually work through national schools and hospitals. But in some remote areas, they still provide the only education and health care available. Missionaries who have technical skills may train people in business methods, construction trades, or improved farming techniques.

Some missionary organizations direct their efforts to special groups. Such organizations as Inter-Varsity Christian Fellowship, Youth for Christ, Campus Crusade

for Christ, and Navigators work with students. Prison Fellowship Ministries works with people in prisons.

Several groups loosely related to Christian denominations place special emphasis on conversion. All Jehovah's Witnesses must work at least 10 hours each month spreading their faith to people on street corners and in private homes. Many Mormons who are young adults or retired people volunteer to spend up to two years as full-time missionaries without pay. Some organizations express their faith chiefly through social work and acts of charity. The Salvation Army is one of the largest such organizations in the world.

Organization. Today, about two-thirds of all Christian missionaries are Roman Catholics, and the rest are Protestants. The fastest-growing groups belong to evangelical Protestant denominations, especially charismatic and Pentecostal churches. More missionaries come from the United States than from any other country.

Several Catholic religious orders devote much of their efforts to missionary activities. These groups include the Catholic Foreign Mission Society of America (Maryknoll) and the Society of Jesus (Jesuits). The Congregation for the Evangelization of Peoples or Propagation of the Faith directs worldwide Catholic mission work. Protestant missionaries are recruited and financed by denominations, church-sponsored organizations, and independent agencies. The Division of World Mission and Evangelism of the World Council of Churches coordinates much Protestant missionary activity. The Evangelical Foreign Missions Association and the Interdenominational Foreign Mission Association perform this service for evangelical Protestants.

History. Christian missionary work began soon after that religion was founded nearly 2,000 years ago. Christianity spread rapidly because of such enthusiastic missionary activity as that of the apostles Peter and Paul. By the 300's, Christianity had spread throughout the Roman Empire, including North Africa. The missionary Saint Patrick brought Christianity to Ireland in the 400's. During the Middle Ages, such Christian missionaries as Saint Boniface converted the people of most European countries. By the 1500's, Roman Catholic missionaries were sailing with European explorers and soldiers to little-known regions of Africa, Asia, and the Americas. During the 1500's and 1600's, Dominicans, Franciscans, and Jesuits and other Catholic orders set up many missions throughout the world.

The Protestant missionary movement began in the 1600's, when Protestant nations of Europe established trading companies and colonies overseas. John Eliot and David Brainerd were famous early missionaries to American Indians. In the 1800's, thousands of missionaries, including William Carey, David Livingstone, and Robert Morrison, worked in the Far East and Africa. The period became known as "the great century" of Protestant missions.

Revivalist preachers, such as Jonathan Edwards and George Whitefield, sought converts among American colonists in the 1700's. Later, revivalists from Baptist, Methodist, and other churches won converts and established congregations on the U.S. frontier. Revivalists of the 1800's and early 1900's gained converts in the growing cities. Now, evangelists such as Billy Graham use large crusades, radio, and television to seek converts.

Many people in mission lands resented foreign missionary activity. This resentment arose partly because missionaries often promoted foreign political and economic interests among the people with whom they worked. Also, missionaries often considered Western ways of life superior to the customs and values of native cultures, which they tried to change. Some missionaries supported governments that ignored the needs of the poor. At the same time, missionaries often won respect for their work in health, education, and other fields.

A strong sense of patriotic unity called *nationalism* swept through many developing countries after World War II ended in 1945. In time, these countries won independence, and the churches there appointed more national leaders to replace the missionaries. Some of the countries opposed missionary activity, seized church-supported schools, and even deported or killed missionaries.

Today, more missionaries than ever before are at work throughout the world. Increasing numbers are being sent by churches in Africa, Asia, Latin America, and many of the Pacific Islands. They use modern methods of communication and scientific studies to help them in their work. They often cooperate with local churches.

Mississauga, *MIHS uh SAW guh* (pop. 612,925), is one of the largest cities in Ontario, Canada. It was created in 1976 by combining several villages and towns west of Toronto. For location, see Ontario (political map).

Mississauga's downtown area is in the center of the city. It includes the Civic Centre, which is the home of the city government; and Square One, a large shopping and office complex. Canada's busiest airport, Lester B. Pearson International Airport, is located on the northeast side of the city. Mississauga's industries include the production of aerospace equipment, electronic products, scientific instruments, and pharmaceuticals.

Mississauga is located on land purchased from the Mississauga Indians in 1805. Several communities sprung up in the area. The town of Mississauga was incorporated in 1968. In 1976, the Ontario government combined the town and about 110 square miles (290 square kilometers) of towns, townships, and villages to form the city of Mississauga. Many of these communities retain their small-town atmosphere. Lou Clancy

Bruce Coleman Inc

Mississippi's stately old homes like Rosalie, *shown here,* a mansion in Natchez, are reminders of life in the Old South. Natchez is the oldest town along the Mississippi River.

Mississippi *The Magnolia State*

Mississippi is a state that is going through a period of great change. Part of the Deep South of the United States, it was once a land of farmers and quiet towns. It is becoming a state of office workers and busy cities. Since the 1930's, the people of Mississippi have worked to build a modern economy based on industry as well as agriculture.

But tradition still plays an important part in Mississippi life. The people of Mississippi have great pride in their state's history. Mississippi retains many reminders of the Old South. Stately *antebellum* (pre-Civil War) mansions bring back memories of Mississippi plantation life before the Civil War, which began in 1861. Monuments throughout Mississippi recall the heroism of the Confederate soldiers who fought on the state's battlefields.

Today, most of Mississippi's workers are employed in the service industies, which include retail trade, government, and the growing casino gaming and telecommunications industries. Factories also employ many people. Goods manufactured in the state include appliances, chemicals, furniture, meat products, and ships.

Farmland and forest-covered hills spread over most of the state. Many Mississippi farmlands are used to raise cattle or chickens. Others are used to grow crops. Mississippi ranks among the leading producers of chickens and cotton. The state also has significant deposits of petroleum and natural gas.

Despite the growth in the state's economic base, many of the jobs in Mississippi pay low wages. As a result, the average income in Mississippi is lower than in any other state.

Mississippi takes its name from the mighty river that forms most of its western border. *Mississippi* means the *Big River,* the *Great Water,* or the *Father of Waters,* in the language of the Indians who lived in the region in early times. Mississippi's nickname, the *Magnolia State,* comes from the magnolia trees that grow in most parts of the state. Mississippi's climate, which is generally warm and moist, allows garden flowers such as azaleas and camelias to bloom for months each year.

The mild climate attracts many tourists to Mississippi. The Mississippi Gulf Coast is a popular vacationland. It has large, sunny beaches that are lined with many fine hotels. Jackson is the capital of Mississippi and the state's largest city.

The contributors of this article are John Ray Skates, Jr., Professor of History, and Robert W. Wales, Professor of Geography, both at the University of Southern Mississippi.

Interesting facts about Mississippi

The world's first heart transplant into a human being was performed by Dr. James D. Hardy at the University of Mississippi Medical Center in Jackson in 1964. Hardy replaced a human heart with the heart of a chimpanzee. The operation introduced important techniques used in later successful human-to-human heart transplants.

First heart transplant

The Pascagoula River is known as the *Singing River.* The sound it makes, best heard in warm months toward evening, resembles the sound of a swarm of bees in flight. According to an Indian legend, a young chieftain of the Pascagoula tribe wooed and won a princess of the rival Biloxi tribe who was already engaged. The furious Biloxi attacked the Pascagoula, demanding the surrender of the offending chieftain. The Pascagoula refused. Realizing they could not escape, they joined hands with the ill-fated couple and walked, singing, into the river.

Coca-Cola was first bottled in 1894 by Joseph A. Biedenharn, a candy store owner in Vicksburg.

Grenada was formed in 1836 by the union of two rival towns, Pittsburg and Tullahoma. The union was symbolized by an actual wedding ceremony in which the groom came from Pittsburg and the bride from Tullahoma.

The last world heavyweight bare-knuckle boxing championship was fought in Richburg, near Hattiesburg, in 1889. John L. Sullivan defeated Jake Kilrain in 75 rounds.

Jackson is Mississippi's capital and largest city. Known as the *Crossroads of the South,* it serves as a center of commerce, industry, and transportation.

Mississippi in brief

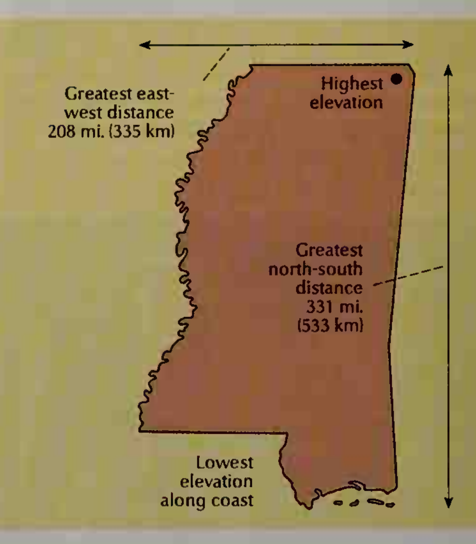
Symbols of Mississippi

The state flag was adopted in 1894. The bars of red, white, and blue are the national colors. A replica of the Confederate battle flag occupies the upper left portion. The state seal, adopted in 1817, bears a modified version of the arms of the United States. The eagle holds an olive branch and arrows, symbolizing the desire for peace but the ability to wage war.

State flag

State seal

Mississippi (brown) ranks 32nd in size among all the states and 7th in size among the Southern States (yellow).



The State Capitol is in Jackson, Mississippi's capital since 1822. Other capitals were Natchez (1798-1802, 1817-1821), Washington (1802-1817), and Columbia (1821-1822).

General information

Statehood: Dec. 10, 1817, the 20th state.
State abbreviations: Miss. (traditional); MS (postal).
State motto: *Virtute et Armis* (By Valor and Arms).
State song: "Go Mis-sis-sip-pi" by Houston Davis.

Land and climate

Area: 47,695 sq. mi. (123,530 km²), including 781 sq. mi. (2,024 km²) of inland water but excluding 591 sq. mi. (1,530 km²) of coastal water.
Elevation: *Highest*—Woodall Mountain, 806 ft. (246 m) above sea level. *Lowest*—sea level along the coast.
Coastline: 44 mi. (71 km).
Record high temperature: 115 °F (46 °C) at Holly Springs on July 29, 1930.
Record low temperature: −19 °F (−28 °C) at Corinth on Jan. 30, 1966.
Average July temperature: 81 °F (27 °C).
Average January temperature: 46 °F (8 °C).
Average yearly precipitation: 56 in. (142 cm).

Important dates

1540 Hernando de Soto of Spain entered the Mississippi region.

1699 Pierre Le Moyne, Sieur d'Iberville, established the first European settlement in Mississippi at Old Biloxi.

1763 Mississippi became English territory after the French and Indian War.

1798 Congress organized the Mississippi Territory.
1817 Mississippi became the 20th state on December 10.
1939 Petroleum was discovered at Tinsley.
1969 A federal court ordered the desegregation of Mississippi schools.
1985 Completion of the Tennessee-Tombigbee Waterway gave Mississippi a new shipping route to the Gulf of Mexico.

People

Population. The 2000 United States census reported that Mississippi had 2,844,658 people. The population had increased 10 $\frac{1}{2}$ percent over the 1990 figure, 2,573,216. According to the 2000 census, Mississippi ranks 31st in population among the 50 states.

About 36 percent of Mississippi's people live in metropolitan areas (see **Metropolitan area**). These areas are Biloxi-Gulfport-Pascagoula, Hattiesburg, and Jackson. The Memphis (Tennessee) metropolitan area extends into DeSoto County in Mississippi. The largest city is Jackson, the state capital and center of Mississippi's business and financial activities. Jackson is also Mississippi's largest metropolitan area. The metropolitan area of Biloxi-Gulfport-Pascagoula ranks second in population. For the populations of these areas, see the *Index* to the Mississippi political map.

Mississippi's six largest cities, in order of size, are Jackson, Gulfport, Biloxi, Hattiesburg, Greenville, and Meridian. Of these cities, Gulfport grew the fastest during the 1990's. From 1990 to 2000, its population increased by nearly 75 percent. Several of the state's large cities lie on the Mississippi River. These cities include Greenville, Natchez, and Vicksburg.

The 2000 census showed that 36 percent of the people in Mississippi are African Americans. This is a larger proportion of African Americans than in any other state. Hispanic Americans, the state's next largest minority group, account for just over 1 percent of the population. Mississippi's other large population groups include people of Irish, English, German, and American Indian descent.

Schools. Mississippi's first permanent schools were established in the early 1800's. The Mississippi public school system was established by the Constitution of

St. Paul's Seafood Festival is held each July in Pass Christian. The festival features arts, crafts, and seafood dinners.

1869. The state set up a board of education and provided that every child should receive free schooling for four months each year. At first, most Mississippians opposed public schools. The Civil War had caused hard times, and the people had little money for school taxes. But by the end of the 1890's, conditions had improved and the Mississippi public school system had won general approval.

In the early 1900's, a large majority of Mississippi's school-age children lived in rural areas. Many rural schools were very small and had limited resources. The state government tried to improve schools by consolidating small districts (see **Consolidated school**). The state also established agricultural high schools, which offered instruction in agricultural methods and home economics in addition to other high school subjects. During the 1920's, Mississippi's first junior colleges grew out of some of the agricultural high schools.

Like other Southern states, Mississippi had separate schools for blacks and whites for many years. In 1954, the Supreme Court of the United States ruled that public school segregation on the basis of race is unconstitutional. The first racial integration in Mississippi public schools took place in 1964. Today, all the state's public school districts are integrated. Children from 6 through 16 years of age must attend school.

The state superintendent of public education directs Mississippi's elementary and secondary schools. A nine-member State Board of Education selects the superintendent. The governor appoints five of the Board of Education members. The lieutenant governor and the speaker of the state House of Representatives each appoint two members of the board. All board members serve nine-year terms. For the number of students and teachers in Mississippi, see **Education** (table).

Libraries. The first public library in Mississippi was established in Port Gibson in 1818. Today, there are about 250 public libraries in the state.

Several college and university libraries in Mississippi have outstanding collections. These collections include the William Faulkner collection at the University of Mississippi, the John C. Stennis collection at Mississippi State University, and the Lena Y. de Grummond and Cleanth Brooks literature collections at the University of Southern Mississippi. The Mississippi Department of Archives library has the most complete collection of historical information on Mississippi.

Museums. Mississippi has one of the nation's finest historical museums. It is housed in the restored Old Capitol in Jackson. Other historical museums include the Old Courthouse Museum in Vicksburg and the Jefferson Davis Museum at Beauvoir House near Biloxi.

Art museums in Mississippi include the Mississippi Museum of Art in Jackson, the Mary Buie Museum in Oxford, and the Lauren Rogers Museum of Art in Laurel. The Mississippi Museum of Natural Science, located in Jackson, features many exhibits relating to natural history.

The Gulf Coast of Mississippi is one of the nation's most popular resort regions. This vacationland has won fame for its large, sunny beaches and fine hotels. In other parts of the state, historic monuments and pleasant wooded areas are the chief attractions.

Thousands of visitors also take tours of Mississippi's many old mansions and plantations where hostesses dressed in billowing hoop skirts serve as guides during spring and fall "pilgrimages." There, visitors can get some idea of what life was like in Mississippi before the Civil War.

Excellent hunting and fishing in about 30 Wildlife Management areas attract many people to Mississippi. Hunters may shoot such animals as wild doves, ducks, geese, quail, turkeys, deer, rabbits, raccoons, and squirrels. Thousands of Mississippi ponds and lakes have been stocked with fish. People can cast in fresh water for bass, bream, crappies, and other fishes. Or they may sit lazily on the banks of a Mississippi river or pond and wait for catfish to take their bait. Saltwater fishing enthusiasts fight big game fish in the waters off the Gulf Coast of Mississippi.

One of the highlights of Mississippi's many annual events is the Shrimp Festival in Biloxi. This event takes place during the first week of May. The Shrimp Festival marks the opening of the shrimp-fishing season in Mississippi. Highlights of the celebration include the blessing of the shrimp fleet.

Places to visit

Following are brief descriptions of some of Mississippi's most interesting places to visit:

Capitols, in Jackson, offer many reminders of the state's rich history. The Old Capitol, now the State Historical Museum, was built chiefly by slave labor between 1833 and 1842. Here, Mississippi voted in January 1861 to secede from the Union. The New Capitol, which was built in 1903, houses the state Legislature and the governor's offices.

Churches. The Church of the Holy Trinity in Vicksburg, completed in 1880, has a memorial honoring the Union and Confederate soldiers who fought in the siege of Vicksburg. St. Paul's Episcopal Church in Woodville dates from 1824, and the First Presbyterian Church in Port Gibson from 1829.

Delta Blues Museum, in Clarksdale, includes videotaped presentations, photographs, sound-and-slide shows, and memorabilia of the blues artists and their music.

Elvis Presley's birthplace, at Tupelo in northeastern Mississippi, marks the site where the famous singer was born. The tiny house where Presley spent his early years is now part of Elvis Presley Park.

Florewood River Plantation, in the Delta near Greenwood, is a state park and museum. It has 22 buildings that show what life was like on a cotton plantation before the Civil War.

Fort Massachusetts, on Ship Island, was a Union stronghold during the Civil War. Union forces captured the fort from the Confederates in 1861. Another interesting historic site is the Old Spanish Fort in Pascagoula, one of the oldest buildings on the Gulf Coast. It was part of a settlement and fort built in 1718.

Mount Locust is a restored inn along the Natchez Trace Parkway near Fayette. It was built in 1777 as a stopping place for travelers on the Natchez Trace, an important pioneer route between Natchez and Nashville, Tennessee.

Petrified Forest, near Flora, contains giant stone trees dating back 30 million years. Facilities there include a nature trail, a geological museum, a rock and gem shop, and picnic areas.

Smith Robertson Museum and Cultural Center, in Jackson, has exhibits that depict the experience and heritage of black Mississippians from their African roots to the present. The museum is housed in the former Smith Robertson School, the first public school for blacks in Jackson.

Stately old homes in or near Natchez are reminders of the way of life of wealthy Mississippians before the Civil War. These mansions include Auburn (built in 1812), D'Evereux (1840), Dunleith (1856), Edgewood (1860), Gloucester (1803), Linden (1800), Melrose (1845), Monteigne (1855), Longwood (1860), Rosalie (1820), and Stanton Hall (1857). Cedar Grove (1842) and Duff Green (1856) are in Vicksburg. Other homes include Temple Heights (1837) in Columbus, Waverley (1852) near Columbus, and Grey Gables (1830) in Holly Springs.

Jefferson Davis spent his boyhood at Rosemont, near Woodville. At Biloxi stands Beauvoir, Davis' last home. Beauvoir is now a shrine and a museum.

Vicksburg National Military Park honors the siege of Vicksburg, which lasted from May 19 to July 4, 1863. The siege, which ended in a Union victory, was a major turning point of the Civil War. Monuments in the park honor the states represented in the battle. Each state's monument is located at the site where that state's troops drew their battle lines.

National forests. Mississippi has six national forests. The largest of these is De Soto in southeastern Mississippi. The state's other five national forests are Homochitto in the southwest; Bienville, Delta, and Tombigbee in central Mississippi; and Holly Springs in the northern part of the state.

State parks. Mississippi has 27 state parks. For information on these state parks, write to Department of Wildlife, Fisheries and Parks, P.O. Box 23093, Jackson, MS 39225.

Annual events

January-February

Dixie National Livestock Show and Rodeo in Jackson (February); Mardi Gras festivities in various cities on the Mississippi Gulf Coast and in Natchez (February).

March-June

Garden Club Pilgrimages of Antebellum Homes in Aberdeen, Columbus, Holly Springs, Natchez, Port Gibson, Vicksburg, and other communities (March-April); D'Iberville Landing and Historical Ball in Ocean Springs (April); Natchez Trace Festival in Kosciusko (April); Railroad Festival in Amory (April); World Catfish Festival in Belzoni (April); Atwood Bluegrass Festival in Monticello (May); Jubilee Jam Art and Music Festival in Jackson (May); Flea Market in Canton (May); Jimmie Rodgers Memorial Festival in Meridian (May); Civil War Re-enactment in Vicksburg (May); Blessing of the Fleet and Shrimp Festival in Biloxi (May); Mississippi International Balloon Classic in Greenwood (June).

July-September

Choctaw Indian Fair in Philadelphia (July); Mississippi Deep Sea Fishing Rodeo in Gulfport (July); Watermelon Festival in Mize (July); Crop Day in Greenwood (August); Neshoba County Fair in Philadelphia (August); Delta Blues Festival in Greenville (September); Seafood Festival in Biloxi (September).

October-December

Mississippi State Fair in Jackson (second week of October); Natchez Fall Pilgrimage in Natchez (October); Scottish Highland Games in Biloxi (November); Christmas in Natchez (December); Trees of Christmas Festival in Meridian (December).

Blessing of the fleet at the Biloxi Shrimp Festival

Land and climate

Land regions. Mississippi has two main land regions: (1) the Mississippi Alluvial Plain, and (2) the East Gulf Coastal Plain.

The Mississippi Alluvial Plain covers the entire western edge of the state. It consists of fertile lowlands and forms part of the 35,000-square-mile (90,600-square-kilometer) Alluvial Plain of the Mississippi River. The region is quite narrow south of Vicksburg. North of the city, the plain spreads out and covers the area between the Mississippi River and the Yazoo, Tallahatchie, and Coldwater rivers. Floodwaters of the rivers have enriched the soil of the region with deposits of silt. The fertile soil of the Mississippi Alluvial Plain is famous for its large cotton and soybean crops. Most Mississippians call this region the *Delta.*

The East Gulf Coastal Plain extends over all the state east of the Alluvial Plain. Most of the region is made up of low, rolling, forested hills. The coastal plain also has prairies and lowlands. Yellowish-brown *loess* (soil blown by winds) covers the region in the west. Most Mississippians call these deposits the Cane, Bluff, or Loess Hills. The Tennessee River Hills rise in northeastern Mississippi. They include the highest point in the state, 806-foot (246-meter) Woodall Mountain. The Pine Hills, often called the Piney Woods, rise in the southeastern part of the region. They are covered largely with longleaf and slash-pine forests.

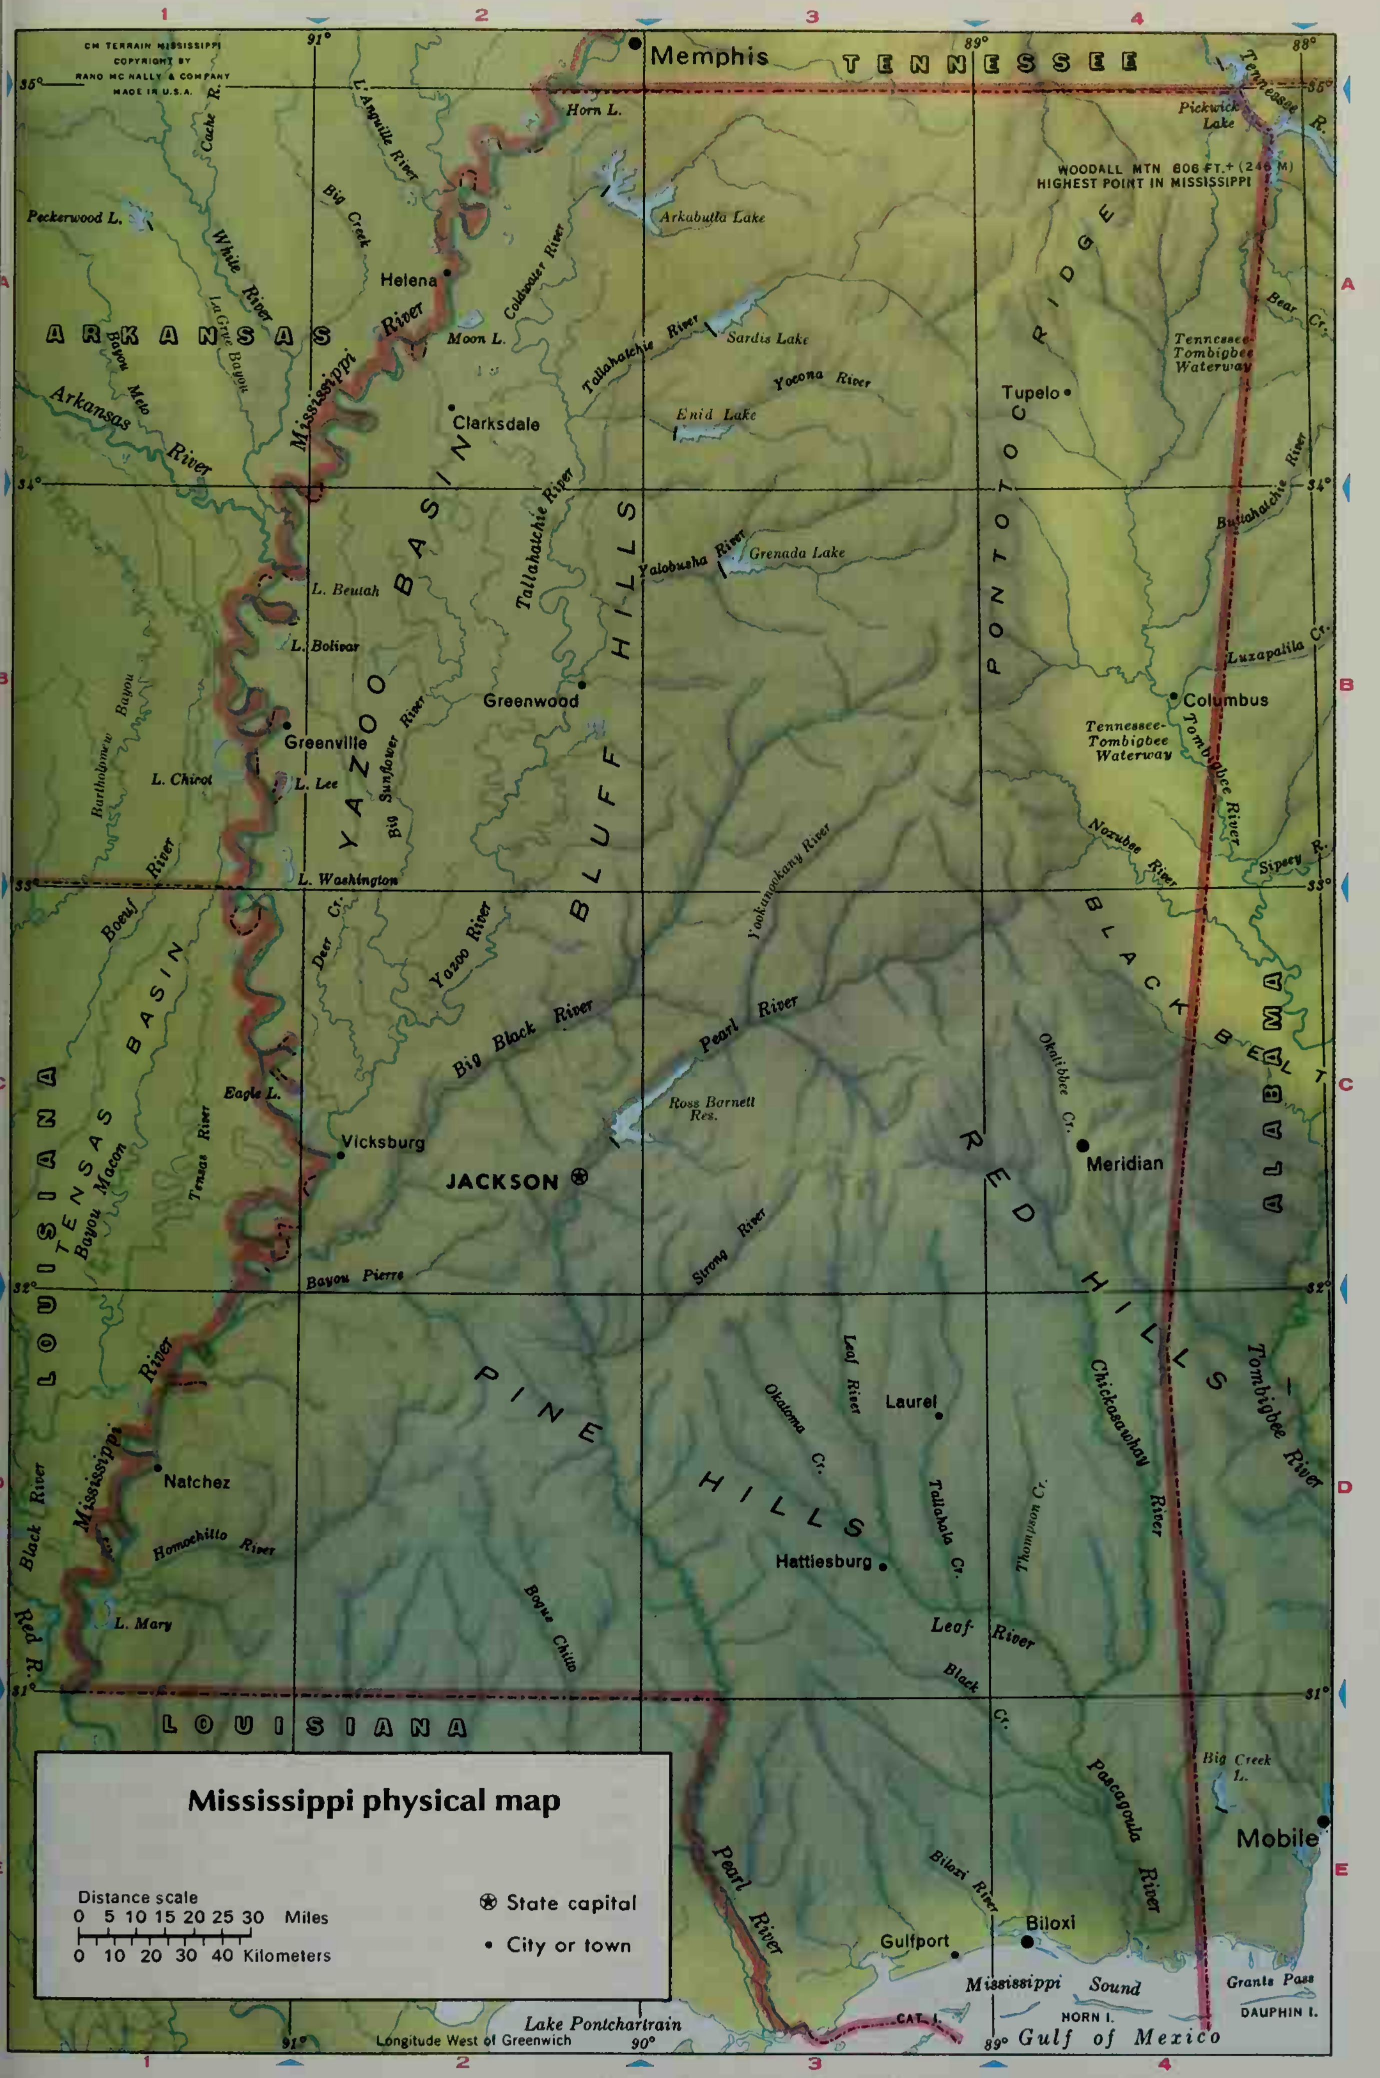
The main prairie is called the *Black Belt* or *Black Prairie* because its soil is largely black in color. This long, narrow prairie lies in the northeast section of the state. The Black Belt stretches through 10 counties. Livestock graze there, and corn and hay grow well on the farmlands of the Black Belt. Small prairies also lie in central Mississippi, east of Jackson. Along the Mississippi Sound, lowlands stretch inland over the southern portion of the region.

Coastline. Mississippi has a coastline of 44 miles (71 kilometers) along the Gulf of Mexico. With bays and coves, it has a total shoreline of 359 miles (578 kilometers). The largest bays include Biloxi, St. Louis, and Pascagoula. The nation's longest sea wall protects about 25 miles (40 kilometers) of coastline between Biloxi and Point Henderson at Pass Christian. Other coastal towns include Bay St. Louis, Gulfport, and Ocean Springs. Deer Island is near the mouth of Biloxi Bay, and a chain of small islands lies off the coast. They include Cat, Horn, Ship, and Petit Bois islands. Mississippi Sound separates them from the mainland.

Rivers and lakes. Mississippi has many rivers and lakes. The nation's most important river, the Mississippi, forms most of the state's western border. Its floodwaters, in earlier times, often deposited silt on the land, and helped make the land fertile. In some years, heavy floods damaged crops and homes. Today, wide *levees* (dikes) help protect many areas against damaging floods (see **Levee; Mississippi River**).

The state has several main river basins. The rivers of the western and north-central basin drain into the Mississippi River. These rivers include the Big Black River and the Yazoo River with its tributaries, the Coldwater,

© Dan Guravich



The Yazoo River flows through the Mississippi Alluvial Plain, a region known to most Mississippians as the *Delta.* The region's fertile soil produces large cotton and soybean crops.

Specially created for *The World Book Encyclopedia* by Rand McNally and World Book editors

© Dan Guravich

The Piney Woods cover most of southeastern Mississippi in the state's East Gulf Coastal Plain region. These abundant pine forests provide pine oil, rosin, and turpentine, as well as lumber.

Big Sunflower, and Tallahatchie rivers. Rivers of the eastern basin drain into the Gulf of Mexico. They include the Pearl, Pascagoula, and Tombigbee. Many of Mississippi's lakes are artificially created reservoirs, such as Pickwick Lake in the northeastern corner of the state. Other artificially created lakes include Arkabutla, Enid, Grenada, and Sardis, all in north-central Mississippi. These lakes lie behind flood-control dams. In the early 1960's, the large Ross Barnett Reservoir was built on the Pearl River near Jackson.

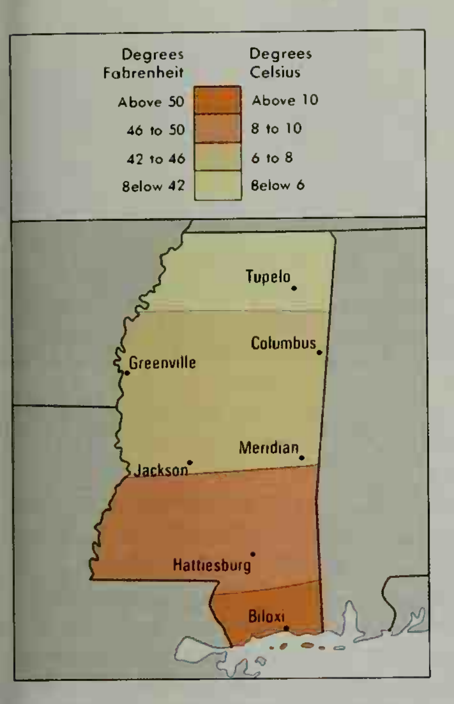
The Mississippi River has formed many *oxbow lakes,* mostly north of Vicksburg. These lakes are crescent-shaped bodies of water that used to be curves of rivers before they became cut off from the main streams. Oxbow lakes found in Mississippi include Beulah, Lee, Moon, and Washington. Mississippi also has many slow-moving streams called *bayous.* Some of the bayous connect the lakes with the rivers in the Delta. Others link the inland waterways with the Gulf of Mexico.

Plant and animal life. Forests cover more than half of Mississippi. Pine trees are important as a source of lumber. Loblolly, longleaf, and slash pines grow in the Piney Woods area. The shortleaf pine grows in the northern and central sections of the state. Other trees that grow in Mississippi include the ash, baldcypress, cottonwood, elm, hickory, oak, pecan, sweet gum, and tupelo.

The magnolia, an evergreen tree with fragrant white flowers, grows throughout the state. The magnolia is Mississippi's state flower. Many parts of the state also have azaleas, black-eyed Susans, camellias, crepe myrtle, dogwood, redbud, violets, Virginia creepers, and pink and white Cherokee roses.

Animal life in Mississippi includes beavers, deer, foxes, opossums, rabbits, and squirrels. Among the state's game birds are wild doves, ducks, quails, and turkeys. The mockingbird is Mississippi's state bird. Freshwater fish found in the state's waters include bass, bream, catfish, and crappies. In the Gulf waters are crabs, oysters, shrimp, menhaden, mackerel, and speckled trout.

Climate. Mississippi has a warm, moist climate with long summers and short winters. In July, Mississippi temperatures average about 81 °F (27 °C). Winds from the Gulf of Mexico and frequent thundershowers cool much of the state during the summers. Even in the interior of the state, the temperature seldom rises above 100 °F (38 °C). However, temperatures of 90 °F (32 °C) or higher occur about 55 days a year on the Gulf Coast and more often in the interior. The highest temperature recorded in Mississippi was 115 °F (46 °C) at Holly Springs on July 29, 1930.



January temperatures average 46 °F (8 °C) in Mississippi. The lowest temperature was −19 °F (−28 °C), recorded at Corinth on Jan. 30, 1966. Northern and central Mississippi occasionally have ice and snow. The Gulf Coast ordinarily has a frost-free season of 250 to 300 days.

Mississippi's *precipitation* (rain, melted snow, and other forms of moisture) ranges from about 50 inches (130 centimeters) a year in the northwestern part of the state to about 65 inches (165 centimeters) in the southeastern part. Hurricanes sometimes sweep northward from the Gulf in late summer and fall.

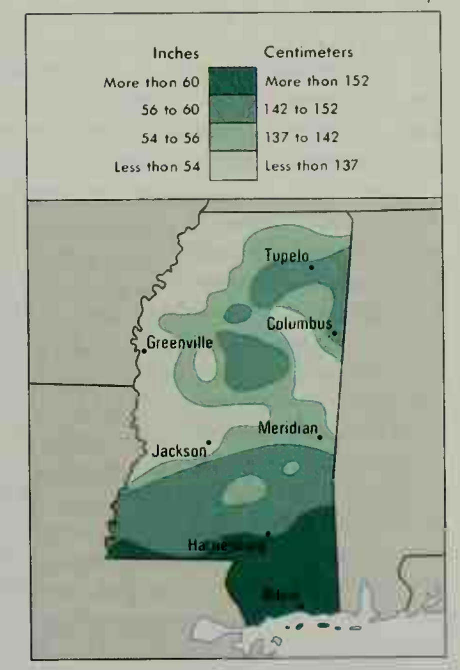
Average January temperatures
Mississippi has mild winters. The mildest weather occurs in the far south. Temperatures decrease to the north.



Average July temperatures
Mississippi has hot summers with little temperature variation. The west and south are slightly warmer.

Average yearly precipitation
Mississippi has a rainy climate. The heaviest rains fall in the far south, brought by winds from the Gulf of Mexico.

WORLD BOOK maps

Economy

Mississippi's economy has long relied on traditional industries, such as manufacturing and agriculture. Manufacturing remains a leading economic activity in the state. But service industries, which include such fields as casino gaming and telecommunications, are of growing importance to the state.

Natural resources of Mississippi include rich soils, abundant water supplies, valuable mineral deposits, and large forests.

Soil and water are the state's most important natural resources. The Mississippi Alluvial Plain has some of the richest soil in the United States. Much of this fertile earth is silt deposited by floodwaters of the Mississippi River. Another fertile area of clay loam soils is in the Black Belt. These soils are gray or black in color. Sandy loam soil covers most of the East Gulf Coastal Plain. Mississippi has great supplies of surface water, and also many wells. Together, they furnish abundant fresh water for home and industrial use.

Minerals. Petroleum is the most valuable mined resource of Mississippi. The chief oil deposits are in southern Mississippi. The state also has valuable deposits of natural gas. The largest deposits are located in the south-central and southwestern counties.

Mississippi has many kinds of clays that are used by industry. They include bentonite, used to lubricate oil well drills, and fuller's earth, used in refining fats and oils. Other clays are ball clays and certain clays suitable for making brick and tile.

Large deposits of sand and gravel are found in the state. Tishomingo County has large deposits of sandstone. Other mined resources include limestone and *lignite,* a kind of coal.

Forests cover more than half of Mississippi. They provide the raw materials for a huge output of products that make Mississippi a leading forest industry state. About 120 kinds of trees grow in Mississippi. The most important are the loblolly, longleaf, and slash pines of the Piney Woods area, and the shortleaf pine of northern and central Mississippi. Other trees include the ash, baldcypress, cottonwood, elm, hickory, oak, pecan, sweet gum, and tupelo. Mississippi conducts a wide-

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total

Community, business, & personal services	17	361,200	24
Wholesale & retail trade	17	288,800	20
Government	15	259,400	18
Finance, insurance, & real estate	11	70,700	5
Transportation, communication, & utilities	10	64,300	4
Construction	4	83,800	6
Agriculture	3	71,900	5
Mining	1	9,500	1
Total	100	1,462,800	100

*GSP = gross state product, the total value of goods and services produced in a year.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

spread program of planting young trees to replace those that are cut down. Mississippi has about 5,700 tree farms—more than any other state.

Service industries provide the largest part of Mississippi's *gross state product*—the total value of all goods and services produced in a state in a year. The two leading service industries are (1) community, business, and personal services and (2) wholesale and retail trade. Each of these two industries contributes an equal portion of the gross state product.

Community, business, and personal services employ more people than any other industry group in Mississippi. Such services include private health care, hotels and casinos, law firms, and repair shops. More than half of the hotel revenue comes from the Biloxi and Jackson areas. Casino gaming has become a huge industry in the state, which trails only Nevada and New Jersey in casino income. The state's roughly 30 casinos employ about 40,000 people. Many casinos are based in Tunica County, just south of Memphis, Tennessee.

Wholesale and retail trade is also a leading employer in Mississippi. The wholesale trade of automobiles, farm and forest products, and petroleum is especially important in the state. Retail trade is a leading employer. Major retailers include automobile dealerships, grocery stores, and restaurants. Jackson is the state's leading center of trade.

Government services rank third among the service industries in Mississippi. These services include the operation of public schools and hospitals, and military establishments. State and local education systems are the leading government employers. Major military establishments in the state include Keesler Air Force Base in Biloxi and the John C. Stennis Space Center in Hancock County. The Stennis Space Center is the primary rocket test site of the National Aeronautics and Space Administration (NASA).

Finance, insurance, and real estate ranks next. Jackson is Mississippi's leading financial center. Most of the state's major insurance and real estate firms are based in the Jackson area, as are the largest banks. Large banks are also located in Gulfport, Hattiesburg, and Tupelo.

Transportation, communication, and utilities are the state's fifth-ranking service industry. Mississippi's location in the heart of the Southeast and along the Mississippi River makes it an important transportation state. Also, telecommunications has become a major industry in the state. WorldCom, Inc., one of the nation's largest such companies, is headquartered in Clinton. More information about transportation and communication appears later in this section.

Manufacturing. Goods manufactured in Mississippi have an annual *value added by manufacture* of about $17 billion. This figure represents the increase in value of raw materials after they become finished products. Mississippi has one of the most diverse manufacturing sectors of any state. The five leading manufactured products generate nearly equal amounts of income.

Processed foods are Mississippi's leading type of manufactured product. Meat packing is especially important in the state. Forest, Laurel, and Morton have large poultry processing plants. Other important food products include beverages, dairy products, grain products, and seasonings.

Transportation equipment is Mississippi's second most important manufactured product in terms of value added by manufacture. Motor vehicle parts and ships are this industry's leading products. Factories near Jackson produce electrical parts for motor vehicles. Shipyards in Pascagoula build freighters and tankers.

Chemicals rank third among Mississippi's manufactured products. Leading types of chemical products include industrial chemicals and pharmaceuticals.

Ranking fourth among the state's manufactures are electrical products. Important types of electrical equipment include appliances, generators, lighting and wiring equipment, motors, and stereo systems.

Furniture is the state's fifth-ranking manufactured product. Mississippi ranks among the leading states in upholstered furniture production. Factories that produce furniture are located primarily in northeastern Mississippi, near Tupelo.

Other products manufactured in Mississippi include machinery, paper products, rubber and plastic products, and wood products. Engines and turbines, and farm, construction, and refrigeration equipment are the state's leading types of machinery. Large paper mills operate at Grenada, Laurel, Monticello, Moss Point, New Augusta, and Vicksburg. Leading rubber and plastic

Economy of Mississippi

This map shows the economic uses of land in Mississippi and where the state's leading farm, mineral, and forest products are produced. The major manufacturing centers are shown in red.

WORLD BOOK map

Harris Barnes, Jr.

Cotton is one of Mississippi's most valuable farm products. These mechanical pickers are harvesting cotton in the Delta.

products include tires, plastic bottles, and plastic plumbing fixtures. Large wood-processing plants operate in Columbus, Laurel, Louisville, and Vicksburg.

Agriculture. Mississippi has about 42,000 farms. Farmland covers about 40 percent of the state.

Broilers (chickens from 5 to 12 weeks old) are the leading livestock product in Mississippi. The largest concentration of poultry farms lies within a triangular region formed by Hattiesburg, Jackson, and Meridian. Some farmers raise hens to produce eggs.

Beef and dairy cattle are also major sources of farm income in Mississippi. The state's cattle farmers benefit from the mild climate, which allows for long growing seasons for feed crops. Cattle farms are common in all regions except the Mississippi Delta. Some farmers raise hogs or sheep.

Cotton and soybeans are the state's most valuable crops. Mississippi ranks among the leading producers of cotton. The northwestern part of the state is the major cotton-growing area, and the northeastern part of the state is the major soybean-growing area. Mississippi farmers grow large amounts of corn, grain sorghum, and hay for livestock feed. Other crops include peanuts, rice, and wheat.

Mississippi also produces valuable amounts of cottonseed, greenhouse and nursery products, and pecans. The state's leading vegetables are sweet potatoes, cucumbers, and cowpeas. Important fruits are peaches, watermelons, and muscadine grapes.

Mining. Petroleum and natural gas account for about 90 percent of the value of the state's mined products. Petroleum production is heaviest in the region surrounding Laurel in the southeast part of the state. Major production also occurs in the southwest corner of Mississippi. South-central Mississippi has many natural gas wells. Rankin County accounts for a fifth of the state's natural gas production.

Mississippi's other mined products include clays, crushed stone, and sand and gravel. Clays mined in the state are ball clay, bentonite, common clay, and fuller's earth. Limestone quarries along the state's eastern border are the main source of crushed stone.

Fishing industry. Mississippi is a leading shrimp-fishing state. Biloxi is Mississippi's chief shrimp-packing port. Pascagoula ranks as another center of the state's fishing industry. The saltwater catch includes menhaden, oysters, and red snapper. The freshwater catch in Mississippi includes buffalo fish, carp, and catfish. Mississippi is the leading producer of farm-raised catfish.

Electric power. Coal-burning plants generate about 35 percent of the electric power produced in Mississippi. Nuclear plants supply about 30 percent. Plants that burn petroleum and natural gas each provide an equal share of the rest. Mississippi buys some of its electric power from the Tennessee Valley Authority.

Transportation. Mississippi has one of the finest highway systems in the South. The state has about 73,000 miles (117,000 kilometers) of highways. Jackson has the state's only major commercial airport. About 20 railroads provide freight service, and passenger trains serve about 15 cities in the state.

Mississippi has two major deepwater seaports, Gulfport and Pascagoula. The Mississippi River connects Mississippi with many inland states. The state's leading river ports are Greenville, Natchez, Rosedale, and Vicksburg. The Tennessee-Tombigbee Waterway, which connects the Tennessee and Tombigbee rivers, provides cities in northeastern Mississippi with more direct access to ports on the Gulf of Mexico.

Communication. About 115 newspapers are published in Mississippi, including about 20 dailies. About 35 periodicals also are published in Mississippi. The state has about 150 radio stations and 20 television stations. Cable TV systems and Internet providers serve several communities.

Mississippi's first newspaper, the *Mississippi Gazette,* was established in Natchez in 1799. The oldest newspaper still published in Mississippi, the *Woodville Republican,* was founded in 1823. Dailies with the largest circulations include *The Sun Herald* of Biloxi and Gulfport, *The Clarion-Ledger* of Jackson, and the *Northeast Mississippi Daily Journal* of Tupelo.

Government

Constitution. Mississippi adopted its present Constitution in 1890. The state had three earlier constitutions, adopted in 1817, 1832, and 1869. The Constitution of 1869 was written so that Mississippi could qualify to reenter the Union after the American Civil War. An *amendment* (change) to the Constitution must be approved by two-thirds of the members of each house of the state Legislature. Then the amendment must be approved by a majority of the people voting on the amendment in a general election. The Constitution may also be amended by a constitutional convention that is called by a majority of each house.

Executive. The governor and lieutenant governor of Mississippi are both elected to four-year terms. They may serve any number of terms, but not more than two in a row. Other state executive officers elected to four-year terms in Mississippi include the secretary of state, treasurer, auditor, attorney general, commissioner

of agriculture and commerce, public service and transportation commissioners, and commissioner of insurance. They are elected to four-year terms and may serve any number of terms.

Legislature of Mississippi consists of a Senate of 52 members and a House of Representatives of 122 members. State legislators are elected to four-year terms. Regular legislative sessions begin on the Tuesday after the first Monday in January each year. Most of the sessions last 90 days. The Legislature may extend the sessions. In the first year after a gubernatorial election, the regular session lasts 125 days. The governor may call special sessions.

Courts in Mississippi are headed by the Supreme Court. The people elect the nine Supreme Court justices to eight-year terms. Three are elected from each of three districts that were set up for electing Supreme Court justices. The justice who has served the longest acts as chief justice.

An intermediate Court of Appeals has 10 justices, 2 from each of the state's congressional districts. These justices are also elected to eight-year terms. All other judges are elected to four-year terms. The chief trial courts are chancery courts, whose judges handle civil and equity cases, and circuit courts, whose judges handle civil and criminal cases. Other courts include county, justice, and juvenile courts.

Local government. The county is the chief unit of local government in Mississippi. The state has 82 counties, each with five districts. Voters in each district elect one of the five members of a county board of supervisors, which administers the county. Most cities in Mississippi have a mayor-council form of government. The state Legislature controls the county and city governments.

Revenue. Taxes provide about half of the state government's *general revenue* (income). Most of the state's remaining revenue comes from grants received from the federal government and from other U.S. government programs. Mississippi receives about half of its tax revenue from a general sales tax. Other large sources of tax revenue in the state include taxes on individual income, corporate income, motor fuels, insurance, and motor vehicle licenses. Additional state revenues come from fees paid for services operated by the state government.

Politics. The Democratic Party has controlled Mississippi politics throughout most of the state's history. Since 1876, almost all Mississippi governors and most state and local officials have been Democrats. Before the 1963 election, Republicans rarely nominated candidates for many state and local offices. As a result, nomination by the Democratic Party in primary elections almost always meant election to office. During the 1980's, however, Republican candidates won several United States congressional elections. In 1991, Kirk Fordice became the first Republican to be elected governor of Mississippi since 1874. He held office until 2000.

In every presidential election from 1876 through 1944, Mississippi cast its electoral votes for the Democratic candidate. Since 1948, however, the state has voted mostly for non-Democratic presidential candidates. For Mississippi's electoral votes and voting record in presidential elections, see **Electoral College** (table).

The governors of Mississippi

	Party	Term		Party	Term
David Holmes	* Dem.-Rep.	1817-1820	**Robert Lowry**	Democratic	1882-1890

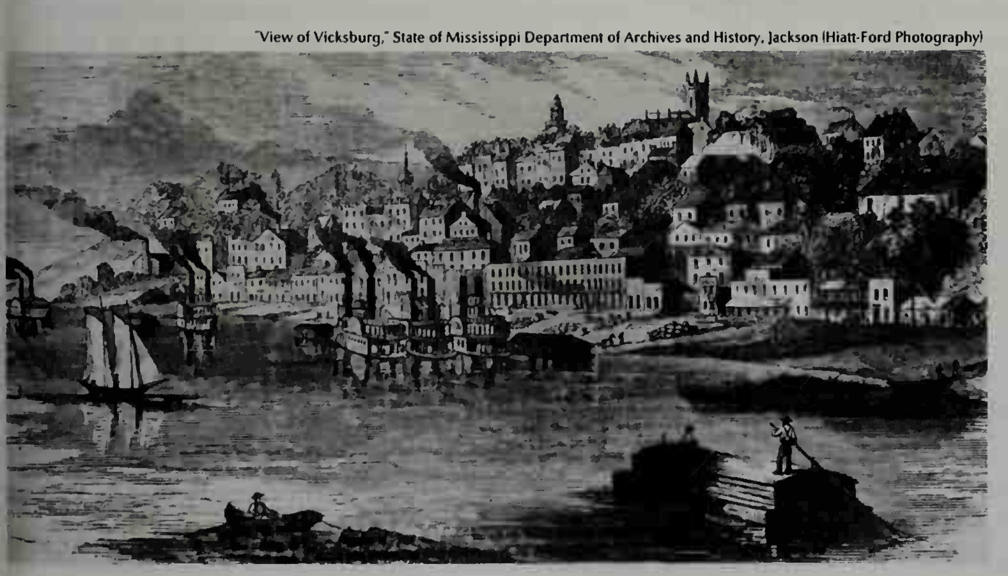
*Democratic-Republican. †Union Democratic. **Whig-Democratic. ‡United States Military Governor.

Indian days. Three powerful Indian tribes once ruled the Mississippi region. The Chickasaw lived in the north and east, the Choctaw in the central area, and the Natchez in the southwest. These tribes held power over the Chakchiuma, Tunica, and Yazoo tribes that lived along the Yazoo River, and the Biloxi and Pascagoula tribes of the Gulf Coast. Between 25,000 and 30,000 Indians lived in the Mississippi region when the first European explorers arrived.

Exploration and early settlement. In 1540, the Spanish explorer Hernando de Soto became the first European to enter the Mississippi region. De Soto reached the Mississippi River in 1541 while searching for gold. The Spanish explorers found no treasure in the region and made no settlements there. In 1682, the French explorer Robert Cavelier, Sieur de La Salle, traveled down the Mississippi River from the Great Lakes to the Gulf of Mexico. Cavelier claimed the entire Mississippi Valley for France, and named it *Louisiana* for King Louis XIV. The region included present-day Mississippi.

In 1699, Pierre Le Moyne, Sieur d'Iberville, established the first French settlement of the region at Old Biloxi (now Ocean Springs). In 1716, a second settlement was established by Jean Baptiste Le Moyne, Sieur de Bienville, at Fort Rosalie (now Natchez). Three years later, in 1719, the first black slaves were brought to the region from West Africa. They worked in the rice and tobacco fields of the French colonists.

During the early 1700's, a scheme to develop the Mississippi region was launched by John Law, a Scottish economist. Law's scheme failed, and many people lost the money they had invested in his company. However, Law's venture brought much attention to Louisiana. As a result, thousands of settlers were attracted to the region (see **Mississippi Scheme**). Old Biloxi, New Biloxi (now Biloxi), and Fort Louis de la Mobile (now Mobile, Ala.) served as capital of the region at various times during the early 1700's. In 1722, the French made New Orleans, in present-day Louisiana, the capital of the region. At that time, Louisiana made up a vast territory that extended from the Allegheny Mountains to the Rocky Mountains.



Many difficulties delayed development of the region. At first, the Indians fought the settlers. Later, the British battled the French for possession of the newly settled land. In 1730, the French put down an uprising of the Natchez Indians, nearly wiping out the tribe. But in 1736, British troops helped the Chickasaw Indians defeat the French colonists in the northeastern part of present-day Mississippi. That defeat stopped the French from gaining control of the Mississippi Valley. During the French and Indian War (1754-1763), the British and the Chickasaw kept the French forces in the lower Mississippi Valley from joining the French forces in the Ohio Valley. The Treaty of Paris, signed after the war, gave the British all the land east of the Mississippi River. Thus, the Mississippi region came under British rule. The southern portion became part of the British province called West Florida. Nearly all of the remaining area became part of the Georgia colony.

Territorial days. During the Revolutionary War in America (1775-1783), most of the settlers of West Florida remained loyal to Britain. But the Indians, trappers, and scouts of the rest of the Mississippi region supported the American Colonies. In 1781, because the British were so busy with their war with the colonies, Spain was able to take control of West Florida. Two years later, Britain granted West Florida to Spain. After the British lost the war, the Mississippi region north of about the 32nd parallel was made part of the United States. The area between this boundary and the 31st parallel was claimed by both the United States and Spain. This area included the Natchez district. In 1795, the Spanish government accepted the 31st parallel as the border of the United States in the Pinckney Treaty (see **Pinckney Treaty**).

Congress organized the Mississippi Territory in 1798, with Natchez as the capital. Winthrop Sargent became the first governor of the new territory. It was bounded on the south by the 31st parallel, on the west by the Mississippi River, on the north by a line east from the mouth of the Yazoo River, and on the east by the Chattahoochee River. In 1803, the Louisiana Purchase made the Mississippi River part of the United States. Development of the territory was aided because the river allowed Mississippi trading ships to sail to the Gulf of Mexico.

In 1804, Congress extended the Mississippi Territory north to the border of Tennessee. More land was added in 1812. That year, the part of the West Florida Republic lying east of the Pearl River was incorporated into the

"View of Vicksburg," State of Mississippi Department of Archives and History, Jackson (Hiatt-Ford Photography)

The port of Vicksburg was an important stop for Mississippi riverboats in the 1800's. The city is still a major river port.

Plantations were a center of rural life in the 1800's. This scene shows field hands picking cotton on a plantation along the Mississippi River. A steamboat sails by in the background.

Mississippi Territory. The republic had been formed in 1810 after American settlers took control of the region from Spain. The republic consisted of the land south of the 31st parallel between the Mississippi River and the Perdido River. With the incorporation of this land, the Mississippi Territory extended over all of present-day Alabama and Mississippi.

During the War of 1812, the Choctaw Indians under Chief Pushmataha remained friendly to the Americans. The Choctaw joined the Mississippi militia in helping General Andrew Jackson put down uprisings of the British-supported Creek Indians and in defeating a British army in the Battle of New Orleans.

Statehood. In 1817, Congress divided the Mississippi Territory into the state of Mississippi and the Alabama Territory. On Dec. 10, 1817, Mississippi was admitted to the Union as the 20th state. The first Mississippi state governor, David Holmes, had been territorial governor since 1809. Columbia, Natchez, and Washington served as the state capital at various times until Jackson became the capital in 1822.

In territorial days, Indian tribes had controlled almost two-thirds of Mississippi. The tribes gradually gave up their lands to the U.S. government. By 1832, most of the Indians had moved to the Indian Territory (now Oklahoma). The lands they left were opened for settlement. Many settlers came from the East to farm the fertile soil of Mississippi. Much of the soil was excellent for growing cotton. Cotton production had increased throughout the South as a result of Eli Whitney's cotton gin, which was invented in 1793.

After 1806, an improved type of cottonseed helped increase Mississippi's cotton production. The improved variety was developed from some seeds brought to Mississippi from Mexico. It was called Petit Gulf, the name of the area in Claiborne County where it was developed. The cotton producers used slave labor to operate large cotton plantations. Mississippi became one of the wealthiest states of the period.

During the 1850's, Mississippi farmers built many levees in the Delta region to control the floodwaters of the Mississippi and Yazoo rivers. In 1858, the legislature set up a board of levee commissioners. A large amount of the swampland in the state was drained and made suitable for farming.

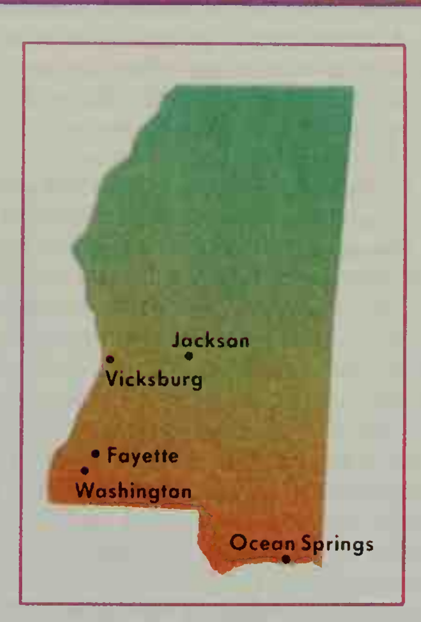
The Civil War and Reconstruction. Most Mississippians did not favor *secession* (withdrawal) from the Union when South Carolina threatened to secede in 1832. But their feelings changed during the next 29 years. The reasons for the change included violations of the Fugitive Slave Law, the struggle over slavery in Kansas, the founding of the Republican Party, and the economic differences between the North and the South. Mississippi became a strong defender of states' rights and of slavery. See **Civil War** (Causes and background of the war).

In January 1861, a convention met in the Old Capitol in Jackson and adopted the Ordinance of Secession. Mississippi became the second state, after South Carolina, to secede from the Union. About five weeks later, Jefferson Davis of Mississippi became president of the Confederacy. He had been a soldier, planter, and a U.S. senator. Davis also had served as secretary of war under President Franklin Pierce.

More than 80,000 Mississippi troops served in the Confederate Army. Union and Confederate forces clashed in many places in Mississippi and on its borders. Important battles were fought at Corinth, Harrisburg (now Tupelo), Holly Springs, Iuka, Jackson, Meridian, and Port Gibson. In June 1864, at Brice's Cross Roads, Confederate General Nathan Bedford Forrest defeated a larger Union cavalry force. Forrest supposedly explained his military successes by saying that he "got there first with the most men."

The Battle of Vicksburg ranks as the most important military action in Mississippi. The Confederate stronghold in Vicksburg fell to General Ulysses S. Grant's Union forces on July 4, 1863, after a 47-day siege. The capture of Vicksburg gave the Union control of the Mississippi River. The Union victories at Vicksburg and Gettysburg marked the turning point of the Civil War.

After the war, in 1867, the United States placed Mississippi under military rule during the Reconstruction period. Mississippi was readmitted to the Union in



Historic Mississippi

The first colonial settlement in the Mississippi Valley was established by Pierre Le Moyne, Sieur d' Iberville, at Old Biloxi (now Ocean Springs) in 1699.

Aaron Burr's preliminary treason trial was held in Washington, Miss., in 1807. Burr had raised a small military force of his own, and was accused of trying to set up a republic in the West.

The Ordinance of Secession was adopted by Mississippi on Jan. 9, 1861, making it the second state to withdraw from the Union.

Vicksburg is often called the Gibraltar of the Confederacy. The South controlled the Mississippi River during the Civil War until Vicksburg finally fell in 1863.

Charles Evers was elected mayor of Fayette in 1969, thus becoming the first black mayor in Mississippi since the Reconstruction period (1865-1877).

WORLD BOOK illustrations by Kevin Chadwick

Important dates in Mississippi

1540 Hernando de Soto entered the Mississippi region.

1699 Pierre Le Moyne, Sieur d'Iberville, established the first French colony at Old Biloxi.

1763 Mississippi became English territory after the French and Indian War.

1781 Spain occupied the Gulf Coast.

1798 The Mississippi Territory was organized.

1817 Mississippi became the 20th state on December 10.

1858 Mississippi started a swamp drainage program in the Delta.

1861 Mississippi seceded from the Union.

1863 Union forces captured Vicksburg in the Civil War.

1870 Mississippi was readmitted to the Union.

1939 Petroleum was discovered at Tinsley.

1954 The Mississippi legislature passed a law banning required union membership.

1960 Mississippi passed laws that broadened the tax-free privilege of industrial properties.

1964 Atomic scientists set off the first nuclear test explosion east of the Mississippi River at Baxterville, Miss.

1969 A federal court ordered the desegregation of Mississippi's public schools.

1969 Charles Evers became the first black mayor in Mississippi since Reconstruction. He was elected in Fayette.

1991 Kirk Fordice became the first Republican to be elected governor of Mississippi since 1874.

1870, after adopting a new state constitution and ratifying Amendments 14 and 15 of the United States Constitution. It took many years for the state to recover from its war losses. After Reconstruction ended in 1876, whites in Mississippi, as in the other Southern states, refused to share political power with blacks. Blacks throughout the South gradually lost most of the rights they had gained after the Civil War. See **Reconstruction**.

The early 1900's were years of progress in industry, agriculture, and education. The construction of railroads provided access to the pine forests of southeast Mississippi, resulting in a boom in the lumber industry. The industry reached a high peak just before World War I began in 1914. New drainage projects in Mississippi opened large swampy areas to agriculture. County agricultural high schools were established in 1908. The state established an illiteracy commission in 1916 to start a special educational program for adults who could not read or write. In 1912, the Mississippi legislature passed laws regulating child labor.

Legislative measures during the 1920's included the establishment of a state commission of education in 1924, of a state library commission in 1926, and of a highway building program in 1929. The first milk condensery in the South opened at Starkville in 1926.

Mississippi suffered greatly in the Mississippi River flood of 1927. About 100,000 people fled from their flooded homes in the Delta. The damage to crops and property in Mississippi totaled over $204 million. The next year, Congress made the U.S. Army Corps of Engineers responsible for controlling floods on the Mississippi River.

Economic development. During the Great Depression of the 1930's, Mississippi launched an important program of economic development. The program, called Balancing Agriculture With Industry (BAWI), was helped by special laws passed by the legislature in 1936. These laws freed new industries from paying certain taxes. The laws also allowed cities and counties to issue bonds and use the bond money to build factories for new industries. The BAWI program is administered by the state's Department of Economic Development. In developing the BAWI program, Mississippi became one of the first states to use national advertising to promote new industries. Mississippi's industrial development was strongly aided by the discovery of petroleum at Tinsley in 1939 and at Vaughan in 1940.

The mid-1900's. During World War II (1939-1945), many war plants operated in Mississippi. The Ingalls shipyards in Pascagoula became an important shipbuilding center. After the war, the state's industrial development continued. In 1954, the legislature passed a right-to-work law. This law provided that no worker has to join a union if he or she does not want to do so. The law became part of the state's Constitution in 1960.

During the 1960's, Mississippi worked to attract new industries. The increasing mechanization of agriculture had created a surplus of farm labor, and Mississippi leaders wanted new industries that could employ former farmworkers. The legislature passed laws in 1960 broadening the tax-free position of industry. In 1963, a huge oil refinery was built in Pascagoula. By 1966, more Mississippians worked in manufacturing than in agriculture. But Mississippi still had relatively little industry compared to many other states, and most of its workers earned low incomes. In 1967, Litton Industries acquired the Ingalls shipyards and began an expansion program in Pascagoula. In other coastal areas, the tourist industry boomed.

Like many other states, Mississippi has had racial problems. The state's Constitution had provided for segregated schools. But in 1954, the Supreme Court of the United States ruled that compulsory segregation of public schools was unconstitutional. Efforts by civil rights groups to bring about integration were sometimes met with violence. In 1962, two people were killed in riots that broke out when James Meredith enrolled as the first black student at the University of Mississippi. In 1963, Medgar Evers, Mississippi field secretary of the National Association for the Advancement of Colored People (NAACP), was shot and killed. In 1964, three civil rights workers were murdered near Philadelphia, Miss. Both white and black leaders in Mississippi spoke out against the violence.

UPI/Bettmann Newsphotos

Medgar Evers, *center,* became the field secretary of the National Association for the Advancement of Colored People (NAACP) in Mississippi in 1954. He worked to help blacks win civil rights until he was shot and killed in 1963.

In the fall of 1964, the first public schools in Mississippi began to desegregate. In 1969, the U.S. Supreme Court ordered an immediate end to all segregated public schools. As a result, a federal court in New Orleans ordered 33 Mississippi school districts to desegregate by December 1969. Many white people opened segregated private schools and enrolled their children. Also in 1969, Charles Evers, brother of Medgar, was elected mayor of Fayette. He became the first black mayor in Mississippi since Reconstruction.

Recent developments. The incomes of Mississippi families rose in the late 1900's. However, these incomes remained low by national standards. New industries moved to the state during this period. The number of Mississippi workers employed in manufacturing grew. But thousands of farmworkers living in the Delta region are jobless because of increased use of machinery on farms.

Today, Mississippi faces the challenge of fully developing its economic program. Local and state government is still organized to meet the needs of an agricultural, rural society and needs to be modernized to deal with economic problems effectively.

University of Mississippi

Farley Hall at the University of Mississippi houses much of the university library's Blues Archive.

Mississippi, University of, is a state-supported coeducational school with campuses in Oxford and Jackson, Miss. The main campus, which is located in Oxford, has a college of liberal arts, a graduate school, and schools of business administration, education, engineering, law, pharmacy, and accountancy. The University of Mississippi Medical Center in Jackson includes schools of dentistry, medicine, nursing, and health-related professions. The university grants bachelor's, master's, and doctor's degrees.

The university's library features materials by and about such Mississippians as the noted authors William Faulkner and Stark Young. Faulkner's Nobel Prize and important manuscripts are kept in the library. The library also includes the Blues Archive. The university owns and maintains Faulkner's home, Rowan Oak, near the main campus. The collections at the University Museums include antique scientific instruments and Greek and Roman coins, pottery, and sculpture.

The university's Center for the Study of Southern Culture promotes education and scholarship on the American South through a wide variety of programs, including annual conferences on Faulkner and on regional history. The federally funded National Center for Physical Acoustics, which conducts research on sound, is located on the Oxford campus and managed by the university.

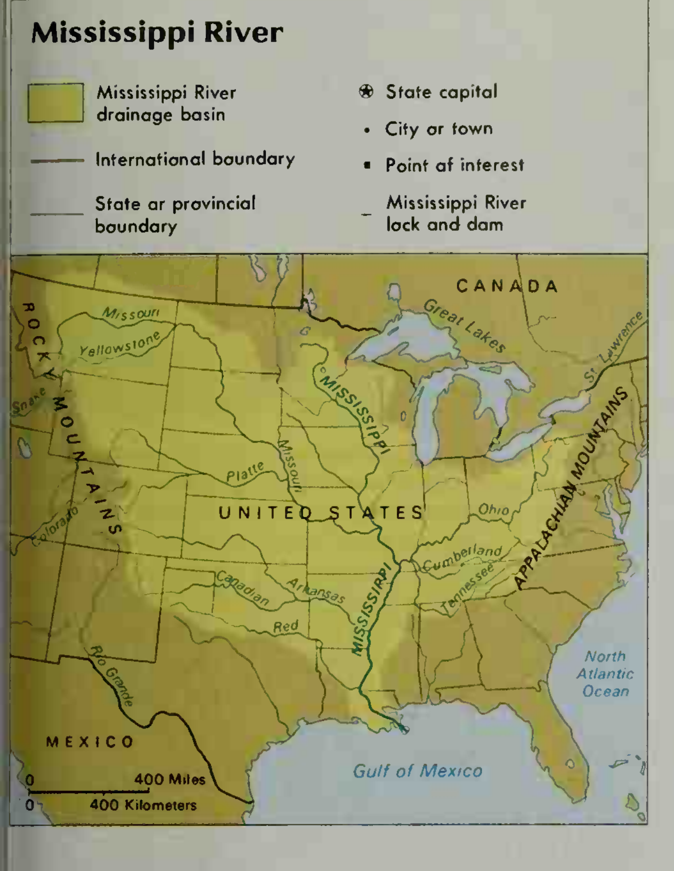
The university was founded in 1844 and opened in 1848. Critically reviewed by the University of Mississippi

Mississippi Bubble. See Mississippi Scheme.

Mississippi River is one of the chief rivers of North America and the second longest river in the United States. Only the Missouri is longer. The Mississippi flows 2,340 miles (3,766 kilometers) from its source in northwestern Minnesota to its mouth in the Gulf of Mexico. The Mississippi and its tributaries drain almost all the plains that lie between the Appalachian Mountains and the Rocky Mountains. This drainage basin covers 1,247,300 square miles (3,230,490 square kilometers) and includes the nation's most productive agricultural and industrial areas.

The Mississippi is the nation's chief inland waterway. It carries agricultural goods, industrial products, and raw materials. Ships can travel the river for more than 1,800 miles (2,897 kilometers) from Minneapolis, Minn., to the Gulf of Mexico. The river ranges in depth from 9 feet (2.7 meters) to 100 feet (30 meters) during most of its course. The river reaches its widest point— about $3\frac{1}{2}$ miles (5.6 kilometers)—just north of Clinton, Iowa, in a backwater formed by Lock and Dam No. 13.

The Mississippi, which is sometimes called "Old Man River," has played a vital role in the history of the United States. During the 1500's and 1600's, it provided a route for Spanish and French explorers. With the coming of steamboats in the 1800's, the Mississippi became a great transportation and trade route. The famous American author Mark Twain described the river vividly in his book *Life on the Mississippi* (1883).



The course of the Mississippi. The Mississippi begins as a small, clear stream that rushes out of Lake Itasca in northwestern Minnesota. The river flows northward and then eastward, linking a series of lakes.

The Mississippi begins to curve southward near Grand Rapids, Minn. As it flows between Minneapolis and St. Paul, Minn., it is joined by the Minnesota River. Beginning with its junction with the St. Croix River, the Mississippi forms part of the boundary between Minnesota and Wisconsin. It is also part of the boundaries of eight other states. Illinois, Kentucky, Tennessee, and Mississippi are to the east, and Iowa, Missouri, Arkansas, and part of Louisiana are on the western shore.

Two major tributaries, the Illinois River and the Missouri River, join the Mississippi above St. Louis. The muddy waters of the Missouri mix with the clear waters of the Mississippi, and the Mississippi takes on the muddy color for which it is known in the South.

The Ohio River flows into the Mississippi at Cairo, Ill., doubling the Mississippi's volume of water. This junction divides the upper Mississippi from the lower Mississippi. South of Cairo, the flood plain of the Mississippi forms a fertile valley. The valley is over 50 miles (80 kilometers) wide in some places. The river winds back and forth through this valley and forms broad loops. It sometimes changes its course and cuts off the loops, creating horseshoe-shaped lakes called *oxbow lakes*. Along its lower course, the Mississippi deposits soil particles called *silt* along its banks. The silt builds up and forms embankments known as *natural levees*.

The Arkansas River joins the Mississippi about 50 miles (80 kilometers) north of Greenville, Miss. North of Marksville, La., the Red River enters the Mississippi flood plain, but most of its flow continues into the Atchafalaya River. About a fourth of the Mississippi's water also goes into the Atchafalaya.

WORLD BOOK maps

As the Mississippi approaches the Gulf of Mexico, it deposits large amounts of silt to form a delta. The Mississippi Delta covers about 13,000 square miles (33,700 square kilometers). South of New Orleans, the river breaks up into several channels called *distributaries,* which enter the Gulf of Mexico. They include Main Pass, North Pass, South Pass, and Southwest Pass. The Mississippi River system empties over 640, 000 cubic feet (18,100 cubic meters) of water per second into the gulf. This discharge totals about 133 cubic miles (554 cubic kilometers) of water per year.

Commerce. The Mississippi River carries about 60 percent of the freight that is transported on the nation's inland waterways. About 460 million short tons (420 million metric tons) of freight are transported on the Mississippi annually.

Most commercial freight on the Mississippi travels on large barges pushed by tugboats. Between Minneapolis and Cairo, the southbound freight consists mainly of agricultural products, such as corn, soybeans, and wheat. Coal and steel products from the Ohio River system are transported north. South of Cairo, goods from the Ohio double the Mississippi's traffic. Most of the cargo consists of southbound agricultural goods, coal, and steel products. At Baton Rouge, La., petrochemical products, aluminum, and petroleum are added to the barge traffic. Beginning at Baton Rouge, the Mississippi deepens and allows passage of oceangoing vessels. The greatest volume of traffic on the Mississippi moves between New Orleans and Southwest Pass.

Floods and flood control. From time to time, the Mississippi has caused serious floods. The floods occur when rain and melting snow bring unusually large amounts of water into the Mississippi. The river then

Milt and Joan Mann

The source of the Mississippi River is Lake Itasca in northwestern Minnesota. The Mississippi begins as a small, clear stream but it later reaches a width of about $3\frac{1}{2}$ miles (5.6 kilometers) in a backwater north of Clinton, Iowa.

overflows into the surrounding flood plain. Especially destructive floods occurred in 1927, 1937, 1965, 1973, 1982, 1983, and 1993. The most destructive of these was the 1993 flood. See **Flood.**

Dams and levees have provided some protection against flooding by the Mississippi River. A series of dams along the Missouri and Ohio rivers control the amount of water that enters the Mississippi. The Mississippi itself was dammed north of St. Louis. Along the lower course of the Mississippi, the natural levees have been heightened and new levees built to prevent flooding. Dredging of the river channel not only increases the amount of water the river can carry, but also aids navigation on the river. In addition, areas of land that are called *floodways* provide outlets for draining off water when the river reaches flood level.

Animal and plant life. The Mississippi River and its valley support many kinds of animals and plants. Such freshwater fishes as bass, sunfish, and trout live in the clear waters of the upper Mississippi. Carp, catfish, and buffalo fish are found in the muddy waters of the lower Mississippi.

The most common animals in the Mississippi Valley are mink, muskrats, opossums, otters, and skunks. Large rodents called *nutrias* live in the swamps and marshlands of the delta area (see **Nutria**). This area also provides winter nesting grounds for ducks, geese, and other migratory birds. Pelicans, herons, and egrets live in the area throughout the year.

Forests of hardwood trees, such as basswood, hickory, maple, and oak, grow in the upper Mississippi Valley. South of Cairo, the forests consist mainly of baldcypress, sweet gum, southern oak, and tupelo trees.

Pollution seriously threatens the wildlife of the Mississippi. Fertilizers and insecticides used on farms are washed into the river, and industries empty wastes into its waters. Since the 1970's, steps have been taken to prevent further pollution of the river. For example, federal regulations prohibit farmers from using certain insecticides and other harmful chemicals.

History. The Mississippi was formed about 2 million years ago at the beginning of the Pleistocene Ice Age. During this period, glaciers covered much of the Northern Hemisphere. Melting ice from the glaciers was carried to the Mississippi by both the Missouri and Ohio rivers.

Various Indian tribes, including the Illinois, the Kickapoo, the Ojibway, and the Santee Dakota, lived in the upper Mississippi Valley. The name *Mississippi,* which means *big river,* came from these tribes. The lower valley was the home of such tribes as the Chickasaw, the Choctaw, the Natchez, and the Tunica.

The first European to travel on the Mississippi was

Robert H. Glaze, Artstreet

Along the upper course of the Mississippi, forests of hardwood trees and steep bluffs line the river's banks in many areas. The river often cuts off areas of land, creating islands.

Robert H. Glaze, Artstreet

The port of New Orleans, on the Mississippi River, is the busiest port in the United States. Ships from all parts of the world dock at the wharves along the Mississippi.

U.S. Army Corps of Engineers

Southwest Pass, a channel of the Mississippi, flows into the Gulf of Mexico. The greatest volume of traffic on the Mississippi moves between New Orleans and Southwest Pass.

the Spanish explorer Hernando de Soto. He crossed the river in 1541 near what is now Memphis. In the early 1680's, the French explorer Sieur de La Salle traveled on the river and claimed the Mississippi Valley for France.

France lost all of its territories on the mainland of North America as a result of the French and Indian War (1754-1763). Britain gained the land east of the Mississippi, and Spain took over the land west of the river. After the Revolutionary War in America (1775-1783), the United States took control of the British territories. In 1800, France regained the land west of the Mississippi. The United States bought this land from France in the Louisiana Purchase of 1803.

After the entire Mississippi Valley became part of the United States, settlers and traders set out on the river in flatboats, keelboats, and rafts. The importance of the river as a transportation and trade route increased with the development of steamboats in the early 1800's. Mississippi River cities, including St. Louis, Memphis, and New Orleans, served as supply centers for the westward movement.

During the American Civil War (1861-1865), the Mississippi served as an invasion route for the Union forces. The capture of such river cities as New Orleans, Memphis, and Vicksburg, Mississippi, divided the Confederacy in half and assured victory for the North. After the war, railroads soon took over most of the river's former steamboat traffic. The completion of the Eads Bridge in 1874, connecting St. Louis and East St. Louis, Illinois, provided a major rail crossing over the river. Many more bridges were built during the years that followed.

The importance of the Mississippi as a transportation route has increased greatly since the 1920's. No other means of transportation can move masses of heavy, bulky cargo as cheaply as the barges and tugboats on the mighty river. John Edwin Coffman

Mississippi Scheme was a wild financial project formulated in France in 1717. John Law, a Scottish economist, originated the scheme, which resulted in the organization of a business firm called the Mississippi Company. The French *regent* (temporary ruler), Philippe, Duke of Orléans, gave the company a *monopoly* (exclusive rights) to carry on far-reaching business operations in French-held Louisiana and Canada. At first, the scheme won widespread approval. Thousands of French people bought shares in Law's company without really knowing how their money was to be used. But when the stockholders discovered that the company actually did little to develop business enterprises in America, they became frightened and began to sell their shares at greatly reduced prices. The result was a financial panic in 1720, known as the bursting of "The Mississippi Bubble." A few investors who sold their shares early at high prices made huge profits. But others suffered heavy losses. The scheme failed, but it helped advertise Louisiana and brought thousands of settlers and slaves to the colony. Maarten Ultee

Mississippi State University is a coeducational school in Mississippi State, Mississippi. It receives state and federal support. It has colleges of agriculture, arts and sciences, business and industry, education, engineering, and veterinary medicine; schools of accountancy, architecture, and forest resources; and a graduate school. Courses lead to bachelor's, master's, and doctor's degrees. The university includes an agricultural and forestry experiment station, an agricultural extension service, a boll weevil research laboratory, and a chemical regulatory laboratory. It is noted for its aerospace research facilities and a seed technology laboratory. The school was founded in 1878 and took its present name in 1958. Critically reviewed by Mississippi State University

Mississippi University for Women is a state-controlled coeducational school in Columbus, Mississippi. Founded in 1884, it was the first public college for women in the United States. The university became coeducational in 1982. Its undergraduate curriculum emphasizes liberal arts and professional preparation programs. Master's degrees are available in education and nursing. The university also houses the Mississippi School for Mathematics and Science, a residential high school for gifted students.

Missoula, *muh ZOO luh* (pop. 57,053), is one of the largest cities in Montana. It lies in the west-central part of the state, on the Pacific slope of the Rocky Mountains (see Montana [political map]).

Missoula's main industries are the production of wood and paper products. The city is the site of the University of Montana. It also serves as the headquarters of Region One of the United States Forest Service. Nearby is a training center for Forest Service firefighters. North of Missoula is the Rattlesnake National Recreation Area and Wilderness, which covers about 61,000 acres (25,000 hectares).

The name *Missoula* comes from a Flathead Indian word meaning *by or near the cold, chilling waters.* The word might refer to Hell Gate Canyon, just east of Missoula, where Blackfeet Indians ambushed Flathead Indians. Missoula was founded in 1860. It has a mayor-council government. Bradley Hurd

Missouri *The Show Me State*

Missouri, *muh ZOOR ee* or *muh ZOOR uh,* is an important industrial and farming state of the Midwest region of the United States. Its location and its two great rivers have made Missouri a center of water, land, and air transportation.

The mighty Mississippi River forms Missouri's eastern border. The wide Missouri River winds across the state from west to east. A wealth of food, manufactured products, and raw materials is shipped on these waterways—the nation's longest rivers. Kansas City and St. Louis rank among the chief U.S. air and rail terminals. They also are among the nation's top trucking centers. Several major railroad lines cross the state, including three that carry Amtrak passenger trains. Major highways, including five interstate highways, also crisscross Missouri.

Vast fields of golden grain and green grasses cover the rolling plains in the north and west. Swift streams tumble through the wooded plateau of southern Missouri. This scenic region, called the Ozarks, is one of the major recreation areas of the Midwest.

Most of Missouri's workers are employed in service industries, which include government, health care, and retail trade. The state's factories turn out large numbers of airplanes and automobiles. Some manufacturing activities, such as meat packing and fertilizer production, are related to Missouri's huge farm output. Missouri ranks among the leading producers of beef cattle, hogs, and soybeans.

Missouri is sometimes called the *Mother of the West* because it once lay at the frontier of the United States. The state supplied many of the pioneers who settled the vast region between Missouri and the Pacific Ocean. St. Louis, St. Charles, Independence, St. Joseph, and Westport Landing (now Kansas City) served as jumping-off places for the westbound pioneers. The historic Santa Fe Trail led from Independence to the rich, faraway Southwest. Thousands of settlers also followed the Oregon Trail from Independence to the Pacific Northwest. Furs brought from the Northwest made St. Louis the fur capital of the world.

During the American Civil War (1861-1865), Missourians were torn between loyalties to the South and to the Union. After the war, manufacturing developed rapidly,

Interesting facts about Missouri

WORLD BOOK illustrations by Kevin Chadwick

The world's first school of journalism opened at the University of Missouri at Columbia in 1908.

The first parachute jump from an airplane was made March 1, 1912, by Captain Albert Berry at Jefferson Barracks, St. Louis. He jumped from an altitude of 1,500 feet (460 meters). His parachute was a modified hot-air balloon.

First parachute jump

The first public school kindergarten was opened in 1873 by the St. Louis Board of Education. Susan Elizabeth Blow taught the class of 68 students.

The world's largest producer of corncob pipes is Washington, Mo. Factories there make about 6 million corncob pipes each year.

Ice cream cones were first served at the 1904 Louisiana Purchase Exposition world's fair in St. Louis.

Ice cream cones

and St. Louis and Kansas City grew into industrial giants. Agriculture also expanded, and Missouri became a great farming state.

Many outstanding Americans have lived in Missouri. They include Harry S. Truman, the 33rd President of the United States; Mark Twain, the creator of Tom Sawyer and Huckleberry Finn; Walt Disney, the famous motion-picture producer; Eugene Field, the beloved children's poet; George Washington Carver, the great scientist; Joseph Pulitzer, the famous journalist; Scott Joplin, a ragtime music composer; General John J. Pershing and General Omar N. Bradley, military commanders; and Thomas Hart Benton and George Caleb Bingham, noted painters.

The state's name comes from the Missouri River. The word *Missouri* probably came from an Indian word meaning the *town of the large canoes.* Missouri's nickname is the Show Me State. This nickname is usually traced to a speech by Congressman Willard Duncan Vandiver of Missouri in 1899. Speaking in Philadelphia, Vandiver said: ". . . frothy eloquence neither convinces nor satisfies me. I am from Missouri. You have got to show me."

Jefferson City is Missouri's capital, and Kansas City is the largest city.

Farmers harvest corn from the rich, fertile soil of Missouri's plains region. Fields of grain or green grasses cover most of northern Missouri. It is a leading corn-producing state.

Missouri in brief

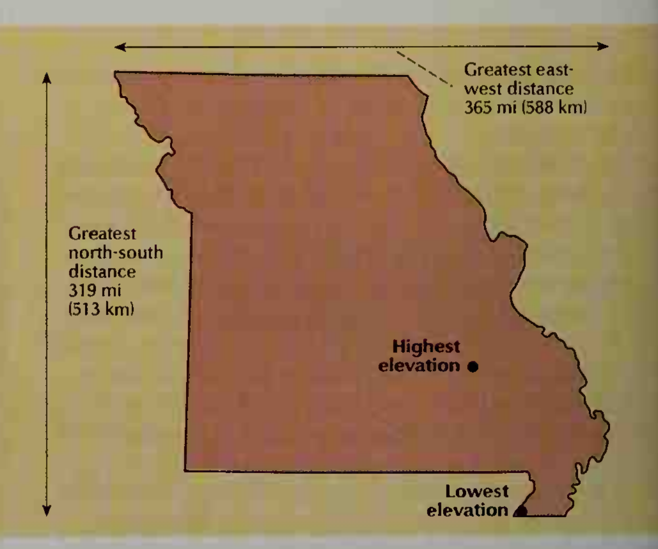
Symbols of Missouri

The state flag, adopted in 1913, has stripes of red, white, and blue that symbolize loyalty to the Union as well as valor, purity, vigilance, and justice. The coat of arms in the center is surrounded by a ring of 24 stars, which show that Missouri was the 24th state. On the state seal, adopted in 1822, two grizzly bears support a shield featuring symbols of Missouri on the left and the arms of the United States on the right. The bears represent the state's strength and the bravery of its citizens.

State flag

State seal

Missouri (brown) ranks 19th in size among all the states and 6th in size among the Midwestern States (yellow).



The State Capitol is in Jefferson City, Missouri's capital since 1826. Earlier capitals were St. Louis (1820) and St. Charles (1821-1826).

General information

Statehood: Aug. 10, 1821, the 24th state.
State abbreviations: Mo. (traditional); MO (postal).
State motto: *Salus Populi Suprema Lex Esto* (The Welfare of the People Shall Be the Supreme Law).
State song: "Missouri Waltz." Words by J. R. Shannon; music from a melody obtained from John V. Eppel.

Land and climate

Area: 69,709 mi² (180,546 km²), including 811 mi² (2,100 km²) of inland water.
Elevation: *Highest*—Taum Sauk Mountain, 1,772 ft (540 m) above sea level. *Lowest*—230 ft (70 m) above sea level, along the St. Francis River near Cardwell.
Record high temperature: 118 °F (48 °C) at Clinton on July 15, 1936, at Lamar on July 18, 1936, and at Union and Warsaw on July 14, 1954.
Record low temperature: −40 °F (−40 °C) at Warsaw on Feb. 13, 1905.
Average July temperature: 78 °F (26 °C).
Average January temperature: 30 °F (−1 °C).
Average yearly precipitation: 40 in (102 cm).

Important dates

1682 La Salle claimed the Mississippi Valley, including Missouri, for France.

1764 Pierre Laclède Liguest and René Auguste Chouteau established St. Louis.

1812 Congress made Missouri a territory.

1821 Missouri became the 24th state on August 10.

1854 Border warfare began between antislavery Kansans and proslavery Missourians.

People

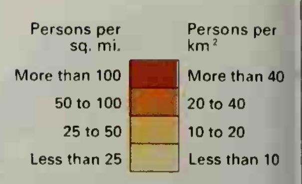
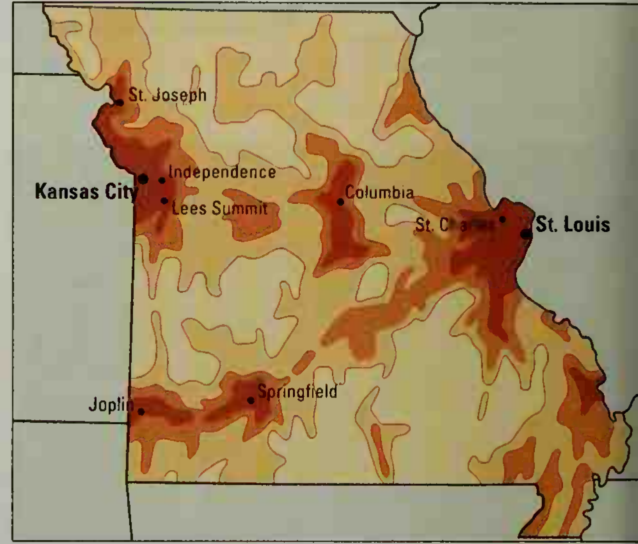
Population. The 2000 United States census reported that Missouri had 5,595,211 people. The state's population had increased about 9 percent over the 1990 census figure, 5,117,073. According to the 2000 census, Missouri ranks 17th in population among the 50 states.

About two-thirds of the people in Missouri live in one of the state's six metropolitan areas (see **Metropolitan area**). The largest one is the St. Louis area, which extends into Illinois and has a population of more than 2 $\frac{1}{2}$ million. Other metropolitan areas in Missouri are Columbia, Joplin, Kansas City, St. Joseph, and Springfield. For the populations of these metropolitan areas, see the *Index* to the political map of Missouri.



Kansas City is the state's largest city, and St. Louis ranks second. They rank among the nation's chief transportation, grain, and livestock centers. Other important cities include Springfield, Independence, and Columbia.



About 11 percent of the people living in Missouri are African Americans. Other large population groups in the state include people who are of German, Irish, English, American Indian, French, Italian, Dutch, and Scotch-Irish descent.

Schools. Missouri's first school was a private elementary school established in St. Louis in 1774. In 1820, Missouri's first constitution included a provision for establishing a system of public education. The system did not start operating until 1839, however.

Population density

More than two-thirds of Missouri's people live in metropolitan areas. Kansas City and St. Louis are the state's largest urban areas.

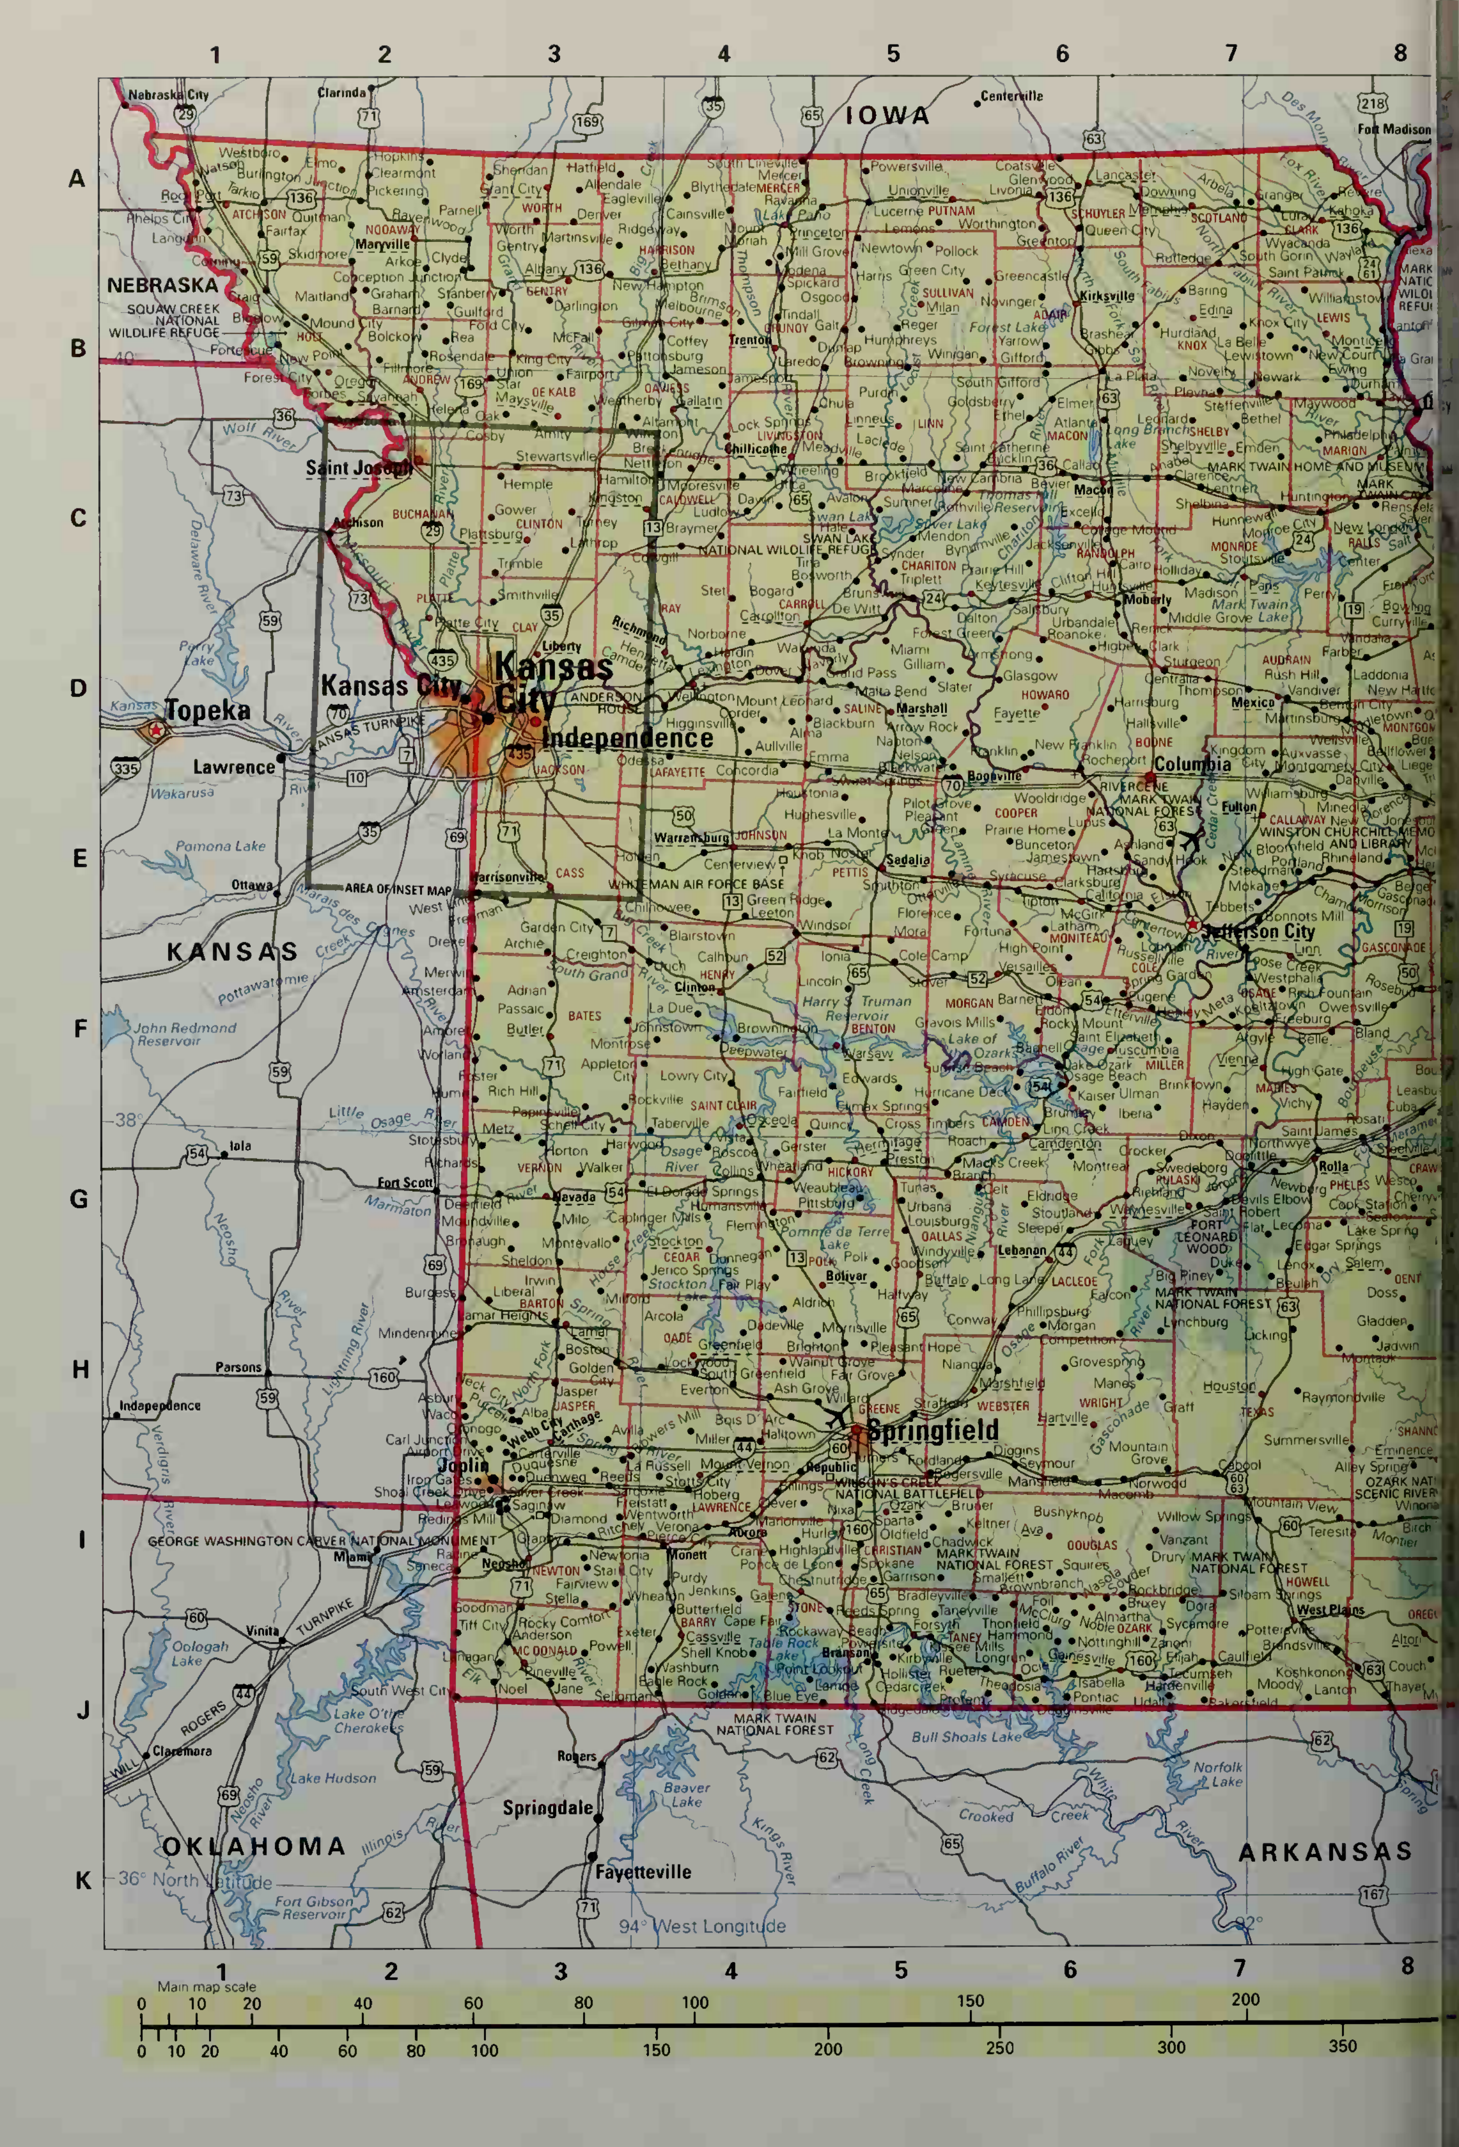
The State Board of Education supervises Missouri's public school system. The Board of Education has eight members appointed by the governor to eight-year terms. One term expires each year. The board appoints a commissioner of education, who serves as the chief administrative officer of the Department of Elementary and Secondary Education. All children from the ages of 7 through 15 must attend school. For the number of students and teachers in Missouri, see **Education** (table).

Libraries. Many Missouri public libraries grew out of public school libraries. Some started as *subscription libraries,* in which members contributed money and used books for free. The St. Louis Public Library was founded in 1865. It was supported by school board funds and by fees and donations. It became tax-supported in 1893.

Today, Missouri has about 350 public libraries and about 70 college and university libraries. Its largest library is at the University of Missouri at Columbia.



Museums. The St. Louis Art Museum has a collection from many countries and periods. The Nelson-Atkins Museum of Art in Kansas City owns noted collections of Asian and American art. The Capitol in Jefferson City houses a museum that has collections of Missouri materials. These materials have historical, geological, scientific, and cultural interest. The Missouri History Museum in Forest Park in St. Louis displays trophies and gifts received by Charles A. Lindbergh, the aviator. The Harry S. Truman Library in Independence exhibits the souvenirs of the 33rd president. The St. Louis Science Center features displays on computers, architecture, and the environment.

Visitor's guide

Missouri's mild climate and many attractions make the state a popular vacationland. Visitors enjoy the state's abundant wildlife, rugged hills, rushing streams, scenic lakes, and peaceful woodlands. People who like to fish can try their luck for bass, trout, and other fish in clear, spring-fed waters. Other attractions include natural wonders, such as great bubbling springs and deep caverns.

Missouri's cities and towns offer a variety of entertainment and many historical and educational sights, including theme parks, musical performances, zoos, and science centers. One of Missouri's best-known annual events is the Fair St. Louis. It is held in early July in St. Louis and features concerts, air shows, ethnic food, and Independence Day fireworks.

Broom making in Silver Dollar City

Places to visit

Following are brief descriptions of some of Missouri's many interesting places to visit:

Branson, a town in the southwest Missouri Ozarks with more than 40 theaters, offers live musical performances by major artists. It also features theme parks. Millions of people visit Branson each year.

Gateway Arch, in St. Louis, commemorates the city's role in the settlement of the West. The arch rises 630 feet (192 meters) and ranks as the tallest monument constructed in the United States. Small trains carry visitors to the top.

Harry S. Truman Library, in Independence, opened in 1957. The building houses over 3 million documents and mementos of Truman's presidency.

Lake of the Ozarks, in central Missouri, is one of the largest artificially created lakes in the world. Its shoreline is more than 1,300 miles (2,090 kilometers) long. The lake and the areas around it form a popular resort and recreation center.

Mark Twain Cave, near Hannibal, is a cave that Mark Twain learned about as a boy. In *The Adventures of Tom Sawyer,* Tom and his friend Becky Thatcher get lost in this cave.

Mark Twain home, in Hannibal, is the restored boyhood home of the writer. An adjacent museum has many objects connected with Mark Twain's life. A second museum houses Norman Rockwell paintings.

Meramec Caverns, near Sullivan, is a legendary hideout of the outlaw Jesse James. The first room of this huge cave is large enough to hold 300 automobiles.

Pony Express Stables, in St. Joseph, are preserved to help trace the heritage of the famed Pony Express. Express riders carried United States mail between St. Joseph and Sacramento, California, from April 1860 to October 1861.

Silver Dollar City, near Branson, is a reconstruction of an 1890's American mining town. Craftworkers show how Conestoga wagons were built and demonstrate various pioneer crafts.

Winston Churchill Memorial and Library, in Fulton, was formerly the Church of St. Mary Aldermanbury. It was dismantled and moved from London after World War II, and rebuilt at Westminster College. Winston Churchill delivered his famous "iron curtain" speech on the campus in 1946.

National forest and parklands. Mark Twain National Forest lies in the southern part of the state. Ulysses S. Grant National Historic Site, near St. Louis, is the estate occupied by Grant in the years immediately preceding the Civil War. George Washington Carver National Monument, near Diamond, honors the famous Missouri-born scientist. For more information on these and other national parklands in Missouri, see the map and tables in the *World Book* article on National Park System.

State parks and conservation areas. Missouri has 46 state parks and 33 state historic sites. For information about the state park system, write to Director, Division of State Parks, P.O. Box 176, Jefferson City, MO 65102. The Missouri Department of Conservation owns and manages more than 800 conservation areas, including forests, uplands, wetlands, and over 600 lakes. For information, write to Director, Department of Conservation, P.O. Box 180, Jefferson City, MO 65102.

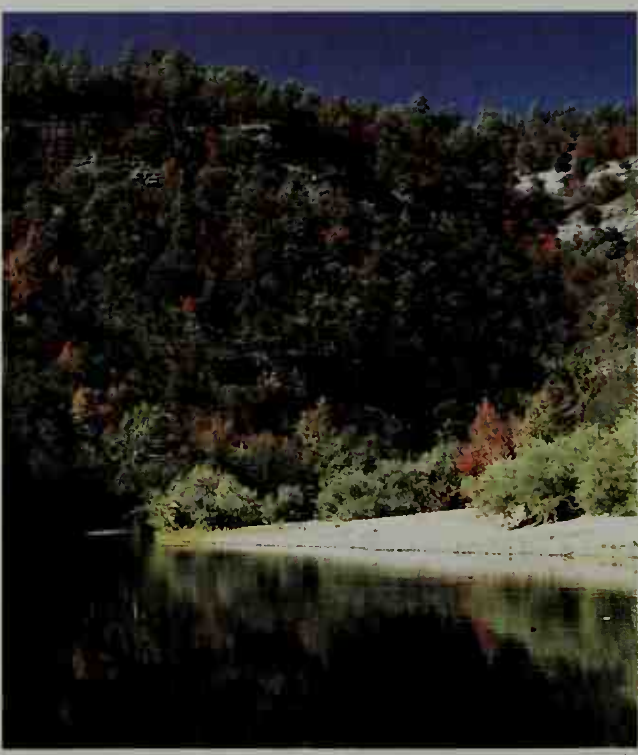
Land and climate

Land regions. Missouri has four main land regions. These are, from north to south: (1) the Dissected Till Plains, (2) the Osage Plains, (3) the Ozark Plateau (or Ozarks), and (4) the Mississippi Alluvial Plain.

The Dissected Till Plains lie north of the Missouri River. Glaciers once covered this region. The great ice sheets left a rich, deep deposit of soil-forming materials especially suited to the growing of corn. Many slow-moving streams drain the rolling surface of this land region.

The Osage Plains lie in western Missouri. This is a region of flat prairie land, broken in places by low hills. Glacial ice never covered the region, and the soil is not as rich as that of the Dissected Till Plains. The chief crops are corn and other grains.

The Ozark Plateau is the state's largest land region. Forested hills and low mountains give it scenic beauty. The plateau rises from 500 to 1,700 feet (150 to 518 meters) or more above sea level. In the extreme southwestern corner of the state, a high, wooded tableland has soil especially good for gardening and raising strawberries. The river valleys are about the only level land in the Ozark region. The plateau is one of the nation's major tourist areas because of its many caves, large springs and lakes, and clear, fast-flowing streams.



The St. Francois Mountains rise in the southeast. This series of granite peaks, knobs, and domes covers about 70 square miles (180 square kilometers). The St. Francois Mountains do not form a continuous range. They rise more or less in groups, usually of two or three peaks. The St. Francois Mountains make up the highest and most rugged part of the state. One of the peaks, Taum Sauk (1,772 feet, or 540 meters), is the highest point in Missouri.

The Mississippi Alluvial Plain covers the southeastern corner of Missouri. This region was once a swampy wilderness. Much of the area has been cleared and drained, and the soil is unusually rich for farming. Cotton, soybeans, and rice are important crops. The southern part of the plain is known as the *Boot Heel* because of its shape.

Rivers and lakes. Missouri owes much of its commercial and industrial importance to the two largest rivers in the United States—the Mississippi and the Missouri. These rivers and their branches provide water highways for transportation, water supplies for cities and industries, and hydroelectric power for homes and factories.

The Current River is one of Missouri's most beautiful rivers. It starts from Montauk Spring in the Ozarks, which has a daily flow of about 40 million gallons (150 million liters). The river's name comes from the swift flow of its cold, sparkling waters. Like the Black, James, St. Francis, and other rivers of the Ozark Plateau, the Current is noted for its game fish. Other rivers favored by fishermen include the Gasconade, Little Piney, Meramec, and White.

The Harry S. Truman Reservoir, an artificially created lake, is the largest lake in the state. The reservoir covers about 55,600 acres (22,500 hectares). The second largest lake is Lake of the Ozarks. It covers about 55,300 acres

© Robert M. Lindholm

A colorful, tree-covered cliff is reflected in a pool of an Ozark stream. The Ozark Plateau region of southern Missouri has some of the most beautiful wilderness in the United States.

(22,400 hectares). Lake of the Ozarks was also artificially created. Other artificially created lakes include Pomme de Terre, Table Rock, and Taneycomo.

Springs and caves. About 10,000 springs bubble from the ground in the Ozark Plateau. More than a hundred springs have a daily water flow of over 1 million gallons (3.8 million liters) each. The largest is Big Spring, near Van Buren. It has an average flow of about 278 million gallons (1,052 million liters) of water a day. Missouri also has about 30 mineral springs.

More than 1,450 caves have been found in Missouri. Underground streams formed these caves beneath the Ozarks. One of the largest caves, Marvel Cave, is near Branson. The cave has 10 miles (16 kilometers) of passageways. Every year, about 20 marriages are performed in Bridal Cave, near Camdenton.

Plant and animal life. Forests cover about a third of Missouri, chiefly the southern part of the state. The state's forests are made up largely of hardwoods. Most of the forests consist of various types of oak or hickory. The state also has large growths of such trees as ash, bald cypress, cottonwood, elm, maple, shortleaf pine, and sweet gum.

Asters, dogwood, goldenrod, milkweed, roses, sweet Williams, verbenas, violets, and many kinds of mint and hawthorn grow throughout Missouri. Prairie blossoms include anemones, meadow roses, turtleheads, and white snakeroots. Mistletoe grows on many trees on the Mississippi Alluvial Plain region of Missouri. The Ozark Plateau probably has more flowers than any other region in the state.

White-tailed deer are the most numerous of Missouri's big-game animals. Other animals include beavers, cottontail rabbits, foxes, muskrats, opossums, raccoons, skunks, and squirrels. The most common birds are the blue jay, cardinal, mockingbird, purple finch, and woodpecker. Baltimore orioles, goldfinch, and whippoorwills are also seen.

The bobwhite quail is Missouri's most plentiful game bird. Fish found in Missouri's lakes, rivers, and streams include bass, bluegills, catfish, crappies, jack salmon, and trout.

Climate. Winters and summers are milder in the mountain areas of Missouri than in the lower-lying plains. In July, the average temperature is about 78° F. (26° C). The state's record high temperature is 118° F. (48° C). It was set at Clinton on July 15, 1936; at Lamar on July 18, 1936; and at Union and Warsaw on July 14, 1954.

The average January temperature is about 30° F. (−1° C). Missouri's record low temperature of −40° F. (−40° C) was set at Warsaw on Feb. 13, 1905. The average yearly *precipitation* (rain, melted snow, and other forms of moisture) ranges from about 50 inches (130 centimeters) in the southeast to 30 inches (76 centimeters) in the northwest. The growing season in Missouri ranges from 225 days in the southeastern part of the state to 170 days in the northern part.

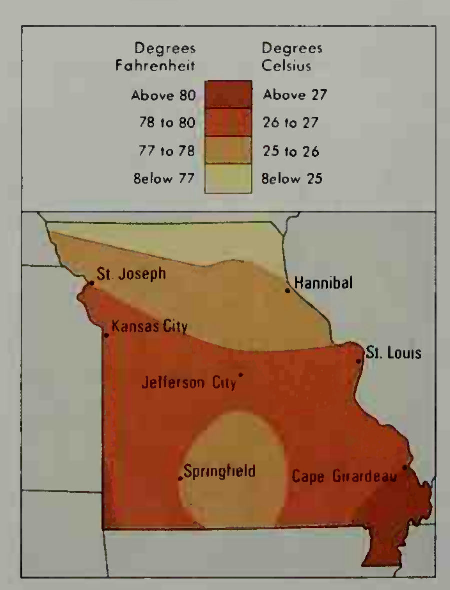
Average January temperatures

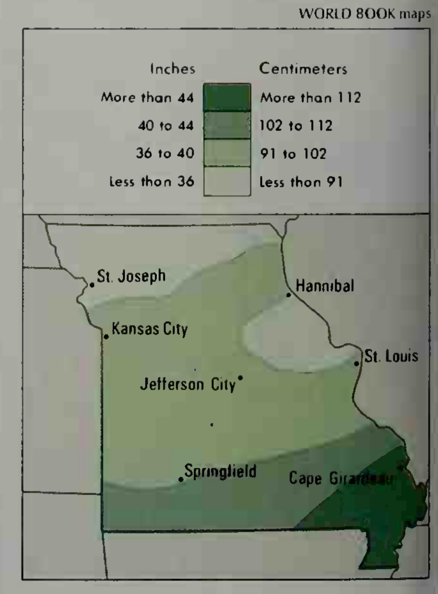


Missouri has a broad range of winter temperatures. The north is the coldest while the south averages above freezing.

Degrees Fahrenheit / Degrees Celsius
Above 32 / Above 0
28 to 32 / -2 to 0
24 to 28 / -4 to -2
Below 24 / Below -4

St Joseph, Hannibal, Kansas City, St. Louis, Jefferson City, Springfield, Cape Girardeau

Average July temperatures



Summers in Missouri are milder in the mountainous south than in the lower-lying plains. The far north is also milder.

Average yearly precipitation

Precipitation varies widely in the state, with the southeast getting the most. The northern part of Missouri is the driest.

WORLD BOOK maps

Missouri's variety—great and small rivers, big cities and rural communities—provides strength for its economy. Its important manufacturing and service industries are centered around cities, such as St. Louis and Kansas City. The state is also known for its natural resources—rich soil, valuable minerals, and scenic waterways.

Natural resources of Missouri include fertile soils and large mineral deposits.

Soil. The soils of the Dissected Till Plains are mainly glacial soils (clay mixed with sand and gravel) and *loess* (a fine-grained topsoil). A band of rich loess, often more than 50 feet (15 meters) deep, lies along the Missouri River. The Osage Plains have soils of medium fertility, ranging from dark brown loam to lighter colored sandy or silt loams.

Brown limestone soils cover most of the southwestern part of the Ozarks. Elsewhere in the Ozarks, the soils are shallow and stony. The Mississippi River has deposited rich soils on the Mississippi Alluvial Plain. Rich alluvial soil also lies along the Missouri River.

Minerals. The state's most important metal is lead. Lead is found in Iron, Reynolds, and Washington counties. Copper, silver, and zinc are also recovered by processing the lead ore. Large fire clay deposits occur in east-central Missouri. An important reserve of barite, a barium ore, lies south of St. Louis. Limestone, Missouri's leading quarry product, is found in most of the state. Dolomite, granite, marble, and sandstone are also quarried. Coal is found in about half of the state, in an area extending from the southwest to the northeast. Missouri's coal reserves total about 6 billion tons (5.4 billion metric tons). The state has deposits of iron ore in the eastern Ozarks. Missouri also has small amounts of oil and natural gas along its western border. Other mined products found in the state include cobalt, manganese, nickel, sand and gravel, and tungsten.

Service industries account for the greatest portion of Missouri's *gross state product*—the total value of all goods and services produced in a state in a year. Most of the service industries are concentrated in the state's metropolitan areas.

The community, business, and personal services group is the leading service industry group in Missouri in terms of the gross state product. It is also the state's leading employer. This service group includes such businesses as private health care, hotels, data processing services, and professional sports franchises. Kansas City and St. Louis are the leading areas for most of these activities. Columbia, Kansas City, and Springfield are also major centers of health care in Missouri. Professional sports teams in Kansas City and St. Louis make an important contribution to the state's economy.

Wholesale and retail trade ranks second among Missouri's service industries. The wholesale trade of farm products is important in Kansas City, St. Joseph, St. Louis, and Springfield. St. Louis is a major national center for the wholesale trade of automobiles. The wholesale trade of groceries is significant in all of Missouri's urban areas. Leading retail establishments include automobile dealerships, department stores, and restaurants. The St. Louis and Kansas City areas are the leaders in retail trade in Missouri.

Finance, insurance, and real estate is the third most important service industry in Missouri in terms of the gross state product. St. Louis and Kansas City are both among the Midwest's leading financial cities. Each city is

Production and workers by economic activities

McDonnell Douglas Corp.

Airplane manufacturing is a major industry in the St. Louis area. The factory shown here is producing F-15 Eagle fighter planes.

the home of a district branch of the Federal Reserve Bank. The largest commercial banks and insurance companies in Missouri are located in St. Louis.

Government ranks fourth among the state's service industries. Government services include the operation of public schools, public hospitals, and military bases.

Transportation, communication, and utilities form Missouri's fifth-ranking service industry. Transportation services are important to Missouri's economy. A major moving company is headquartered in Fenton. Many railroads have large operations in Kansas City and St. Louis. Some firms use barges on the Mississippi and Missouri rivers to transport freight. Telephone companies form the largest part of the communications sector. More information about transportation and communication can be found later in this section.

Manufacturing. Goods made in Missouri have a *value added by manufacture* of more than $45 billion a year. This figure represents the increase in value of raw materials after they become finished products. Most of the state's 7,500-plus factories are located in the Kansas City and St. Louis metropolitan areas.

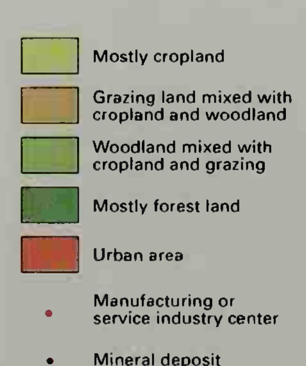
The production of transportation equipment is Missouri's leading manufacturing activity by far. Factories produce airplanes, barges, railroad cars, truck and bus bodies, and truck trailers. Missouri ranks as a leading state in automobile and truck production. Fenton, Kansas City, and Wentzville have automobile plants. Claycomo and Fenton manufacture trucks. St. Louis is one of the leading areas in the United States for the production of military aircraft. Factories in northern St. Louis County manufacture F-15 Eagle and F-18 Hornet supersonic fighter planes.

Chemicals rank second among Missouri's manufactured products. This industry includes the production of fertilizer, insecticide, paint, pharmaceuticals, and soap. The St. Louis area accounts for about half of the state's total chemical manufacturing.

Food products rank third in terms of value added by manufacture. One of the nation's largest dairy-processing plants is in Springfield. St. Louis ranks as a leading beer-brewing center of the United States. Kansas City, which is located in the heart of the nation's winter-wheat belt, has large flour mills.

Other products made in Missouri include fabricated metal products, machinery, and printed materials. Missouri's fabricated metal products include cans, doors, and ammunition. Plants in the St. Louis area make heating and cooling machinery. Printing shops, newspaper and book publishers, and greeting card companies produce most of the printed materials.

Agriculture. Farms cover about two-thirds of Missouri's land area. The state has about 110,000 farms.



Livestock and livestock products account for about 60 percent of Missouri's farm income. Missouri ranks among the leading producers of beef cattle, hogs, and turkeys. Beef cattle and hogs provide most of the income for the state's livestock farmers. Southwest Missouri is the most important area for raising beef cattle. Large numbers of dairy cattle are also raised there. Hog farms are important throughout the state. Farmers in central Missouri raise the most turkeys. Chickens and sheep can also be found on some of the state's farms.

Crops account for about 40 percent of Missouri's farm income. Soybeans are the state's most valuable farm product. Missouri is an important producer of soybeans, corn, and grain sorghum. These crops are used mainly for livestock feed. Soybeans are also used to make oil. Northern Missouri has the largest soybean production. The heaviest concentration of corn farms is in the central part of the state. Eastern Missouri grows the most grain sorghum. Farmers also raise large amounts of cotton, hay, and wheat in Missouri.

Apples, peaches, and grapes are Missouri's most valuable fruits. Truck farms near St. Louis grow a variety of vegetables. Greenhouse and nursery products are im-

Economy of Missouri

This map shows the economic uses of land in Missouri and where the leading farm, mineral, and forest products are produced. Major manufacturing centers are in red.

WORLD BOOK map

portant in the Kansas City and St. Louis areas.

Mining. Lead, limestone, and coal provide most of Missouri's mining income. Missouri leads the states in lead production. Lead is mined in Iron and Reynolds counties in the southeastern part of the state. Copper, silver, and zinc are also produced from the lead mines. Most of the state's limestone comes from quarries near the Mississippi River. Limestone is made into cement and crushed stone for roadbeds. Coal comes mainly from surface mines in Randolph County in the northeastern part of the state. Missouri's other mined products include clays, iron ore, and sand and gravel.

Electric power. Coal-fired steam plants generate about 80 percent of Missouri's electric power. A large hydroelectric power plant at Bagnell Dam in the Ozark Plateau generates electric power mainly for the St. Louis area. A nuclear power plant in Callaway County supplies electric power mainly for eastern and central Missouri.

The Taum Sauk Project near Lesterville is one of the largest pumped-storage hydroelectric plants in the United States. The plant stores and uses the same supply of water over and over again. The water is pumped from a lower reservoir to a higher one. When the water is released from the upper reservoir and flows to the lower one, its flow is used to generate electric power.

Transportation. Missouri's central location, its nearness to raw materials, and the great Mississippi and Missouri waterways have made the state a leading transportation center in the nation.

Lambert-St. Louis International Airport and Kansas City's Mid-Continent International Airport are among the busiest airports in the Midwestern United States. Small airports are scattered throughout the state.

St. Louis and Kansas City are among the largest United States railroad centers. About 20 rail lines provide freight service, and passenger trains serve about 10 cities in the state.

Missouri has about 123,000 miles (198,000 kilometers) of roads and highways. The first land traffic in Missouri followed old Indian trails. In 1860 and 1861, St. Joseph was the eastern terminal of the pony express mail system. Independence marked the eastern starting point of the famous Oregon and Santa Fe trails. Today, Kansas City and St. Louis rank among the nation's leading trucking centers.

Boats and barges can use the Mississippi River for 490 miles (790 kilometers) along the state's eastern border. The Missouri River has about 550 miles (885 kilometers) of commercially navigable waters in the state. St. Louis is one of the busiest inland U.S. ports.

Communication. Two Missouri journalists made newspaper history and influenced journalism across the country. William Rockhill Nelson, founder of *The Kansas City Star,* fought for government reform. Joseph Pulitzer, who founded the *St. Louis Post-Dispatch,* established the Pulitzer Prizes (see **Pulitzer Prizes**).

The first Missouri newspaper, the *Missouri Gazette,* began publication in St. Louis in 1808. Today, Missouri has about 315 newspapers, about 45 of which are dailies. *The Kansas City Star* and the *St. Louis Post-Dispatch* have the largest daily circulations. Missouri publishers also issue about 570 periodicals.

The first radio station in Missouri, WEW of St. Louis University, began broadcasting in 1921. The state's first television station, KSD-TV, started in 1947 in St. Louis. There are now about 180 radio stations and 30 television stations in the state. Cable television systems and Internet providers serve many Missouri communities.

Government

Constitution of Missouri was adopted in 1945. The state had three earlier constitutions, adopted in 1820, 1865, and 1875. An amendment to the Constitution may be proposed by a majority of the members of the state legislature. Or it may be proposed by a petition signed by 8 percent of the voters in two-thirds of the state's congressional districts. To become part of the Constitution, an amendment must be approved by a majority of the voters voting on the amendment. The Constitution requires that the people vote every 20 years, starting in 1962, on whether to call a convention to amend the Constitution.

Executive. The governor of Missouri is elected to a four-year term and is limited to two terms. The governor appoints many of the key officials of state government agencies. The other top state officials are the lieutenant governor, secretary of state, state treasurer, attorney general, and state auditor. These officials are elected to four-year terms.

Legislature of Missouri is known as the General Assembly. It consists of a Senate of 34 members and a House of Representatives of 163 members. Missouri has 34 senatorial districts and 163 representative districts. Voters in each senatorial district elect one senator. Voters in each representative district elect one representative. Senators serve four-year terms and may serve no more than two terms. Representatives serve two-year terms and may serve no more than four terms.

In 1966, a commission *reapportioned* (redivided) the House of Representatives to provide equal representation on the basis of population. Beginning in 1971, both the House and Senate districts have been redrawn every 10 years, based on U.S. census results.

The General Assembly meets every year on the Wednesday after the first Monday in January. The General Assembly's session lasts until the Friday following the second Monday in May. The governor may call special sessions of the Assembly. Special sessions may also be called by petition by three-fourths of the members of the Senate or three-fourths of the members of the House of Representatives.

Courts in Missouri are headed by the state Supreme Court, composed of seven judges. The state Court of Appeals has three districts—the Western district in Kansas City, the Eastern district in St. Louis, and the Southern district in Springfield. The governor appoints the judges of the Supreme Court and the appeals courts for 12-year terms. They are selected from candidates proposed by nonpartisan commissions. Appointed judges must be approved by the voters in the next general election. When their term expires, they must again be approved by the voters to remain in office. Every two

years, the Supreme Court selects one member to serve as chief justice.

The state Constitution also provides for circuit courts, associate circuit courts, and municipal courts. Circuit-court judges serve six-year terms, and the rest serve four years. Judges of circuit and associate circuit courts in Jackson, Platte, Clay, and St. Louis counties—and in the city of St. Louis—are selected like Supreme Court judges. All other Missouri judges are elected.

Local government. Voters in Missouri's 114 counties elect local officials. These officials generally include three commissioners of the county commission, a sheriff, recorder of deeds, prosecuting attorney, collector of revenue, assessor, treasurer, coroner, public administrator, and surveyor. The county commissioners serve as the chief administrators of the county. They are responsible for health, welfare, and public works in the county, and set the county tax rate. The Constitution provides that any county with more than 85,000 residents, or any city with over 10,000 people, may organize its government in the way that best suits its people. Like most Missouri cities, St. Louis has a mayor-council form of government. But St. Louis is an independent city and is not part of any county. It is governed by a mayor, a 28-

*Democratic-Republican. †Liberal Republican. ‡Radical Republican.

member Board of Aldermen, and the board president.

Revenue. Taxes bring in more than half of the state government's *general revenue* (income). Federal government grants and programs account for about a third of the revenue. A general sales tax and a personal income tax each provide more than a third of the tax revenue. Other taxes include those on motor fuels, corporate income, motor vehicle licenses, and insurance. A statewide lottery also contributes to the state's revenue.

Politics. Missouri voters tend to favor Democratic candidates over Republicans, but the balloting is usually close. During the 1900's, Missouri voted for the winner in all except two presidential elections—in 1900 and 1956. For its voting record in presidential elections since 1820, see **Electoral College** (table).

St. Louis and Kansas City vote strongly Democratic, but the region around St. Louis is mostly Republican. Northeastern Missouri, most of the counties along the Missouri River, and southeastern Missouri are traditionally Democratic. North-central and southwestern Missouri are chiefly Republican. About 30 counties switch back and forth between the two major parties. The party that wins these counties generally controls the state legislature.

History

Indian days. Indians known as mound builders lived in the Missouri region long before white people came there. The Indians built large earthwork mounds that still may be seen in various sections of the state (see **Mound builders**). Many tribes of Indians lived in Missouri when Europeans first arrived. The Missouri Indians dwelt in what is now east-central Missouri. The Osage, a tribe of unusually tall Indians, lived and hunted in the areas to the south and the west. Other tribes included the Fox and the Sauk Indians, who lived in the north.

Exploration and settlement. The daring French explorers Father Jacques Marquette and Louis Jolliet were probably the first white people to see the mouth of the Missouri River. In 1673, they marked the spot where the Missouri joins the Mississippi. In 1682, another French explorer, René-Robert Cavelier, Sieur de La Salle, traveled down the Mississippi River and claimed the Mississippi Valley for France. La Salle named the region *Louisiana* in honor of King Louis XIV.

During the years that followed, French trappers and fur traders established trading posts along the river. French missionaries, eager to convert the Indians, founded a number of missions. Indian tales of gold and silver attracted other French prospectors. These adventurers found lead and salt in what is now St. Francois County and remained to mine these minerals. About 1700, Jesuit missionaries established the first white settlement in Missouri, the Mission of St. Francis Xavier. They built it near the present site of St. Louis. The mission was abandoned in 1703 because of unhealthful swamps nearby. About 1735, settlers from what is now Illinois established Missouri's first permanent white settlement, at Ste. Genevieve. In 1764, Pierre Laclède Liguest and René Auguste Chouteau founded St. Louis.

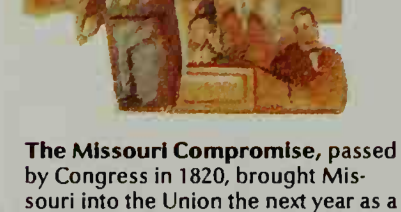
By a secret treaty, signed in 1762, France gave up all its territory west of the Mississippi River to Spain. France and Spain had been allies in the Seven Years' War (see **Seven Years' War**). The Spaniards encouraged pioneers from the East to come to the region, and settlers poured into the Spanish land. One of the pioneers was Daniel Boone, the famous frontiersman. He moved to what is now St. Charles County in 1799, after the Spanish had granted him about 850 acres (340 hectares) of land. In 1800, the Spanish appointed Boone a *syndic,* or judge (see **Boone, Daniel**).

Napoleon Bonaparte, the ruler of France, forced Spain to return the territory west of the Mississippi to France in 1800. By that time, much of present-day Missouri had been explored and many communities had been established. Napoleon, badly in need of money to finance his wars in Europe, sold the Louisiana Territory to the United States in 1803 (see **Louisiana Purchase**). The northern part of the territory was called Upper Louisiana, and included the present state of Missouri. Upper Louisiana extended northward from the 33rd parallel to Canada, and westward to the Rocky Mountains. In 1812, Congress organized the Missouri Territory.

In late 1811 and early 1812, three of the strongest earthquakes ever to hit the United States struck Missouri's New Madrid area. Scientists believe they measured 8 or higher on the Richter scale and were probably more severe than the great San Francisco earthquake of 1906. Fortunately, not many people lived in the region. Property damage and the death toll thus were small compared with the earthquakes' violence.

Territorial days. The Missouri Territory began with a population of more than 20,000. The farming and mining industries were well established, and schools and churches had been built. So many settlers poured into the territory that the Indians became aroused by the loss of their ancient hunting grounds. For several years, the Indians led bloody raids on the frontier settlements.

In 1812, war broke out between the United States and Britain (see **War of 1812**). The British gave weapons to the Indians and encouraged them to attack the Missouri pioneers. The settlers built forts and blockhouses for protection. Even after the war between the United States and Britain ended, the Indians continued to raid many settlements. The attacks ended in 1815, when the Indians and U.S. government officials signed a peace treaty at Portage des Sioux.



Statehood and expansion. In 1818, Missouri asked Congress to be admitted into the Union. The territory had been settled mainly by Southerners who had brought black slaves with them. Missouri's application for admission as a slave state caused a nationwide dispute between slavery and antislavery sympathizers. This dispute was not settled until 1820, when Congress passed the Missouri Compromise. Under this legislation, Missouri entered the Union as a slave state on Aug. 10, 1821. A census in 1820 showed that the territory had 66,586 people, including 10,222 slaves. Missourians elected Alexander McNair as the first governor.

When Missouri entered the Union, it was the western frontier of the nation. The fur trade was the state's most

Historic Missouri

Lewis and Clark started their famous journey to the Pacific Northwest from near St. Louis in 1804. They gave the United States a strong claim to the great Oregon region.

The Missouri Compromise, passed by Congress in 1820, brought Missouri into the Union the next year as a slave state.

Mark Twain, a great American author, was born in 1835 in Florida, Mo. He grew up in Hannibal.

Jesse James, one of the nation's most celebrated bandits, terrorized Missouri for about 16 years following the Civil War. He was born near Centerville (now Kearney).

The Dred Scott Decision was made by the U.S. Supreme Court in 1857. It prevented Missouri slave Dred Scott from gaining freedom, and added to the North-South conflict.

The pony express linked St. Joseph with Sacramento, Calif., in 1860 and 1861. Riders carrying mail on this route covered almost 2,000 miles (3,200 kilometers) in about 10 days.

Important dates in Missouri

1673 Father Jacques Marquette and Louis Jolliet probably became the first white people to see the mouth of the Missouri River.

1682 René-Robert Cavelier, Sieur de la Salle, claimed the Mississippi Valley, including Missouri, for France. He named the region *Louisiana.*

c. 1735 Settlers established Missouri's first permanent white settlement, at Ste. Genevieve.

1762 France gave the Louisiana region to Spain.

1764 Pierre Laclède Liguest and René Auguste Chouteau established St. Louis.

1800 Spain returned the Louisiana region to France.

1803 France sold the Louisiana region to the U.S.

1812 Congress made Missouri a territory.

1815 Indian attacks on Missouri settlements ended when the Indians and United States government officials signed a peace treaty at Portage des Sioux.

1821 Missouri became the 24th state on August 10.

1837 Missouri gained its six northwestern counties as a result of the Platte Purchase.

1854 Border warfare began between antislavery Kansans and proslavery Missourians.

1861-1865 Missouri became a battleground during the Civil War.

1904 The Louisiana Purchase Exposition was held in St. Louis.

1931 Bagnell Dam on the Osage River was completed, forming the Lake of the Ozarks.

1945 Harry S. Truman of Independence became the 33rd President of the United States.

1965 The last section of the stainless steel Gateway Arch was put in place in St. Louis. The nation's tallest monument, it is 630 feet (192 meters) high.

1986 Missouri began operating a statewide lottery.

important industry. In 1822, John Jacob Astor organized a St. Louis branch of the American Fur Company. Within the next 12 years, Astor ruined or bought out most other fur companies. He had a near monopoly on the fur trade west of the Mississippi River.

In 1836, Congress approved the purchase from the Indians of an area known as the Platte Country. By presidential proclamation, it became part of Missouri in 1837. This region extended the northern part of Missouri's western border to the Missouri River.

Since the 1820's, Missourians had been carrying on a regular trade with Mexicans over the Santa Fe Trail. This famous trail linked Independence, Mo., with Santa Fe in the Southwest. Tremendous wealth from the Southwest poured into Missouri, and Independence became a busy, thriving village. The great Oregon Trail, which thousands of settlers followed to the Pacific Northwest, also began in Independence. See **Santa Fe Trail; Oregon Trail.**

The Civil War. In 1857, the Supreme Court of the United States issued the historic Dred Scott Decision. The court ruled that Scott, a Missouri slave, was merely property and did not have citizenship rights. The ruling greatly increased ill feeling between the North and the South (see **Dred Scott Decision**). Meanwhile, many Missourians who lived near the western border of the state feared that the newly organized Kansas Territory would become a free state. As more and more antislavery families settled in Kansas, scattered warfare broke out between Missourians and Kansans (see **Brown, John; Kansas** ["Bleeding Kansas"]). Kansas became a free state in 1861. Fighting between Kansas and Missourians continued into the Civil War.

Missouri became the center of national interest in 1861. The nation wondered whether Missouri would *secede* (withdraw) from the Union and join the Confederacy. Early in 1861, Governor Claiborne F. Jackson recommended that a state convention be called to determine the will of the people. The convention was held in February and March. Jackson and some members of the convention were strongly pro-South, but the convention voted to remain in the Union. Most Missourians wanted to stay neutral if war should come.

After the Civil War began in April 1861, President Abraham Lincoln called for troops from Missouri. Governor Jackson refused Lincoln's call. Union soldiers and the Missouri state militia, which Jackson commanded as governor, clashed at Boonville on June 17, 1861. This battle was the first real fighting of the Civil War in Missouri. The Union troops, under General Nathaniel Lyon, routed the militiamen and gained control of northern Missouri. Jackson and his militiamen retreated to southwestern Missouri, where they reorganized. They then advanced to Wilson's Creek, near Springfield. There, in August, the militiamen and Confederate troops defeated the Union forces in a bloody battle.

On July 22, the state convention had met again. It voted to remove pro-Confederate state leaders from office. The convention replaced them with pro-Union men. Hamilton R. Gamble became governor. In September 1861, Jackson called for the legislature to meet in Neosho in October. Not enough members attended to hold a legal session. But those present voted to secede from the Union and join the Confederacy.

The Confederate forces controlled a foothold in southwestern Missouri until March 1862, when Union forces defeated them at Pea Ridge, Ark. In 1864, General Sterling Price tried to recapture Missouri for the South in a daring raid. He was defeated at Westport, which is a part of present-day Kansas City. Price's defeat marked the end of full-scale fighting in the state. Throughout the war, however, bands of both Union and Confederate guerrillas terrorized the Missouri countryside. These guerrillas burned and looted towns and murdered innocent people.

After the war ended in 1865, Missouri adopted a new constitution. It included a clause that denied the right to vote to anyone who refused to swear that he had not sympathized with the South. This unpopular clause was repealed in 1870.

Progress as a state. Between 1850 and 1870, big changes took place in Missouri. St. Louis and Kansas City became important transportation centers. The frontier disappeared. Trade with Mexico over the Santa Fe Trail ended. The fur trade grew less important, although St. Louis remained one of the world's great fur markets. Tenant farmers replaced the relatively few slaves who worked the fields.

In 1875, Missouri adopted a new constitution. It reestablished the governor's term from two to four years. It also established a state railroad commission to regulate rates and shipping conditions.

For almost 20 years after the Civil War, many former Confederate guerrillas turned to crime. They held up banks, stagecoaches, and trains. In 1881, Governor Thomas T. Crittenden began a campaign to stop the outlaws. He offered a $5,000 reward for the arrest of Jesse James, one of the most notorious bandits. James was killed by one of his own gang in 1882.

The Louisiana Purchase Exposition was held in St. Louis in 1904. This world's fair attracted almost 20 million visitors from the United States and other countries. A popular exhibit featured automobiles. One of the automobiles had been driven all the way from New York City to St. Louis under its own power.

In 1905, Governor Joseph W. Folk began one of the state's most progressive administrations. Missouri adopted statewide primary elections and began political, social, and industrial reforms. Laws were passed calling for the inspection of working conditions in Missouri's factories. Other laws regulated child labor and public utilities in the state.

After the United States entered World War I in 1917, Missouri's mining, manufacturing, and agriculture expanded to supply the nation's armed forces. General John J. Pershing, who was born in Linn County, became commander in chief of the United States forces in France. General Enoch H. Crowder, born in Grundy County, became the first director of the Selective Service System.

Bagnell Dam, an important source of electric power for the St. Louis area, was completed in 1931. The waters held back by the dam formed Missouri's Lake of the Ozarks. Many Missourians lost their jobs during the Great Depression of the 1930's, and farmers suffered because of low prices. Under Governor Guy B. Park, the number of state government employees was cut and operating costs of government were reduced. The federal

State Historical Society of Missouri

The Louisiana Purchase Exposition, also known as the St. Louis World's Fair, was held in the city in 1904. Visitors there saw early types of automobiles and tasted the first ice cream cones.

government set up several agencies in Missouri to provide employment and relief.

The mid-1900's. During World War II (1939-1945), many new industries were developed in Missouri to provide supplies for the armed forces. In 1944, U.S. Senator Harry S. Truman of Independence was elected vice president. He became president after President Franklin D. Roosevelt died in 1945. Truman was elected to a full term as president in 1948.

New industrial plants boosted Missouri's economy during the 1950's. An electronics plant opened in Joplin, and factories in St. Louis and Neosho began producing parts for spacecraft. A uranium-processing plant went into operation in Weldon Spring.

During the 1960's, Missouri conducted a strong drive to attract more industries. It also encouraged tourism, which became a $500-million business annually. The mining industry in Missouri expanded during the 1960's with the discovery of iron ore deposits in Crawford, Dent, Franklin, Iron, and Washington counties.

By the early 1960's, most public schools in Missouri were desegregated. The state Constitution had provided for segregated schools. But in 1954, the Supreme Court of the United States ruled that compulsory segregation of public schools was unconstitutional.

Recent developments. Urban problems became increasingly serious in Missouri during the 1970's. In St. Louis and Kansas City, for example, many middle-class families moved to the suburbs. The population shift drained the cities of much financial support. Inadequate transportation and increasing crime added to problems of Missouri's cities. The big cities are attempting to redevelop their downtown areas to attract new businesses and tourists.

Missouri's farming community suffered during a national farm crisis in the mid-1980's. Many farmers could not afford to keep their farms. A number of Missouri's industries also suffered during this period as foreign trade restrictions were loosened. The state's economy improved in the 1990's.

Missouri also faced environmental problems. Runoff from new land developments muddied lakes and robbed the land of topsoil. Toxic substances, such as pesticides, were found in fish. Contamination from landfills and septic tanks threatened ground water supplies. In the early 1980's, high levels of dioxin, a poisonous substance, were discovered in Times Beach near St. Louis, and in other Missouri areas. The U.S. government bought all the homes and businesses in Times Beach. A cleanup program was begun in 1991. The cleanup was expected to be completed in 1997.

Missouri, like other states, has faced the need for increased revenue for such programs as education, welfare, environmental protection, and bridge and highway construction. In 1986, Missouri began a state lottery to increase its revenue.

Missouri sometimes suffers from flooding along the Mississippi-Missouri river systems. Major floods struck in 1993 as a result of heavy rains. They damaged billions of dollars worth of property and crops in Missouri.

In spite of problems, the state's economy remains strong. Many farm products continue to thrive, and new or expanded factories have sprung up in the cities. In addition, tourism has become a billion-dollar industry for Missouri. St. Louis, Kansas City, and Springfield attract major business, religious, and political conventions. The Ozarks draw vacationers from a wide area. The Ozark town of Branson became a major center for the country music industry by the early 1990's.

Missouri, University of, is a coeducational state university system. It has four campuses.

The University of Missouri-Columbia campus grants degrees in agriculture, arts and science, business and public administration, education, engineering, fine arts, forestry-fisheries-wildlife, human environmental sciences, journalism, law, library and information science, medicine, nursing, social work, and veterinary medicine. Its school of journalism, founded in 1908, is the oldest in the world.

The University of Missouri-Kansas City campus grants degrees in arts and sciences, basic life sciences, business and public administration, computer science and telecommunications, dentistry, education, law, medicine, music, nursing, and pharmacy. The school was founded as the privately controlled University of Kansas City in 1929. It became part of the University of Missouri in 1963.

The University of Missouri-Rolla campus offers degrees in arts and sciences, engineering, and mines and metallurgy. It was founded in 1870.

The University of Missouri-St. Louis campus grants degrees in arts and sciences, business administration, education, nursing, and optometry. The school was founded as an urban campus of the University of Missouri in 1963.

Each campus also provides a graduate program. The University of Missouri was founded in 1839 in Columbia. It is the oldest state university west of the Mississippi River. Critically reviewed by the University of Missouri

Missouri Compromise was a plan agreed upon by the United States Congress in 1820 to settle the debate over slavery in the Louisiana Purchase area. The plan temporarily maintained the balance between free and slave states.

In 1818, the Territory of Missouri, which was part of the Louisiana Purchase, applied for admission to the Union. Slavery was legal in the Territory of Missouri, and about 10,000 slaves lived there. Most people expected Missouri to become a slave state. When the bill to admit Missouri to the Union was introduced, there were an equal number of free and slave states. Six of the original 13 states and five new states permitted slavery, while seven of the original states and four new states did not. This meant that the free states and the slave states each had 22 senators in the United States Senate. The admission of Missouri threatened to destroy this delicate balance.

This balance had been temporarily upset a number of times, but it had always been easy to decide whether

states east of the Mississippi River should be slave or free. Mason and Dixon's Line and the Ohio River formed a natural and well-understood boundary between the two sections. No such line had been drawn west of the Mississippi River. In addition, some parts of Missouri Territory lay to the north of the mouth of the Ohio River, while other parts of it lay to the south.

A heated debate broke out in Congress when Representative James Tallmadge of New York introduced an amendment to the bill enabling Missouri to become a state. Tallmadge proposed to prohibit the bringing of any more slaves into Missouri, and to grant freedom to the children of slaves born within the state after its admission. This proposal disturbed Southerners, who found cotton growing by means of slave labor increasingly profitable, and feared national legislation against slavery. Because the free states dominated the House of Representatives, the slave states felt they must keep the even balance in the Senate.

The Tallmadge Amendment passed the House, but the Senate defeated it. During the next session of Congress, Maine applied for admission to the Union. Missouri and Maine could then be accepted without upsetting the Senate's balance between free and slave states, and the Missouri Compromise became possible.

The compromise admitted Maine as a free state and authorized Missouri to form a state constitution. A territory had to have an established constitution before it could become a state. The compromise also banned slavery from the Louisiana Purchase north of the southern boundary of Missouri, the line of 36° 30′ north latitude, except in the state of Missouri.

The people of Missouri believed they had the right to decide about slavery in their state. They wrote a constitution that allowed slavery and that restricted free blacks from entering the state.

Before Congress would admit Missouri, a second Missouri Compromise was necessary. Henry Clay, the Speaker of the House, helped work out this agreement. It required the Missouri legislature not to deny black citizens their constitutional rights. With this understanding, Missouri was admitted to the Union in 1821.

In 1848, Congress passed the Oregon Territory bill, which prohibited slavery in the area. President James K. Polk signed the bill because the Oregon Territory lay north of the Missouri Compromise line. Later proposals tried to extend the line by law across the continent to the Pacific Ocean. These efforts failed. The Missouri Compromise was repealed by the Kansas-Nebraska Act of 1854 (see **Kansas-Nebraska Act**). William E. Foley

Missouri River is the longest river in the United States. It flows 2,565 miles (4,130 kilometers) from its source, the Jefferson River at Red Rock Creek in southwestern Montana, to its mouth on the Mississippi River. The Missouri drains an area of about 529,000 square miles (1,371,100 square kilometers). This drainage basin includes all or parts of 10 U.S. states and 2 Canadian provinces.

The Missouri has much mud in its water. Early explorers and Indians called it the *Big Muddy,* and farmers have described it as "too thick to drink and too thin to plow." The source of the river's name is unclear. The river may have been named after an Indian village called *OueMessourit* or *Ou-Missouri* located near its mouth. The village name means *town of the large canoes.*

The course of the Missouri. The headwaters of the Missouri are at Red Rock Creek in southwestern Montana, where the Jefferson River, a small rushing stream high in the Rocky Mountains, begins. At Three Forks, Montana, the Jefferson joins the Madison and Gallatin rivers to form the Missouri.

The Missouri flows north from Three Forks and cuts through a spectacular gorge called the Gates of the Mountains. Then it bends toward the northeast and plunges down a series of waterfalls known as the Great Falls of the Missouri. The city of Great Falls, Montana, at the foot of the waterfalls, is named for these waterfalls. From Great Falls, the Missouri winds eastward across Montana. In North Dakota, the river makes a great bend southward. Then it flows southeast across South Dakota.

The Missouri forms part of the boundary between South Dakota and Nebraska. It turns south at Sioux City, Iowa, and flows between Iowa and Nebraska. The river also forms the Nebraska-Missouri boundary and part of the Missouri-Kansas boundary. At Kansas City, Missouri, the river turns east again. It flows across Missouri and joins the Mississippi River about 20 miles (32 kilometers) north of downtown St. Louis. Every second, the Missouri empties an average of 76,300 cubic feet (2,161 cubic meters) of water into the Mississippi.

The Missouri, like most rivers, has an upper, middle, and lower part. The upper Missouri is a clear, rapid-flowing stream in western Montana's mountains. The middle Missouri begins just below Great Falls, where the river leaves the mountains and moves onto the Great Plains. The middle Missouri is slower and muddier than the upper part. The lower Missouri is the slowest and muddiest part. It begins just downstream from Yankton, South Dakota, and extends to the Mississippi.

The Platte River is the longest branch of the Missouri. Other major tributaries include the James, Kansas, Milk, Osage, and Yellowstone rivers.

Navigation. The Missouri River was once used for commercial navigation along most of its course. Today, almost all traffic upstream from Sioux City is recreational, but commercial activity thrives on the lower Missouri. The commercial river traffic is extremely important to farmers of the western part of the Midwest. It carries their goods to market and brings them fertilizer and other farm supplies. The chief ports on the river are Kansas City, Missouri; Omaha, Nebraska; and Sioux City.

Commercial traffic on the Missouri totals more than $3\frac{1}{4}$ million tons (3.2 million metric tons) of freight each year. Freight headed downstream consists mainly of such farm products as corn, sorghum, soybeans, and wheat. Upstream cargoes include benzine, cement, fertilizer, lime, paint, and phosphate. Most of the freight travels on barges pushed by powerful tugboats. A navi-

gation channel at least 300 feet (91 meters) wide and 9 feet (2.7 meters) deep is maintained on the river between Sioux City and the Mississippi.

Dams and reservoirs. A series of six huge dams form a nearly continual chain of long, winding reservoirs along the middle Missouri River. These dams, in order from north to south along the river, are Fort Peck, Garrison, Oahe, Big Bend, Fort Randall, and Gavins Point. About 60 smaller dams and reservoirs are on tributaries of the Missouri. See **Fort Peck Dam; Fort Randall Dam; Garrison Dam.**

Flooding was once a serious problem on the Missouri. In spring, excess water from melting snow often caused the river to overflow, causing widespread damage. The six large dams on the middle Missouri have nearly eliminated this problem. The reservoirs of the dams store excess water in spring and gradually release it during the rest of the year, thus greatly reducing floods downstream.

The dams and their reservoirs also provide other services. Hydroelectric powerhouses at the dams generate electricity used by farms, homes, and industries throughout the middle Missouri Basin. Millions of visitors use the reservoirs annually for boating, fishing, swimming, and water skiing. Water from the reservoirs is also used to irrigate farmland and serve cities along the river.

Wildlife and conservation. The Missouri and its valley provide a rich habitat for a wide variety of wildlife. Bears, deer, elk, moose, and other large animals live in the mountainous upper Missouri Valley. Smaller animals, such as beavers, foxes, muskrats, rabbits, skunks, and weasels, are common along the middle and lower parts of the river. Fishes of the cool, clear upper Missouri include graylings and rainbow trout. Bass, bullheads, catfish, carp, and perch inhabit the warmer, muddier waters below Great Falls.

The upper Missouri River flows through forests of fir, hemlock, and spruce trees. The middle and lower sections of the river wind through grasslands. Forests of cottonwoods, hickories, oaks, poplars, and willows also lie along the middle and lower sections of the Missouri.

At one time, pollution threatened much of the wildlife along the Missouri. Pesticides and other chemicals used by farmers were washed into the river, and industries dumped wastes into it. These substances poisoned fish and other wildlife. Today, federal laws ban certain pesticides, and industrial discharges into the river are carefully controlled. As a result, the quality of the water is gradually improving.

History. The Missouri River was formed about 20 million years ago, during the late Tertiary Period. During the Pleistocene Ice Age, about 2 million years ago, the river marked the southern and western edge of many of the huge ice sheets that covered the land.

The Missouri River Basin was the home of several Indian tribes. The Wind River Shoshone and Atsina lived near the headwaters of the river, in western Montana. Several buffalo-hunting tribes occupied the Missouri Basin between eastern Montana and the Mississippi.

They included the Arikara, the Assiniboine, the Dakotah (Sioux), the Hidatsa, the Kansa, the Missouri, and the Omaha. Many of these tribes spent much of their time on the grasslands away from the river. But the Missouri was a valuable water source, a favorite hunting ground, and an important route for their canoes.

The first whites to see the Missouri River were the explorers Jacques Marquette of France and Louis Jolliet, a French Canadian. They reached the mouth of the Missouri in 1673 while exploring the Mississippi. The United States bought the Missouri River Basin from France in 1803 as part of the Louisiana Purchase. From 1804 to 1806, two Americans, Meriwether Lewis and William Clark, explored the territory drained by the Missouri. See **Lewis and Clark expedition.**

During the early 1800's, the Missouri became one of the main transportation routes of the fur trade in the West. At first, keelboats hauled furs and supplies on the river. Steamboat traffic began on the Missouri in 1819, and steamers soon became the chief means of transportation. Many pioneers who traveled west in the mid-1800's went at least part of the way on a Missouri steamer. Traffic on the river declined after railroads were built in the West during the late 1800's. But today, the lower Missouri River is an important commercial waterway.

Major floods struck along the river in 1943, 1947, 1951, 1952, and 1993. But the six huge dams on the middle Missouri and the smaller dams on the tributaries have greatly reduced the threat of disastrous flooding. These dams make up the heart of the Pick-Sloan Missouri Basin Program. This program, which was authorized by Congress in 1944, is a flood control, electric power, and irrigation project. Under the program, 39 dams were constructed on the Missouri and its tributaries by the early 2000's. John Edwin Coffman

Mist. See Fog.

Mistletoe is a plant that grows as a parasite on the trunks and branches of various trees. The *American mistletoe* and the *European mistletoe* grow most often on apple trees. They also may grow on other trees, such as the lime, hawthorn, sycamore, poplar, locust, fir, and occasionally on oak. The *dwarf mistletoe* is a small variety that grows on pines in the eastern United States.

Mistletoe is an evergreen with leathery, oblong leaves. It has tiny yellow flowers that bloom in February and March. Birds eat the white, shiny fruits called berries. The berry seeds cling to the bills of birds and are scattered when birds sharpen their bills against the bark of trees. The berries may be poisonous to people.

WORLD BOOK illustration by Robert Hynes

American mistletoe

Mistletoe is associated with many traditions and holidays, especially Christmas. Historians say the Druids—ancient priests of the Celts—cut the mistletoe that grew on the sacred oak and gave it to the people for charms. In Teutonic mythology, an arrow of mistletoe killed Balder, son of the goddess Frigg. Early European peoples used mistletoe as a ceremonial plant. The custom of using mistletoe at Christmastime probably comes from this practice. In many countries, tradition says that a person caught standing beneath mistletoe must forfeit a kiss. James S. Miller

Scientific classification. Mistletoe belongs to the mistletoe family, Loranthaceae. The American mistletoe is *Phoradendron serotinum.* The dwarf mistletoe is *Arceuthobium pusillum.*

Mistral, *mee STRAL,* **Frédéric,** *fray day REEK* (1830-1914), was a famous French poet who won the 1904 Nobel Prize in literature. He wrote in modern Provençal, the language of southern France. Mistral led a movement of the 1800's called the *Felibrige,* which tried to revive the literary tradition and enrich the language of the medieval troubadours (see **Troubadour**).

In 1859, Mistral produced his masterpiece, *Mirèio* (also called *Mireille*), an epic describing the tragic love of a farmer's daughter in the valley of the Rhône River. The poem's success did much to gain sympathy for the Provençal revival in literature. In addition to *Song of the Rhône* (1897) and other poems, Mistral compiled *Lou Tresor dóu Felibrige* (1876-1886), a dictionary of *langue d'oc,* the general term used for the dialects of southern France. He was born on Sept. 8, 1830, near Arles, and died on March 25, 1914. Jean-Pierre Cauvin

Mistral, *mees TRAHL,* **Gabriela,** *gah bree EH lah* (1889-1957), was the pen name of Lucila Godoy Alcayaga, a Chilean poet and educator. In 1945, she became the first Latin American writer to win the Nobel Prize for literature. Her spare, plain style with its often Biblical flavor gave Spanish American poetry a fresh direction. She was a student of folk verse, particularly children's rhymes and lullabies, and drew on these forms in developing her poetry. Her best-known books of poetry include *Desolation* (1922), *Tenderness* (1924), *Felling of Trees* (1934), and *Wine Press* (1954).

Mistral was born on April 7, 1889, in Vicuña, Chile. She was a rural schoolteacher and later became a prominent educator in Chile. She served in the foreign service of Chile and at the League of Nations. Mistral taught in the United States in the 1930's. She died on Jan. 10, 1957. Naomi Lindstrom

Mitanni, *mih TAN ee,* was an ancient kingdom in northern Mesopotamia. The kingdom was in what is now southeastern Turkey. The Mitannians used horses and were skilled in the use of chariots in war. The neighboring Hittites learned how to use chariots in warfare from the Mitannians. In the 1400's B.C., the Mitannians fought the Egyptians for control of Syria. But both kingdoms feared the rise of Hittite power. A Mitannian princess married into the Egyptian royal family as a sign of unity. About 1370 B.C., however, the Hittites defeated the Mitannians. Civil war further weakened them, and the kingdom was finally absorbed into the Assyrian Empire by about 1350 B.C. Thomas W. Africa

Mitchel, John Purroy (1879-1918), was elected reform mayor of New York City in 1913. His election ended, for a time, control by Tammany Hall, a notorious political group.

Mitchel reduced the city debt, fought dishonesty in the New York City police department, and set up a relief fund and workshops for the unemployed. However, a number of Mitchel's actions angered the city's powerful

interests, and he lost his bid for reelection in 1917.

Mitchel was born in Fordham, New York, and graduated from New York Law School. In 1906, as a commissioner of accounts for the city, he exposed dishonest practices of two borough presidents, the fire department, and the licenses bureau.

Charles B. Forcey and Linda R. Forcey

Mitchell, Arthur (1934-), was the first black American to dance with a major classical ballet company. He performed with the New York City Ballet from 1955 to 1970.

Mitchell was born in New York City and attended the School of American Ballet. In 1955, he joined the New York City Ballet. His major roles included the part of Puck in *A Midsummer Night's Dream* and the *pas de deux* (dance for two persons) in *Agon*.

In 1969, Mitchell formed the Dance Theatre of Harlem, a professional ballet company in New York City's chief black community. The company is best known for its varied repertoire, including a version of the 1841 romantic ballet *Giselle* now set in the Louisiana bayou. Mitchell directs the company, teaches in the school, and composes dances. As a *choreographer* (creator of dances), Mitchell created such works as *Holberg Suite* (1970), *Rhythmetron* (1971), *Manifestations* (1975), and *John Henry* (1988). Katy Matheson

Mitchell, Billy (1879-1936), a United States Army general, was one of the most controversial figures in American military history. An early and vigorous advocate of airpower, he was court-martialed for defiance of his superiors in 1925. He resigned from the Army rather than accept a five-year suspension. He was branded at first as an extremist and insurgent. But early in World War II (1939-1945), events confirmed many of his predictions. In 1946, Congress authorized the Medal of Honor for him.

Mitchell enlisted in the Army as a private at the start of the Spanish-American War in 1898. He remained in the Army and rose rapidly in the Signal Corps, which first controlled the development of aviation in the U.S. Army. Mitchell learned to fly in 1916, and became air adviser to General John Pershing in World War I (1914-1918). He was in Europe when the United States entered the war, and quickly got in touch with Allied air leaders. Mitchell commanded several large air units in combat, including the largest concentration of Allied airpower of the war, during the Battle of St.-Mihiel. Mitchell had become a brigadier general by the time the war ended.

After the war, Mitchell became assistant chief of the Air Service, and the leading advocate of an air force independent of the Army and the Navy. He found a natural resistance among leaders of the older services, and appealed to the public through books, magazine articles, newspaper interviews, and speeches. Because airplanes were then limited in size and range, many people thought his claims for airpower were exaggerated. But he persuaded many others, especially after a 1921 experiment when he sank three former German ships—a destroyer, a cruiser, and a battleship—with aerial bombs. He repeated this success in tests against three obsolete U.S. battleships. However, Mitchell failed to achieve his goal, perhaps partly because he was often violent in argument and bitter in his condemnation of the military superiors who disagreed with his ideas.

William Mitchell was born in Nice, France, of American parents. He wrote *Our Air Force* (1921), *Winged Defense* (1925), and *Skyways* (1930). Alfred Goldberg

Mitchell, George John (1933-), was a United States senator from Maine from 1980 to 1995. Mitchell, a Democrat, was Senate majority leader from 1989 until he retired in 1995. He had been appointed to the Senate in 1980 to finish the unexpired term of Edmund S. Muskie. Muskie resigned his seat to become secretary of state under President Jimmy Carter. Mitchell won election to a full term in 1982 and was reelected in 1988.

Mitchell was born in Waterville, Maine. He graduated from Bowdoin College in 1954. In 1960, he earned a law degree from Georgetown University. From 1960 to 1962, Mitchell worked as a trial lawyer at the U.S. Department of Justice. He served as an assistant to Senator Muskie from 1962 to 1965. From 1966 to 1968, he was chairman of the Democratic Party in Maine. He was elected to the Democratic National Committee in 1969 and served on the committee until 1977. From 1977 to 1979, he was U.S. attorney for the state of Maine. From 1979 to 1980, he served as U.S. district judge for that state.

In 1995, after Mitchell left the Senate, he became President Bill Clinton's special envoy for Northern Ireland. He chaired negotiations to end the conflict (see Northern Ireland [Recent developments]). Lee Thornton

Mitchell, Joan (1926-1992), an American painter, was a major figure in the artistic movement known as abstract expressionism. Abstract expressionists tried to capture the artist's emotions and the way in which the art was physically made. Like many abstract expressionist works, Mitchell's works seem spontaneous. But they were carefully constructed. She built up pigment layers to create a network of colors that suggest her intended subject.

Mitchell was born in Chicago. Her early experience of the landscape around Lake Michigan became the basis for much of her art. Black, blue, and white often appear in her paintings, and many of her paintings refer to childhood memories of cold and snow. During the early 1950's, Mitchell was influenced by such abstract expressionist artists as Willem de Kooning and Franz Kline. She soon adopted their manner of intense and emotional painting. Mitchell settled in France in 1959.

Rebecca Jeffrey Easby

See also Abstract expressionism.

Mitchell, John Newton (1913-1988), served as attorney general of the United States from 1969 to 1972. He was one of President Richard M. Nixon's most influential advisers on both domestic and international problems. Mitchell was a central figure in the Watergate political scandal, and in 1975 he became the only attorney general ever convicted of a felony (see Watergate).

Mitchell resigned as attorney general in March 1972 to become director of the Committee for the Re-election of the President (CRP), a post he held for only four months. Two other CRP officials were among the seven men involved in the June 1972 burglary of Democratic Party headquarters at the Watergate complex in Washington, D.C. In 1977, after he had been convicted of con-

spiracy, obstruction of justice, and perjury, Mitchell began serving a 2 $\frac{1}{2}$ - to 8-year prison term. His sentence was reduced to 1 to 4 years, and he was paroled in 1979.

Mitchell was born in Detroit. He grew up in New York City and graduated from Fordham University and Fordham Law School. As a lawyer, Mitchell handled state and municipal bond issues and was considered an expert in public finance. Mitchell's New York City law firm merged with Nixon's in 1967. Mitchell served as Nixon's presidential campaign manager in 1968.

Stephen E. Ambrose

Mitchell, Margaret (1900-1949), an American author, wrote *Gone with the Wind* (1936), one of the most popular novels of all time. It won the 1937 Pulitzer Prize for fiction.

Gone with the Wind is a story of the South during the Civil War, written from the Southern point of view. The story begins just before the outbreak of the war in 1861. It describes the impact of the conflict on the South and ends during the postwar Reconstruction period. The two main characters—the Southern belle Scarlett O'Hara and the dashing Rhett Butler—rank among the best-known figures in American fiction. The motion picture *Gone with the Wind* (1939) became one of the most popular films ever made.

Mitchell was born in Atlanta, Georgia, where much of the action of *Gone with the Wind* takes place. She wrote the novel over a period of 10 years. *Margaret Mitchell's "Gone with the Wind" Letters: 1936-1949* was published in 1976. Alexandra Ripley wrote a continuation of the Mitchell novel that was published in 1991 as *Scarlett: The Sequel to Margaret Mitchell's Gone with the Wind.*

Noel Polk

Mitchell, Maria (1818-1889), an American astronomer, became known for her studies of sunspots and of satellites of planets. Mitchell discovered a new comet in 1847. Although she was largely self-educated, she served as professor of astronomy at Vassar College from 1865 to 1888. Mitchell was elected into several learned societies. In 1848, she became the first woman member of the American Academy of Arts and Sciences. She later became a fellow of the society. She was elected to the Hall of Fame for Great Americans in 1905. Mitchell was born in Nantucket, Massachusetts.

C. R. O'Dell

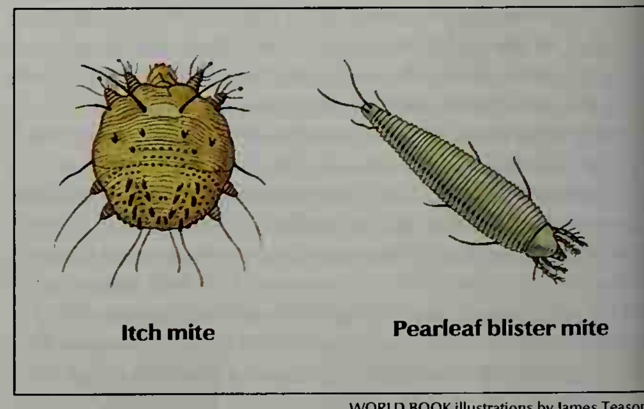
Mitchell, Wesley Clair (1874-1948), was an American economist known for his studies of the rise and fall in business activity. Mitchell collected data about prices, production, and other factors in periods of prosperity and during economic slumps. He then determined the probable causes of the recurring increase and decrease in economic activity called the *business cycle.*

Mitchell pioneered the use of detailed statistics in economic studies. During his time, most economists developed theories based on only a few observations. Mitchell believed economic theories should be supported by a large amount of statistical evidence. Most economists today use the combined theoretical and statistical approach begun by Mitchell.

In 1920, Mitchell helped found the National Bureau of Economic Research. This private nonprofit organization conducts research on a variety of economic problems. Mitchell served as the organization's director from 1920 to 1945. See **National Bureau of Economic Research.**

Mitchell was born in Rushville, Illinois. He taught economics at Columbia University from 1913 to 1919 and from 1922 until 1944. His books include *Business Cycles* (1913) and *Business Cycles: The Problem and Its Setting* (1927). Barry W. Poulson

Mite is the common name for a type of small animal related to ticks. Mites and ticks are not insects. They are related to spiders and scorpions.



Some mites live on land, while others live in water. Some are too small to be seen easily with the naked eye and must be studied under a microscope. The adult usually has a saclike body with a slight dividing line between its abdomen and thorax, and has four pairs of legs. The mouth has piercing and grasping organs. The digestive system begins in the sucking beak. The young larvae of most species hatch from eggs and have six legs. They shed their skins and change into nymphs with eight legs. After one or more other moltings, the nymphs change into adults.

Many kinds of mites live at least part of their lives as parasites. They suck the blood of animals or the juice from plants, and eat cell tissues as well. Other mites eat feathers, cheese, flour, cereal, drugs, and other stored products. Several kinds of mites burrow into the skin of people and other mammals, especially horses, cattle, and sheep. They cause the skin to break out and itch, forming scabs and mange. The troublesome *chiggers,* or *red bugs,* which torment people in the woods, are larvae of mites. Another kind that attacks people is a long wormlike mite that burrows into the hair follicles and the oil glands. All these mites except the last can be repelled by sulfur preparations.

Several kinds of mites attack poultry. The best-known of these species is the common *chicken mite,* which sucks the blood of its victims at night and hides in cracks during the day.

Sometimes a mite called the *red spider* destroys greenhouse plants. The *pearleaf blister mite* damages fruit trees. *Gall mites* form small lumps on leaves and twigs. Unlike other mites, they have only two pairs of legs. *Clover mites* attack plants and fruit trees. In late autumn, large numbers of these mites often move indoors to avoid the cold weather. Other mites attack bulbs and roots of plants. A few species prey on plant lice, or aphids, and others on insects and grasshopper eggs. Many species live in the soil and help break down dead plant and animal tissues. Edwin W. Minch

Scientific classification. Mites belong to the order Acarina. The scientific name for the itch mite of human beings is *Sar-*

WORLD BOOK illustrations by James Teason

coptes scabiei. The skin mite of horses and cattle is *Psoroptes ovis.* The chicken mite is *Dermanyssus gallinae.* The red spider is *Tetranychus bimaculatus,* or some closely related species.

Mithra, *MIHTH ruh,* was a god of the tribes of the Aryans who settled in ancient Persia. Mithra, also known as Mithras, is the same god as Mitra, the sun god who appears in the ancient literature of Hinduism called the Vedas.

According to Zoroastrian religious tradition, Mithra was the god of light, closely associated with the sun. Mithra was said to be an ally of the supreme god Ahura Mazda. Under Ahura Mazda's leadership, Mithra and other gods fought against Angra Mainyu, the Zoroastrian god of evil (see **Zoroastrianism**).

The Persians spread the worship of Mithra, called Mithraism, throughout Asia Minor. The cult became popular, especially among Roman soldiers and slaves. By about A.D. 100, they had spread it into Europe. Mithraism ranked as a principal competing religion of Christianity until the 300's. Robert William Smith

Mithridates VI, *MITH rih DAY teez* (120?-63 B.C.), was king of Pontus, an area in what is now Turkey. One of Rome's most dangerous enemies, Mithridates opposed Roman expansion into Asia Minor.

Mithridates fought three wars against Rome. The first of these wars occurred in 90 B.C., when Rome's Italian allies in central and southern Italy revolted. Mithridates drove the Romans from Asia. He ordered every Roman citizen in Asia Minor killed. An estimated 80,000 people were put to death.

When Rome attacked Mithridates's allies in Greece, he sent two armies there. But Sulla, a Roman general, defeated them, and Mithridates had to make peace in 84 B.C. The greatest war broke out in 75 B.C. when Rome took over Bithynia, a region adjoining Pontus. The Roman general Pompey drove Mithridates out of Asia Minor. Mithridates planned to continue the war from the Crimea in what is now southern Ukraine. But his son, Pharnaces, rebelled against him. Mithridates had himself killed by a bodyguard. Clive Foss

Mitochondria, *MY tuh KAHN dree uh,* are the parts of a cell that convert chemical energy from food into a form of energy the cell can use. Mitochondria use energy released by the breakdown of carbohydrates and fats to make a compound called *adenosine triphosphate* (ATP). Cells use ATP to power movement, transport substances into or out of the cell, and create chemicals needed to grow and divide. In many cells, mitochondria appear as spheres or short rods outside the nucleus, while in others they may form a network of small tubes.

Mitochondria are essential for the proper growth and function of nearly all cells. Defects in mitochondria can cause some forms of blindness, deafness, mental retardation, and neuromuscular disease. Some scientists believe that decreased activity of mitochondria in the cells over time is responsible for some diseases associated with aging, such as Parkinson's and Alzheimer's disease.

Mitochondria contain their own DNA (deoxyribonucleic acid) separate from the DNA in the cell's nucleus. Unlike the DNA of the nucleus, which contains hereditary material from both parents, mitochondrial DNA in animals and human beings is inherited only from the mother. This separate DNA is useful to biologists, who can analyze it to help determine evolutionary relationships between organisms. Michael P. Yaffe

See also **Cell** (The cytoplasm; Producing energy).

Mitosis. See **Cell** (Cell division; illustration).

Mitral valve prolapse, sometimes called MVP, is a common heart valve disorder. The mitral valve is between the left atrium and the left ventricle of the heart. It has two *leaflets* (flaps) that control the blood flow. MVP occurs when one or both of the leaflets are enlarged or have extra tissue. MVP is usually harmless. However, major complications can occur, including a blood clot in the brain and an infection called *infective endocarditis* involving the mitral valve as well as other valves. MVP appears twice as often in women as in men. It is most commonly a hereditary disorder.

Some people with MVP have no symptoms. However, most patients experience a rapid or irregular heartbeat, shortness of breath, light-headedness, and chronic fatigue. Many patients also suffer from migraines, eating and sleeping disorders, an overactive or inflamed thyroid gland, diarrhea, and cold hands and feet. Emotional stress often magnifies the symptoms.

Doctors generally prescribe regular exams and aerobic exercise for people who have MVP. Patients also are advised to restrict their intake or use of high-carbohydrate foods, caffeine, and decongestants. Some patients may need beta-blockers and specific antiarrhythmic medication. More severe cases may require surgery to repair or replace the valve or to insert an electronic regulator, such as a pacemaker or defibrillator.

Carl E. Eybel

See also **Heart** (Chambers, valves, and inner lining; illustration: Parts of the heart; Valve disease).

Mitropoulos, *mih TRAHP uh luhs,* **Dimitri** (1896-1960), was a symphony orchestra and opera conductor. He conducted a wide repertory and was particularly successful with works of the 1900's. He won praise for the passion and sweep of his interpretations.

Mitropoulos was born in Athens, Greece. He received the most important part of his music education in Berlin as a student of Ferruccio Busoni, an Italian composer and pianist. After building a European reputation, Mitropoulos made his United States debut in 1936 with the Boston Symphony Orchestra. From 1937 to 1949, he was chief conductor of the Minneapolis Symphony Orchestra. He was the principal conductor of the New York Philharmonic Orchestra from 1949 to 1958. From 1954 until his death, Mitropoulos was also a conductor at the Metropolitan Opera, where he specialized in the operas of Giuseppe Verdi and Richard Strauss.

Martin Bernheimer

Mitterrand, *MEE tehr ahn,* **François Maurice** (1916-1996), served as president of France from 1981 to 1995. A member of the Socialist Party, Mitterand was France's first leftist president since 1958. He retired in 1995 at the end of his second term. Jacques Chirac, a conservative, succeeded him.

After Mitterrand took office, the government bought controlling interests in some important businesses in France. But Mitterrand later moved away from government control of enterprises and from increased government spending on social programs. He focused on reducing inflation and encouraging private investment. During the last years of Mitterrand's presidency, how-

ever, unemployment in France rose to a high of 12 percent.

Mitterrand worked to strengthen France's ties with other European nations and with the United States. He built a strong relationship with Germany and increased France's role in the European Union (EU). He was one of the creators of the EU's plan to establish a common currency and a central bank for its member nations.

Mitterrand was born in Jarnac, near Cognac. In 1938, he earned a diploma in law from the University of Paris and in political science from the École des Sciences Politiques. In 1940, while serving in the army during World War II, he was wounded and imprisoned by the Germans. He escaped in 1941. For a short time, he worked for the German-controlled government of occupied France. By 1943, he was working secretly for the French resistance movement.

From 1946 to 1958, Mitterrand was a member of the National Assembly in the French Parliament, and he held a number of cabinet posts. From 1958 to 1962, he served in the Parliament's Senate. In 1962, he again became a member of the National Assembly and continued to serve until elected president.

When Mitterrand was a student in the 1930's, most of his associates were right-wing conservatives. Mitterrand's political views shifted as he grew older. He became a moderate, and then he moved toward left-wing socialism. John F. Sweets

Miwok Indians, *MEE wahk,* is the name of three groups in northern California who speak related languages. The three are (1) the Lake Miwok, who traditionally lived south of Clear Lake; (2) the Coast Miwok, who made their homes near the Pacific coast just north of present-day San Francisco; and (3) the Eastern Miwok, who lived in central California, south of what is now Sacramento (see **California** [physical map]).

Traditionally, each of the three Miwok groups consisted of smaller units called *tribelets.* A typical tribelet was made up of several villages. Each Lake or Eastern Miwok tribelet had its own hereditary chief. Each Coast Miwok tribelet chose two chiefs—one male and one female—and a female ceremonial leader, or *maien.*

The Miwok lived in houses made of bark, grass, and other materials. Some homes stood partly underground and were covered with branches and earth. For food, the Miwok fished and hunted and gathered acorns and other wild plant foods.

In the early 1800's, Spaniards captured many Miwok to work as laborers on missions and ranches. In the 1820's and 1830's, some Miwok fought for their territory. The United States Army killed many Miwok in a series of massacres in the 1850's. Many Miwok live in California. Some dwell on *rancherias,* small tracts of land reserved for Indian use. According to the U.S. census, there are about 3,400 Miwok. Victoria D. Patterson

Mix, Tom (1880-1940), became one of America's most famous motion-picture cowboys. He entered the movies in 1910. His expert horsemanship and easygoing manner made him a star. He appeared in such Western movies as *Riders of the Purple Sage* (1925). Mix and his horse, Tony, were given a reception by the Lord Mayor of London in 1925.

Mix was born in Mix Run, Pennsylvania, near Du Bois. He joined the United States Army to fight in the Spanish-American War (1898). But he was not involved in combat duty. Louis Giannetti

Mixtec Indians, *MEESH tehk,* maintained one of the most important cultures in central Mexico from about A.D. 900 until about 1520. Beginning in about A.D. 900, they established kingdoms in mountainous parts of what are now the Mexican states of Guerrero, Oaxaca, and Puebla. The Mixtec kingdoms competed with one another for political power in the region. Beginning in the 1200's, Mixtec kingdoms integrated with kingdoms of the Zapotec Indians through intermarriage of rulers and political alliances. The Mixtec also conquered several smaller Zapotec kingdoms in the Valley of Oaxaca. Later, the Mixtecs came under the rule of the Aztec Empire.

The Mixtec produced many sophisticated works of art, including ceramics, jewelry, and small carvings. They used such materials as bone, clay, gold, jade, silver, turquoise, and wood. Among the most important surviving works of Mixtec art are several *codices* (historical manuscripts). These books used *pictographs* (a system of writing with pictures) to record information about ruling families and their conquests (see **Indian, American** [picture: The arts of Middle America]). The Mixtec style of art had widespread influence on other Middle American cultures, including that of the Aztec.

About 170,000 people who speak Mixtec dialects still live in the states of Oaxaca and Puebla. Most are farmers and herders. William O. Autry

Moa, *MOH uh,* is any one of about 13 *species* (kinds) of extinct birds that once lived on the North Island and the South Island of New Zealand. Moas ranged in size from those as big as a large turkey to some that were 10 to 13 feet (3 to 4 meters) tall. Moas could not fly. They had small heads, long necks, stout legs, and no wings. They ate fruits and leaves.

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd

The moa is an extinct bird that looked somewhat like an ostrich. Some small moas lived in New Zealand until the 1700's.

Moas lived in New Zealand when the *Maori,* the Polynesians who settled the country, arrived there about 1,000 years ago. Hunting and the destruction of the moa's lowland forest habitat probably led to the bird's extinction several hundred years later. Some small species of moas may have survived in the mountains on the South Island until the 1700's. Alan Feduccia

Scientific classification. Moas belong to the moa order, Dinornithiformes, and the family Dinornithidae.

Moabite stone. This ancient stone bears some of the earliest writing in Hebrew-Phoenician characters. The stone is of black basalt. It is about 3 feet 8 inches (112 centimeters) high and 2 feet 3 inches (68 centimeters) wide. F. A. Klein, a missionary, found it in 1868 at Dhiban, now in Jordan but formerly in ancient Moab. The writing on the stone was probably carved by a Moabite scribe about 865 B.C. It is a good example of the Hebrew-Phoenician characters used at the time.

When the French in Constantinople wanted to buy the stone, the Arabs of Dhiban broke the priceless, irreplaceable monument into many parts, hoping to get more money by selling the pieces separately. The French collected the larger pieces. A French Embassy official in Constantinople had also made a papier-mâché impression of the stone before it was broken.

The 34-line inscription tells of the deeds of Mesha, king of the Moabites, in his wars against the kings of Israel and against the Edomites. For a description of part of this conflict from the point of view of the people of Israel, see II Kings 3:4-27. The restored stone is in the Louvre, in Paris. William A. Ward

Moat. See **Castle.**

Mobile, *moh BEEL* (pop. 198,915; met. area pop. 540,258), is Alabama's third largest city and its only seaport. Only Birmingham and Montgomery have more people. Mobile lies on the Mobile River where the river flows into Mobile Bay, 31 miles (50 kilometers) north of the Gulf of Mexico (see **Alabama** [political map]).

Mobile is one of the nation's oldest cities. A French-Canadian explorer founded it in 1702 as Fort Louis de la Mobile. He named the fort after the nearby Mobile, or Mabila, Indians, who belonged to the Choctaw tribe. Mobile is called the *City of Six Flags* because six governments have controlled it. France, Britain, and Spain ruled Mobile in the 1700's. Then the United States, the Republic of Alabama, the Confederate States of America, and again the United States flew their flags there.

The city extends west of the Mobile River and covers 158 square miles (409 square kilometers). It is the seat of Mobile County. The Mobile metropolitan area spreads over all of Baldwin and Mobile counties, 2,828 square miles (7,317 square kilometers).

The 34-story First National Bank Building is the tallest structure in downtown Mobile. The Municipal Auditorium and Theater occupies 12 acres (5 hectares) in the center of the city. The Brookley Industrial Complex in southeast Mobile is a former Air Force base.

About 98 percent of Mobile's people were born in the United States. Approximately two-fifths are blacks. Mobile's public schools belong to the Mobile County school system, the largest school system in Alabama. The system has about 50 elementary schools, 20 junior high schools, and 15 senior high schools. There are also many private and parochial schools in the city. Mobile is the home of Spring Hill College, the University of Mobile, and the University of South Alabama.

Mobile has 6 TV stations, 15 radio stations, and 1 daily newspaper—*The Mobile Register.* The Mobile Public Library has five branches and a bookmobile.

Mobile sponsors a symphony orchestra and a small opera company. The Municipal Auditorium and Theater presents such events as America's Junior Miss program, ballet productions, basketball games, circuses, and horse shows. The Mobile Convention Center hosts a variety of activities, including industrial shows and corporate conventions. The city celebrates Mardi Gras each year (see **Mardi Gras**). The Historic Mobile Preservation Society and other groups maintain several homes as they were in the 1800's. Historic aircraft are displayed in Battleship Park, located along Mobile Bay. The park also includes the battleship U.S.S. *Alabama,* which fought in World War II, and the U.S.S. *Drum,* a World War II submarine.

Mobile's Earnest F. Ladd Memorial Stadium is the home of the annual Senior Bowl football game between teams of top college players. Bellingrath Gardens, south of the city, displays flowers, shrubs, and trees from throughout the South. Several streets in Mobile and its suburbs form the 35-mile (56-kilometer) Azalea Trail, where thousands of azalea plants bloom every spring.

Economy of Mobile is based on manufacturing, state and federal government operations, and shipping. The city has over 200 factories. Its largest industry produces paper and wood pulp used for paper. Other products include bakery goods, cement, chemicals, clothing, furniture, naval supplies, paint, rayon, refined oil, and seafood. The major government employers are the U.S. Corps of Engineers and the U.S. Coast Guard.

The Port of Mobile is one of the busiest ports in the Southern United States. It handles large amounts of chemicals, coal, metal products, and petroleum products. Shipyards at the port repair and maintain ships that service the port. In 1985, the Tennessee-Tombigbee Waterway opened Mobile's harbor to about 16,000 miles (26,000 kilometers) of navigable inland waterways (see **Tombigbee River**). The waterway connects the Tennessee River with the Tombigbee River. Five railroads and more than 60 trucking companies provide freight service to Mobile. Amtrak trains stop there. Several bus lines and about 130 steamship firms serve the city. Airlines use Mobile Municipal Airport just outside Mobile. Three tunnels carry traffic under the Mobile River.

Government. Mobile has a mayor-council form of government. The voters elect a mayor and seven council members to four-year terms. Mobile gets most of its revenue from taxes on licenses, property, and sales.

History. Jean Baptiste Le Moyne, Sieur de Bienville, a French-Canadian explorer, founded Fort Louis de la Mobile in 1702. Sieur de Bienville established the fort as a trading post and a French outpost to control nearby Indians. In 1711, river floods forced the colony to move 27 miles (43 kilometers) south to the present site of Mobile.

France gave Mobile to Britain in 1763 after the French and Indian War (1754-1763). Spain captured Mobile in 1780, and the United States seized it in 1813. Mobile was incorporated as a city in 1819.

Mobile became an important seaport during the early 1800's as cotton production flourished in the South. The

Mobile Convention & Visitors Corporation

Downtown Mobile is dominated by the 34-story First National Bank Building, *center.* The Alabama city is an important transportation center.

Battle of Mobile Bay, won by Union forces under Rear Admiral David G. Farragut in the American Civil War, closed Mobile's port in August 1864. The city fell nine months later, the last Southern stronghold to surrender.

The Civil War crippled cotton production in the South, and Mobile suffered economically. However, exports of lumber and naval supplies and imports of general cargo gradually strengthened the city's economy. By the beginning of World War I (1914-1918), Mobile was again a thriving seaport. Between World War I and World War II (1939-1945), Mobile became a shipbuilding and railroad center. In 1940, workers finished building the Bankhead Tunnel. The tunnel carries automobile traffic under the Mobile River. Construction of an Army Air Forces supply base in Mobile during World War II and an expanding paper industry after the war boosted the city to its greatest period of growth. Mobile's population increased from 78,720 in 1940 to 202,779 in 1960.

Mobile's economy suffered again during the 1960's, when the federal government gradually closed Brookley Air Force Base in the city. In 1964, Mobile began Task Force 200, a plan to encourage industrial development in the city. As part of the project, Mobile purchased the abandoned military base in 1969 and created what is now the Brookley Industrial Complex. The city leases buildings and land in the complex to industry. From 1964 to 1969, Task Force 200 expanded Mobile's industrial employment by more than 16,000 jobs.

As in other cities both North and South, public school integration was a major problem in Mobile during the 1960's. Federal court orders forced Mobile to integrate some schools beginning in 1963. As the result of a 1968 U.S. Court of Appeals ruling, the city established widespread school integration in 1970. Many white people then set up private schools for their children.

Mobile rebuilt much of its downtown area during the 1960's. Housing projects and office buildings replaced hundreds of old structures. Two more automobile tunnels under the Mobile River opened in 1975. During the 1980's and 1990's, many new businesses began in Mobile and existing ones expanded. The Mobile Convention Center opened in 1993. John Irvin Sellers

Mobile, *MOH beel,* is a sculpture that achieves its expression through movement. Traditional sculpture achieves its expression through the arrangement of solid, stationary forms. Most mobiles are fragile constructions of rodlike projections that are loosely joined together. Objects of various sizes and shapes are delicately balanced to swing freely in a variety of moving arcs. Sculptors use many materials, textures, and colors for mobiles. A typical mobile includes colored disks, spheres, and wires, or shaped sheets of metal.

Most mobiles are suspended from above, so they can move freely. Some are pivoted on a base. Mobiles usually move as the result of natural air currents. A few are designed to move through mechanical power. Sculptors plan mobiles to present artistic interest not only in their actions, but also in the moving shadows they cast on the walls and the floor.

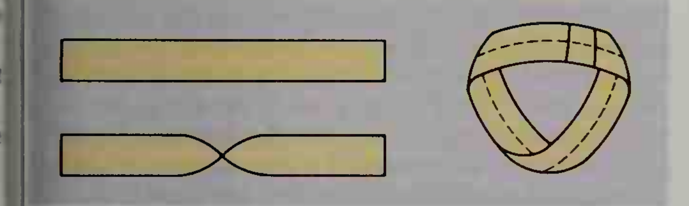
About 1932, American sculptor Alexander Calder became the first artist to create a true mobile, in which movement is the basic aesthetic purpose. French artist Marcel Duchamp first used the word *mobile* to describe the hand-powered and motor-driven sculptures Calder exhibited in Paris in 1932. Deborah Emont Scott

See also Calder, Alexander; Sculpture (Form and treatment; picture: *Red Petals*).

Mobile Bay, Battle of. See Civil War (Battle of Mobile Bay).

Mobile home, *MOH buhl,* is a movable, factory-built house. Mobile homes have built-in wheels. But they usually move only when a truck hauls them to a homesite. Today, mobile homes are designed as permanent, year-round residences. As a result, the term *manufactured home* has begun to replace *mobile home.*

Mobile homes range from 48 to 70 feet (15 to 21 meters) in length and 12 to 28 feet (3.7 to 8.5 meters) in width. They may consist of several units that are joined at the homesite. The houses typically have a living room, kitchen, two or more bedrooms and bathrooms, and closets and cabinets. They are sold equipped with carpeting, draperies, kitchen appliances, and a furnace. Many of them are sold with furniture. The owner may add such features as an air conditioner, an automatic dishwasher, and a garbage disposal unit. A mobile home may rest on blocks, on a concrete slab, or on a



basement. Once installed, the house is connected to electric power, gas, and water supply lines.

In the United States, over 12 million people live in about 6 million mobile homes. Many of the houses stand in mobile-home communities on lots that the residents rent or own. In some neighborhoods, mobile homes occupy lots alongside traditional houses. Mobile homes cost less to own and maintain than do most other houses. In 1976, the United States government set up standards for mobile home construction.

Bruce Butterfield

Mobile River, *moh BEEL,* is a short river that helps drain the delta at the head of Mobile Bay in southwestern Alabama (see **Alabama** [physical map]). The river begins where the Alabama and Tombigbee rivers meet. The Mobile flows southward for about 45 miles (72 kilometers) before it empties into the Gulf of Mexico through Mobile Bay. The river is connected by the Tombigbee River to the Tennessee-Tombigbee Waterway, which opened in 1985. This waterway helps link the port at Mobile with inland ports on the Tennessee and Ohio rivers. The Mobile River provides transportation for coal, wood products, and other cargo. The river was named for the Mobile, or Mabila, Indians who once lived near its mouth. Neal G. Lineback

Möbius strip is a continuous loop with a half-twist in it. You can make a Möbius strip by taking a rectangular strip of paper, turning over one end (twisting it 180 degrees), and joining the ends. Although the original strip had two sides, the Möbius strip has only one. To check this, draw a line down the strip's middle until you reach the place where you started. You will find that the line runs around "both sides" of the strip. Similarly, a Möbius strip has only one edge. If you run your finger along its edge, you will return to your starting place after going around all the edge there is. If you cut the strip "in two" along the line you have drawn, it will remain one loop but will have two sides. The Möbius strip is named after August F. Möbius, the German mathematician who discovered it in the mid-1800's. Mary Kay Corbitt

Mobutu Sese Seko, *moh BOO too SAY say SAY koh* (1930-1997), was president of Zaire from 1965 to 1997. That year, rebel forces overthrew Mobutu, and he fled the country. Rebel leader Laurent Kabila then proclaimed himself president and renamed the country the Democratic Republic of the Congo. The country is also known as Congo (Kinshasa).

For more than 25 years, Mobutu had complete power. Until 1990, Zaire had only one political party, which supported Mobutu's policies. That year, Mobutu announced governmental reforms under which opposition parties were allowed to form. In 1991, a national conference was held to rewrite the Constitution and prepare for multiparty elections. However, Mobutu suspended the conference several times.

In 1991, Mobutu agreed to share power with a prime minister and a cabinet. In 1992, a national conference elected a prime minister, cabinet, and a legislature. However, in 1993, Mobutu dismissed the prime minister and cabinet, and a new prime minister was appointed. But the previous prime minister refused to accept the dismissal. For more details, see **Congo (Kinshasa)** [Recent developments].

Mobutu was born in the village of Lisala, in what was then called the Belgian Congo. He served in the Belgian colonial army from 1949 to 1956. In June 1960, the Belgian Congo became an independent nation with the name Congo. In July, Mobutu became chief of staff of his country's army. He took control of the government in September, after disputes between civilian leaders began. Mobutu returned control of the government to civilians in February 1961. Left-wing rebellions began in Congo in 1964. In November 1965, Mobutu took control of the government again and became president. In 1971, Congo was renamed Zaire.

Mobutu's original name was Joseph Désiré Mobutu. In 1972, he adopted the name Mobutu Sese Seko, shortly before he ordered all people in his country who had European names to adopt African names.

Moby-Dick. See **Melville, Herman.**

Moccasin, *MAHK uh suhn,* is a soft, slipperlike shoe originally worn by North American Indians. The Indians made moccasins from the skin of deer and other animals and decorated them with beads or porcupine quills. These shoes had no heels and were closely fitted. Most were of ankle length. Others extended to the knee.

The term *moccasin* also refers to a shoe construction. Genuine moccasins were made of a single piece of leather forming the bottom and sides of the shoe. A second piece, called the *plug,* formed the top of the shoe. In modern forms of moccasins, the sole may have more than one piece of material for greater protection and longer wear. Ruth Schachter

Moccasin flower. See **Lady's-slipper.**

Moccasin snake. See **Water moccasin.**

Moche, *MOH chay,* was an American Indian culture that flourished in the coastal desert of what is now northern Peru from the A.D. 100's to the 700's. The Moche people are known especially for their crafts and artwork, which include pottery, murals, textiles, and precious metal objects. The people are sometimes called the *Mochica.*

The Moche used molds to shape their pottery, which they painted. The most commonly used paints were reddish-brown, cream-colored, and black. Paintings on the pottery include portraits, scenes of daily life, and pictures of religious ceremonies. Some Moche murals consist of geometric designs. Others show scenes from Moche ceremonies and myths. The Moche wove both cotton and wool textiles and made jewelry and other objects of copper, gold, and silver.

At Sipán, Peru, near Chiclayo, archaeologists have uncovered the graves of Moche who were buried with gold, silver, and other precious objects. These Moche individuals held high social rank, and they may have

Nathan Benn

played important roles in religious ceremonies.

The Moche used irrigation to grow corn and other crops. They traded extensively with peoples of the western Andes Mountains. Alexandra M. Ulana Klymyshyn

See also **Indian, American** (Indians of the Andes).

Mock orange is the name of a group of shrubs native to North America, eastern Asia, and Europe. Garden species are sometimes called *syringas.* Mock orange plants are covered with small, white or cream-colored flowers that may grow singly or in clusters. The flowers of some species have purple spots at the base of the petals. In most species, the flowers are fragrant, but some species have odorless flowers. The plants generally reach a height of no more than 10 feet (3 meters), but a few species may grow 15 feet (4.5 meters) high.

Mock oranges generally bloom in late spring, often for only a few weeks. Breeders have produced many hybrids of mock oranges. Fred T. Davies, Jr.

Scientific classification. Mock oranges belong to the saxifrage family, Saxifragaceae. They make up the genus *Philadelphus.*

Mockingbird is the name of more than 30 species of birds native to the Western Hemisphere. The *northern mockingbird,* also called *common mockingbird* or simply *mockingbird,* is famous for its ability to imitate the sounds of other birds. One naturalist reported a northern mockingbird that imitated the songs of 32 different birds in 10 minutes. The bird's own song is one of the most versatile birdsongs. The bird lives throughout the United States and Mexico and in parts of Canada.

The northern mockingbird has an ashy-white breast and an ash-gray coat. Its wings and tail are darker gray with white markings. Males and females have almost the same coloring, but the female has a little less white. The mockingbird grows from 9 to 11 inches (23 to 28 centimeters) long. It has a long slender body and tail.

Mockingbirds build their nests in thickets, low trees, and bushes. They lay from four to six greenish-blue or bluish-white eggs spotted with brown. Mockingbirds

Hal H. Harrison from Grant Heilman

A mockingbird feeds its young insects and seeds. Mockingbirds can imitate the songs of many kinds of birds.

help people by eating insects and weed seeds. They often pick insects off the radiators of parked cars. They also eat wild fruits and can damage fruit crops. The birds can be aggressive, especially when nesting.

Donald F. Bruning

Scientific classification. Mockingbirds belong to the mockingbird family, Mimidae. The scientific name for the northern mockingbird is *Mimus polyglottos.*

Mode, in statistics, is that value in any group that occurs most frequently. Suppose a boy counts the eggs in 77 birds' nests. He finds that 4 nests have 1 egg each, 65 have 2 eggs each, 5 have 3 eggs, and 3 have 4 eggs. The nests that contain 2 eggs are by far the most common. Thus, 2 is the *mode,* or *modal value,* in this group. The mode is a type of *average* that is often useful in the study of statistics. See also **Average; Mean; Median; Statistics** (Probability). Doris F. Hertsgaard

Model . . . See articles on models listed under their key word, as in **Airplane, Model.**

Model Parliament was the name given in the 1800's to the parliament that met at Westminster, in England, in 1295. When Edward I of England ordered the parliament to meet, he summoned not only churchmen and nobles, but also two knights elected from each county and two townsmen from each of many towns. For this reason, the parliament was considered representative of early assemblies from which today's British Parliament gradually emerged. But research indicates that knights and townsmen had been summoned before 1295, and some later parliaments included only nobles and churchmen. See also **Parliament.** John Gillingham

Modeling. See **Sculpture** (The sculptor at work).

Modeling is a profession in which people display clothing and other products or illustrate various situations. Models of all ages pose for photographers and painters and work in fashion shows and exhibits.

Kinds of models. Different kinds of models specialize in a variety of assignments, but any model may work in more than one field. *Fashion models,* wearing the latest styles of clothing, jewelry, and accessories, pose for photographs that appear in magazines, newspapers, and catalogs. These models also display clothes in stores and fashion shows. *Commercial models* help sell many kinds of products in stores and wholesale showrooms and at exhibits and trade shows. They also appear in advertisements and television commercials.

Many publications hire *illustration models* to appear in pictures with articles and stories. *Artist's models* pose

for art classes and individual artists. Clothing designers and patternmakers employ *fitter's models* for fitting clothes in all sizes in which the garments will be made.

Physical requirements for modeling. A model's basic requirement is physical attractiveness. A woman need not be beautiful, nor a man handsome, to be a model. But a model must appear desirable according to the ideal of the time. In addition, he or she should be well groomed and graceful. A youthful appearance is necessary for most modeling, especially fashion modeling.

Size is vital in fashion work. Most fashion models are young women who wear a size 8 or 10 dress. A female model should be at least 5 feet 8 inches (175 centimeters) tall to display clothes to their best advantage. Most male models wear a size 40-regular suit and are at least 6 feet (183 centimeters) tall. A fitter's model must have the exact dimensions required for a standard size. Height is not as important for illustration models or for models who specialize in modeling such items as jewelry or shoes. They must have well-proportioned hands, legs, and feet. *Photographic models,* who pose for the camera, must be thin to appear attractive on film.

A model's work. Modeling may seem glamorous and exciting, but it is difficult, demanding work. Models sometimes work for long periods under hot, bright lights. Advertisers plan ads far in advance, and so models may be required to pose in bathing suits in winter and in heavy coats during the summer. A model must be able to follow directions, and must have some acting ability in order to portray any mood desired by a client.

A model who is photographed earns an hourly fee for his or her time. But for a fashion show, a model may work for a specific fee. Artist's models charge lower fees because artists operate on smaller budgets and their work requires more time. The fees of models who perform in TV commercials are determined by contracts with the television and motion-picture actors' unions.

Models are photographed at a photographer's studio. Photographs also may be taken *on location* in other buildings, outdoors, or in another city or country.

Model agencies represent models in dealing with clients. An agency accepts assignments for a model, sends bills to clients, and collects money owed the model. The agency receives a percentage of the model's earnings as a commission. Successful models are registered with a licensed model agency.

A client arranges with an agency to hire a model for a certain length of time on a particular day. This arrangement is called a *booking.* The booking may be for appearing in a fashion show, making a TV commercial, or posing for a photographer or artist.

Careers. Modeling is a highly competitive field, and most models have only a short career because a youthful appearance is so important. With the growing interest in the concerns of older people in the United States, some models are now able to work for many years. Nevertheless, the average modeling career still lasts only one to three years.

Employers generally prefer models who have had training or actual experience in the field. A man or woman who wants to become a model can attend modeling and self-improvement classes. These classes teach such skills as poise, grooming, the use of makeup, and

© Larry Day

Models pose for a photographer, who positions them for a fashion advertisement. Although modeling may seem to be glamorous, it requires hard, tiring work and long hours.

the selection of attractive clothing and accessories. Courses in dance, drama, and speech are also useful.

Most models are selected for a particular assignment on the basis of their *portfolio.* A model's portfolio consists of a series of photographs that show him or her in a variety of poses with different facial expressions. Female models also pose wearing a variety of hairstyles. Models also give potential clients a short series of photos called a *composite.* A composite includes a model's height and other physical characteristics and the name of the agency to contact.

In the United States, most modeling activity takes place in Atlanta, Chicago, Dallas, Los Angeles, and New York City. New York City is the center of most national advertising, and professional models find their best opportunities there. Modeling jobs are available in certain small cities, but most of the assignments outside large metropolitan areas involve only part-time work.

Some successful models become identified with a single company or product. A few gain fame as celebrities and personally endorse certain products. A large number of people have used a modeling career as a stepping stone to some other interesting professions. These former models are employed in such fields as advertising, fashion merchandising, public relations, publishing, and retail buying. Models who make TV commercials gain experience that can be helpful for an acting career in television or the movies. This experience can also lead to executive positions in various areas of the entertainment field.

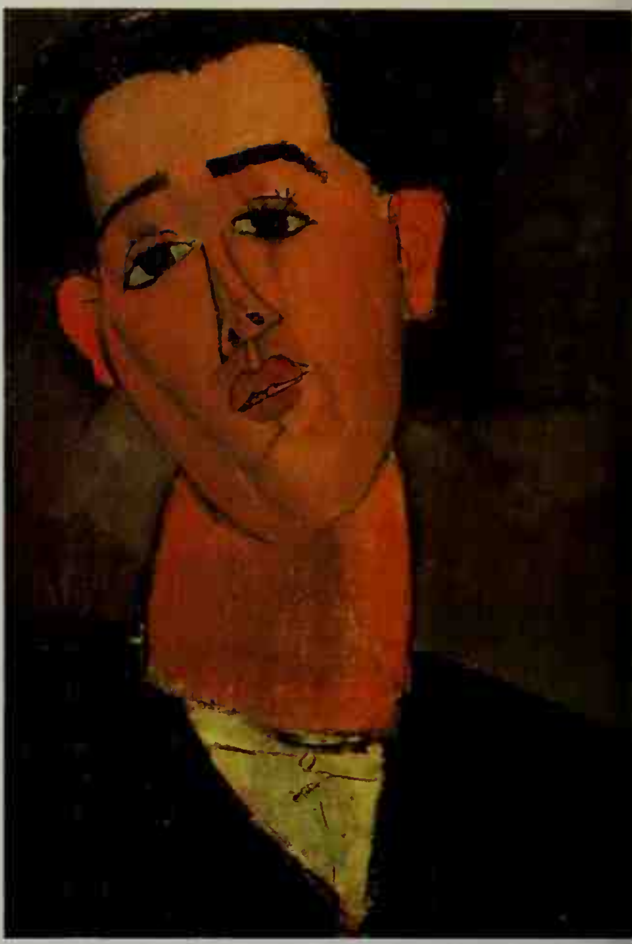
Modem, *MOH duhm,* is a device that enables computers to transmit and receive information over the telephone network. The word *modem* stands for *mod*ulator-*dem*odulator. A modem *modulates* (translates) a computer's digital electrical signals into tones that can travel over telephone lines. A modem at the other end *demodulates* (retranslates) the tones back into computer information. Modems can send and receive not only text information, but also sound, still pictures, and moving pictures.

Modems and telecommunications software make it possible for computer users throughout the world to communicate with each other. To begin this communication, a modem first sends a signal representing a telephone number. The telephone network directs the transmission to the device represented by that number. Communication can take place directly with another computer's modem, or through the vast computer network called the Internet (see **Internet**).

The faster a modem works, the easier it is to receive complex information. Modem speed is measured in units called *bits per second* (bps). Speedy, inexpensive modems available to home computer users helped bring about an explosion of online communications in the middle and late 1990's. Keith Ferrell



Moderate Republican. See **Reconstruction** (The radicals and the moderates).

Modigliani, *moh* DEE *lee AH nee,* **Amedeo,** AH *meh DEH oh* (1884-1920), was an important Italian artist of the early 1900's. His favorite subject was the single figure. He painted many portraits. Modigliani's other favored theme was the reclining female nude.

Modigliani was a brilliant draftsman, and his creative use of line is a notable aspect of his style. He preferred oval and cylindrical forms. Most of his subjects have elongated bodies, long necks, and oval heads. The simplification and distortion of the figures in his paintings, drawings, and sculptures show his interest in black African sculpture. The elegance of his creations also suggests the influence of his friend, the sculptor Constantin Brancusi. Even though Modigliani's portrait subjects were molded by his recognizable style, they retain their individuality.

Modigliani was born in Livorno. He settled in Paris in 1906. He was a colorful and restless character whose early death was linked to alcohol and drug abuse.

Pamela A. Ivinski

A typical Modigliani portrait shows a single figure with a long neck and little expression against a simple background.

Modoc Indians, *MOH dahk,* are a small tribe closely related to the Klamath Indians. Until the 1860's, the Modoc lived at the California and Oregon border, mainly in the Lost River Valley and around Tule Lake. In winter, they lived in shelters that were partly underground. In warm months, they lived in wood houses covered with mats made from tall marsh plants called *tules.* They also used tules to make rafts, baskets, and shoes. The Modoc fished, hunted, and gathered wild vegetables for food. Modoc leaders came from wealthy families, but the tribe made political decisions at assemblies where everyone was permitted to speak.

In 1864, the United States government relocated the Modoc tribe to the Klamath Reservation in Oregon. Kintpuash, a Modoc leader also known as Captain Jack, could not tolerate the reservation and returned home with part of the tribe. In 1872, the United States Army tried to force them to return to the reservation. The tribe fled to an area near Tule Lake. From there, about 60 Modoc warriors fought off more than 1,000 soldiers for five months. The Army eventually defeated the Modoc, executed their leaders, and exiled most of the tribe to Oklahoma.

Today, about 200 Modoc live in Oklahoma. The site of the Modoc war with the Army is now Lava Beds National Monument in California. Victoria D. Patterson

Moebius strip. See **Möbius strip.**

Moffat Tunnel, *MAHF uht,* is one of the longest railroad tunnels in the world. It cuts through James Peak in Colorado for 6.23 miles (10.03 kilometers).

Moffat Tunnel has two separate *bores* (tubes). The largest, 24 by 16 feet (7 by 5 meters), is used for trains. The other bore, 8 by 8 feet (2.4 by 2.4 meters), carries water from the Fraser River to Denver.

Engineers bored through rock from each side of the Continental Divide, at an elevation of 9,200 feet (2,800 meters). The tunnel shortened the distance between Salt Lake City and Denver by 176 miles (283 kilometers). By using the tunnel, trains avoid snowstorms, snowslides, and steep grades. The tunnel was named for David H. Moffat, American banker and railroad builder. It was leased to the Denver & Salt Lake Railroad.

Boyd C. Paulson, Jr.

Mogadishu, *MAW gah DEE shoo* (pop. 750,000), is the capital and largest city of Somalia. Mogadishu, sometimes spelled *Mogadiscio,* is also the country's chief port. It is located about 140 miles (225 kilometers) north of the equator on the southeast coast of Somalia, which borders the Indian Ocean. For location, see Somalia (map).

Mogadishu has Arab- and Western-style buildings. Its modern harbor handles many of Somalia's exports, including bananas, cattle, and hides. The city's chief industries process foods.

Historians believe that Arabs founded Mogadishu in the 900's. Arab sultans ruled the city for centuries. Italy gained control of the city in 1889 and later made it the capital of the colony of Italian Somaliland. The Italians built the city's central section. In 1960, Italian Somaliland and neighboring British Somaliland became the independent state of Somalia, with Mogadishu as its capital. In 1991, much fighting took place in Mogadishu between government forces and rebels. The city suffered heavy damage. Stephen K. Commins

Mogollon, *moh guh YOHN,* is the name of prehistoric Indians who lived in southeastern Arizona and southwestern New Mexico from about 500 B.C. to A.D. 1200. Scientists believe they disappeared about A.D. 1250. The early Mogollon lived in villages of pit-houses. Later, they built crude one-story pueblo villages. The Indians gathered wild berries and seeds and later hunted and farmed corn. They used crude stone tools. The Mogollon made tobacco pipes of stone or baked clay. They decorated pottery with figures and geometric designs in red and brown or black and white. The pottery of the Mimbres people, a branch of the Mogollon, was among the finest made anywhere in North America north of Mexico. Alfonso Ortiz

Mogul Empire. See Mughal Empire.

Mohair is the name given to the hair of the Angora goat. This animal is native to Asia Minor and also is raised in South Africa and the United States. The name *mohair* is also applied to the lustrous, long-wearing fabrics produced from the hair of the Angora goat.

Mohair is smooth and resilient. It is often blended with other fibers. In many blends, mohair gives the surface of the fabric a glossy appearance. Mohair is often used to make decorative fabrics, draperies, and clothing, especially summer suits. It is also used in fabrics that must withstand rough wear, such as furniture upholstery. Robert A. Barnhardt

Mohammad. See Muhammad.

Mohammad Reza Pahlavi, *moh ham AD reh ZAH pah lah VEE* (1919-1980), was the *shah* (king) of Iran from 1941 to 1979. He was overthrown in 1979 by a mass movement of Iranians led by Ayatollah Ruhollah Khomeini, a Muslim religious leader. As shah, Mohammad Reza carried out many economic and social reforms. But they did little for most Iranians, and he was a dictatorial ruler. Alternate spellings for parts of his name include *Mohammed, Muhammad, Riza,* and *Pahlevi.*

Mohammad Reza was born in Tehran. He succeeded his father, Reza Shah Pahlavi, as shah. Reza had refused to cooperate with the Allies during World War II (1939-1945), and they forced him to abdicate. After Mohammad Reza became shah, he let the Allies keep troops in Iran and send supplies through Iran to the Soviet Union.

Beginning in the mid-1940's, the shah's authority was challenged by Iranian Communists and by nationalists led by Mohammad Mossadegh. In 1951, the nationalists forced the shah to appoint Mossadegh prime minister. Continuing opposition forced the shah to leave Iran in 1953. But with American help, Mossadegh was ousted, and the shah became Iran's most powerful leader.

In the 1960's, the shah began a program to distribute land to some peasant farmers. In the 1960's and 1970's, he used part of Iran's oil revenue to promote social and economic development. He expanded programs dealing with literacy and health care, and built many schools, airports, highways, railroads, dams, and irrigation facilities. In addition, he bought much military equipment. Economic change led to rapid migration from rural areas to cities and increased the income gap between rich and poor.

Although Iran had a parliament and a cabinet, the shah controlled the government. His vast power aroused much opposition, especially from students, intellectuals, religious leaders, and industrial workers. His critics accused him of denying freedom of speech and other rights and of using secret police and military force to silence opponents. They also claimed his spending policies and government corruption were ruining Iran's economy. A large number of conservative Muslims said some of his policies violated teachings of the Muslim religion.

In January 1979, during the mass movement against him, the shah left Iran. His government was overthrown in February. While living in Mexico, the shah became ill. In October 1979, he was admitted to a hospital in the United States. In November, Iranian revolutionaries took over the United States Embassy in Tehran. They held as hostages a group of U.S. citizens, most of whom worked for the embassy. They said they would not release the hostages unless the U.S. government returned the shah to Iran for trial. The government refused to do so. The shah moved to Panama in December 1979 and to Egypt in March 1980. He died in Egypt in July 1980. The hostages were released in January 1981. Nikki R. Keddie

Mohammed. See Muhammad.

Mohammedanism. See Islam; Muslims.

Mohave Desert. See Mojave Desert.

Mohave Indians, *moh HAH vee,* are a tribe who live in California, Arizona, and Nevada along the Colorado River. Traditionally, the Mohave lived in isolated groups of related families. They built houses made of a frame of logs and poles thatched with plant material and covered with sand. Some houses were large enough for many families to live together.

The Mohave farmed the rich soil created by the spring flooding of the Colorado River. They planted corn, beans, pumpkins, melons, and wheat. They also fished in the river with nets or basketry scoops, hunted, and gathered wild plants.

The Mohave thought of themselves as a single nation within a defined territory. Unlike many other California tribes, whose small villages had little involvement with other villages of the same tribe, the Mohave moved freely from one settlement to another throughout the territory. They had hereditary chiefs, but such positions

as war leader and *shaman* (spiritual leader or doctor) went to individuals believed to have received special powers in dreams. In the Mohave religion, knowledge and power came from dreams.

In the late 1700's, there were about 3,000 Mohave Indians. According to the 1990 United States census, there are about 1,400 Mohave. Most live either on the Fort Mohave Reservation near Needles, California, or south of Parker, Arizona, on the Colorado River Reservation.

Victoria D. Patterson

Mohawk Indians are a tribe of Iroquois Indians who once occupied an area near the Mohawk River in central New York. Today, most of the tribe's approximately 10,000 members live in Canada. More than a fourth live on the Six Nations Indian Reserve near Brantford, Ontario. Other Mohawk live in New York.

Mohawk warriors were known for their fierceness and skill in battle. The term *Mohawk* comes from an Indian word that means *they eat living things.* Mohawk men hunted bear, deer, and other animals. Mohawk women raised corn, beans, and squash and gathered nuts, berries, and edible plants. The Mohawk lived in large bark-covered dwellings called *longhouses.*

The Mohawk were one of the five tribes that, by the early 1600's, had joined together to form an organization known as the *Iroquois League* or the *Five Nations.* The other tribes were the Cayuga, Oneida, Onondaga, and Seneca. No one knows exactly when the league was formed. About 1722, the Tuscarora joined the league, which then became known as the *League of the Six Nations.* The Mohawk's land made up the easternmost part of the Iroquois territory.

The league became divided over which side to support during the Revolutionary War in America (1775-1783). The Mohawk and three other Iroquois tribes supported the British, largely because of the influence of a Mohawk leader named Joseph Brant (see **Brant, Joseph**). After Britain lost the war, many Mohawk and other Iroquois moved to Canada. Some Mohawk took up new occupations, including craftwork and lumberjacking. Since the late 1800's, many Mohawk have specialized in construction work on skyscrapers and bridges.

In recent years, the Mohawk have been involved in several disputes over land claims and other matters. In 1990, a land dispute broke out between some Mohawk and residents of the town of Oka, Quebec, near Montreal. An armed Mohawk group blocked access to the disputed land in March. This action led to a stand-off with police and Canadian armed forces that lasted until late September, when the last of the Mohawk group surrendered. Other Mohawk, acting in sympathy, blockaded a major bridge over the St. Lawrence River from July to early September. In 1997, the Canadian government purchased the disputed land and turned it over to the Mohawk. The government also promised to discuss issues concerning treaty rights and the funding of social programs for the Mohawk. Robert E. Powless

See also **Iroquois Indians**.

Mohawk River is the largest tributary of the Hudson River. The Mohawk rises in central New York, about 20 miles (32 kilometers) north of Rome. It flows southeast for 148 miles (238 kilometers) and enters the Hudson River about 10 miles (16 kilometers) north of Albany.

The Mohawk River was named for the Mohawk Indians who lived in the west part of the Mohawk Valley. The valley has served as a transportation route from the Hudson Valley to the Great Lakes region since colonial days. Two railroads, a highway, and the main branch of the New York State Barge Canal System run along the Mohawk for much of its length. Michael K. Heiman

Mohawk Trail was a route westward along the Mohawk River from the Hudson River to the Great Lakes. The Iroquois Indian confederacy, a league of Indian tribes that included the Mohawk Indians, occupied the land it crossed. In pioneer days, thousands of settlers traveled westward along this route. Its importance declined after the building of the Erie Canal in 1825. A railroad and a modern highway now follow the course of the trail. Robert E. Powless

Mohegan Indians became a powerful tribe in New England during colonial times. They lived along the Thames River in Connecticut, and the name *Mohegan* refers to the tides of the Thames near the Connecticut coast. The Mohegan are often confused with the Mohican, a tribe invented by the American writer James Fenimore Cooper in his novel *The Last of the Mohicans.*

The Mohegan Indians formed part of the Pequot tribe until the Pequot War broke out in New England in 1637. The Mohegan then helped the New England colonists destroy the Pequot. The Mohegan chief, Uncas, remained friendly with the colonists and helped them in other Indian wars. In turn, the colonists supported the Mohegan in their disagreements with other tribes.

During the 1700's, white settlers in Connecticut gradually forced the Mohegan Indians off much of their land. Large numbers of Mohegan also died from diseases introduced by whites. In 1775, many of the remaining Mohegan joined a mixed group of Christian Indians in a community in New York called Brotherton. In the 1820's, the federal government moved these Indians to Wisconsin. Today, their descendants live on the Stockbridge Reservation in northeastern Wisconsin. Some descendants of the Mohegan still live in Ledyard and North Stonington, Connecticut. T. Brasser

Mohican Indians. See Mohegan Indians; Mahican Indians.

Moi, Daniel Toroitich arap (1924-), became president of Kenya in 1978. He had been vice president from 1967 until 1978. He became president when Jomo Kenyatta, Kenya's first president, died. As president, Moi promoted good relations with the United States and other Western nations during the Cold War.

Early in Moi's presidency, his Kenya African National Union (KANU) was the only political party in Kenya, though other parties were not banned by law. But after an unsuccessful coup against him in 1982, Moi backed a change in the Constitution that made KANU the only legal political party. The one-party state led to protests by Kenyans, and threats by Western na-

Daniel T. arap Moi

tions to stop financial aid to Kenya. In 1991, the Constitution was amended to allow for a multiparty system. Elections were held in December 1992, and Moi was elected president by the voters. He was reelected in 1997.

Moi was born near Nakuru, Kenya. He worked as a schoolteacher from 1945 to 1957. Moi was active in the negotiations that led to Kenya's independence from Britain in 1963. Stephen K. Commins

Moiré pattern, *mwah RAY* or *maw RAY,* is a pattern of lines formed when two regularly spaced patterns overlap but are not aligned. For example, the illustration with this article shows the moiré pattern produced by two misaligned, overlapping patterns of circles. In this case, lines seem to stream from the center of the figure.

The word *moiré* comes from the name of a ribbed fabric made since the 1400's. Overlapping pieces of silk

Edmund Scientific Co.

A moiré pattern of wide curving lines results where two groups of narrow-lined circles overlap.

or window screens often produce moiré patterns. Many *optical art,* or *op art,* paintings also have moiré patterns. The patterns create an illusion of shimmer, as though some hidden feature of the paintings were vibrating.

Scientists use moiré patterns to detect abnormalities in surfaces and motions, because any change in a moiré pattern is highly magnified. For example, a slight movement of one circle in the illustration would noticeably change the moiré pattern. Jearl Walker

Mojave Desert, *moh HAH vee,* in southeastern California, is a vast desert wasteland covering about 25,000 square miles (64,700 square kilometers). It is sometimes spelled Mohave. It lies between the Sierra Nevada and the Colorado River (see **California** [physical map]). The Pacific Ocean once covered this region. Over a long period, high mountains rose and blocked the entry of water from the sea. Volcanic mountains erupted and covered the region with lava, mud, and ashes. Today, many small isolated mountain ranges and extinct volcanoes break up the great stretches of sandy soil. Dry lake beds form the world's chief source of boron, a mineral used for fuels and nuclear reactors. John Edwin Coffman

Molasses is a thick, sweet, sticky syrup. It is yellowish or dark brown. Molasses is used for brewing, cooking, candymaking, and distilling alcohol, and as a livestock feed.

Most molasses is obtained as a by-product in the manufacture of sugar from sugar cane. Therefore, countries that grow sugar cane produce most of the world's molasses (see **Sugar cane**). In the United States, Florida and Hawaii are centers of molasses production.

Molasses is the liquid that remains after sugar crystals are removed from concentrated cane juice. Molasses may be made by the *open kettle method* or by the *vacuum pan method.* In the open kettle method, the cane juice is boiled in a large open pan. After it has been boiled several times, most of the water evaporates. The syrup that remains receives additional boiling until it becomes a stiff mass of syrup and crystals called *massecuite.* The massecuite is placed in barrels with tiny holes in the bottom. The molasses seeps through these holes, leaving sugar crystals inside the barrels.

Large sugar factories generally use the vacuum pan method, in which the massecuite is boiled in large, covered vacuum pans. After being boiled several times, it is thoroughly stirred in a mixer. The mixture is then spun in rotating containers called *centrifuges.* The centrifuges have walls of fine copper mesh that permit the molasses to pass through but hold the sugar crystals.

Further boiling of the molasses produces varying grades. The molasses left after several boilings is called *blackstrap.* It is used in fertilizer and is commonly mixed with hay to serve as feed for farm animals. The distillation of molasses produces ethyl alcohol, which is used in the chemical industry and as a combustion fuel. Molasses is also distilled to make rum. Paul H. Moore

Molasses Act was a British law passed in 1733 to change a pattern of trade in the American Colonies. It placed a duty of sixpence on each gallon of molasses imported into British colonies from areas not ruled by Britain, and also put duties on imported sugar and rum. Molasses was used to make rum, and New England had a rich rum industry. Because of lower prices, the New Englanders bought more rum in the French West Indies than in the British West Indies. Planters in the British West Indies thus requested duties on molasses in hopes of curbing the trade with the French. But New England smugglers avoided paying the duties. Pauline Maier

Mold is a hollow form. See **Cast and casting.**

Mold is a type of fungus that often grows on food. Like mushrooms, mildews, and all other fungi, molds have no *chlorophyll*—the green coloring matter that plants use to manufacture food. Molds live on food made by plants or animals, or on decaying matter. Some molds live as parasites on animals, plants, or other fungi.

Many common molds can grow on bread, fruit, and other food. The *black bread mold* often forms a cottony, soft, white growth on damp bread. The mold gets its name from the dark-colored *spores* (tiny reproductive bodies) that it soon produces. A group of molds known as the *blue molds* also may grow on bread. A green mold often grows on various kinds of cheeses. Other molds, called *water molds,* are found in water and soil.

Molds develop from spores. When a spore of the black bread mold settles on damp food, it swells and begins to grow by producing tiny *hyphae* (threads). The

hyphae form a tangled mass called a *mycelium,* which in turn produces aerial hyphae called *stolons.* Rootlike structures known as *rhizoids* anchor the stolons in the food.

As the black bread mold matures, many upright *fruiting bodies* form above the rhizoids. Each fruiting body has a spore case, called a *sporangium,* at its end. A sporangium looks like a miniature pinhead and contains thousands of spores. When the spore case matures and breaks open, the spores are carried away by air currents. These spores may settle on damp foods and grow, starting the reproductive cycle over again. Some molds, such as *penicillium,* produce chains of spores at the tips of certain hyphae, called *conidiophores.*

Moldy foods generally should be thrown away. But certain cheeses, such as Roquefort, owe their flavor to a mold that grows in them and ripens them. Molds are also useful because they fertilize soil by breaking up dead organisms and waste material. *Penicillium* molds produce the drug penicillin (see **Penicillin**).

Joe F. Ammirati

Scientific classification. Molds belong to the division Eumycota in the kingdom Fungi. They are in the classes Hyphomycetes, Oomycetes, and Zygomycetes.

See also **Fungi; Mildew; Mycotoxin; Slime mold.**

Moldavia. See **Moldova; Romania** (Land regions).

Moldova, *mawl DOH vuh,* is a country in southeastern Europe. It is bordered by Romania on the west and by Ukraine on the other three sides. Chisinau is Moldova's capital and largest city.

From 1940 to 1991, Moldova was a republic of the Soviet Union. It was called the Moldavian Soviet Socialist Republic, or simply Moldavia. With the collapse of the Soviet Union in 1991, the republic declared its independence and changed its name to Moldova.

Moldova belonged to Romania before it became part of the Soviet Union. Moldova has especially close ties with a region in eastern Romania that is still called Moldavia. For much of their history, Moldova and the Romanian region of Moldavia were united.

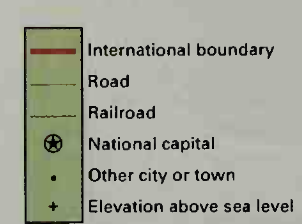
Government. Political power in Moldova is divided between a president, Parliament, and a Council of Ministers that is headed by a prime minister. Voters elect the president to a four-year term. Parliament has 101 members, who are also elected to four-year terms.

Parliament elects the prime minister. The prime minister, with the approval of Parliament, selects the members of the Council of Ministers. The council members assist the prime minister in carrying out the functions of the government.

The largest political party is the Moldovan Communist Party. Other major parties include the Party for a Democratic and Prosperous Moldova and the Moldovan Party of Democratic Forces. The Democratic Convention of Moldova is an alliance of right-wing parties.

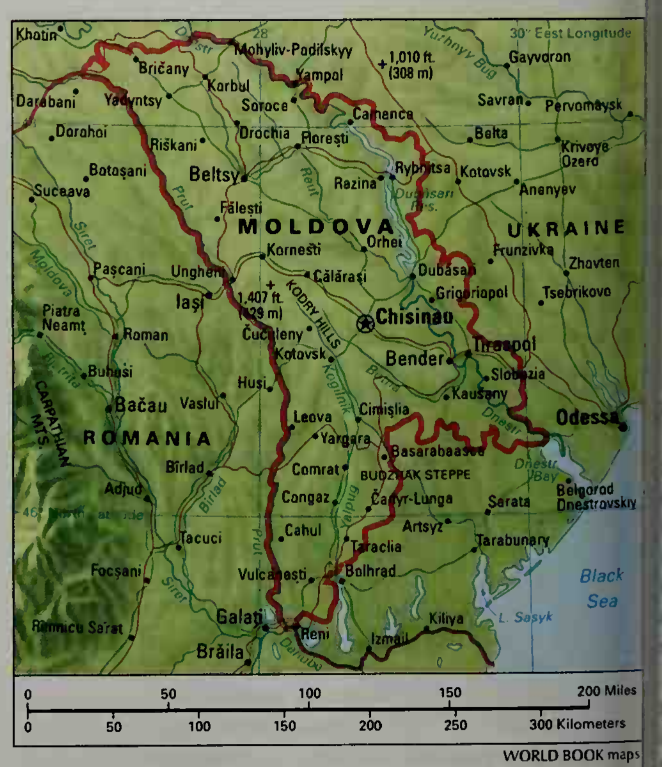
People. About two-thirds of the country's people are ethnic Moldovans. Most of the rest of the population is made up of Russians; Ukrainians; Gagauz, a Turkic people; and Bulgarians.

More than half of Moldova's people are rural dwellers. They live clustered in villages, and most of them work as farmers. The official language of the country is Moldovan, which differs little from Romanian. Most Moldovans are Eastern Orthodox Christians.



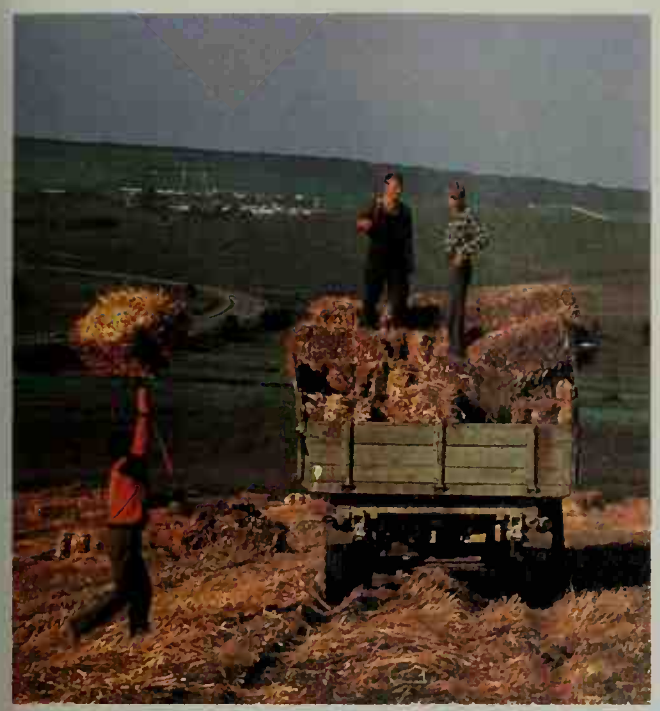
Moldovan children are required to attend school from the ages of 6 to 18. Almost every Moldovan 15 years of age or older can read and write. The Moldovan State University is located in Chisinau. The Academy of Sciences in that city oversees the workings of about 30 academic institutes.

Land and climate. Most of Moldova consists of hills broken by river valleys. The highest elevations are in the scenic forests of the central region. The country's tallest



Facts in brief

Capital: Chisinau.
Official language: Moldovan.
Official name: Republica Moldova (Republic of Moldova).
Area: 13,012 mi² (33,700 km²). *Greatest distances*—north-south, 210 mi (340 km); east-west, 165 mi (265 km).
Elevation: *Highest*—Mount Balaneshty, 1,407 ft (429 m). *Lowest:* Dnestr River at southeastern border, 80 ft (25 m).
Population: *Estimated 2002 population*—4,383,000; density, 337 per mi² (130 per km²); distribution, 54 percent rural, 46 percent urban. *1989 census*—4,337,592.
Chief products: *Agriculture*—eggs, grain, grapes, milk, sugar beets. *Manufacturing*—construction materials, refrigerators, tractors, washing machines.
National anthem: "Deşteapta-te, Române" ("Romanian, Arise").
Money: *Basic unit*—leu. One hundred bani equal one leu.



Moldova

WORLD BOOK maps

A. Boulat, Sipa Press

Farmers load bales of hay, which will be used as feed for cattle. Moldova's economy is based largely on agriculture. Rich soil for farming covers three-fourths of the country.

peak is Mount Balaneshty, which rises 1,407 feet (429 meters) in the Kodry Hills in west-central Moldova. Lush uplands and *steppes* (grassy plains) cover much of northern and eastern Moldova. A large plain stretches across the southern part of the country.

Moldova has more than 3,000 rivers, but only 8 are longer than 60 miles (95 kilometers). The main waterway is the Dnestr River, which flows through eastern Moldova. The Prut River flows along the country's western border, which separates Moldova from Romania.

Rich, black soil that is good for farming covers three-fourths of the country. In the north and along the Dnestr, where the most fertile soils are, farmers grow sugar beets, fruits, and some grain. Less rich soils in the southern part of the country are used for growing corn, sunflowers, and wheat.

The animals found in Moldova include badgers, wild boars, Siberian stags, and wolves. The rivers hold carp, perch, and pike. Such animals as foxes, hares, and muskrats are hunted for their fur.

Temperatures average about 25 °F (−4 °C) in January and about 70 °F (21 °C) in July. The average annual precipitation provides about 20 inches (50 centimeters) of rain, snow, and other forms of moisture.

Economy. Moldova has a developing economy based mainly on agriculture. The central and southern regions produce grapes for wine. Farms in the south also grow corn and winter wheat. The northern and central regions have fruit orchards and fields of grain. Moldova's other crops include sugar beets, sunflowers, and tobacco. Dairy farming, and hog and cattle raising are also important to the economy.

Moldova's chief industries process food and other agricultural products and manufacture agricultural machinery, construction materials, refrigerators, television sets, and washing machines. The country has plants for canning produce, refining sugar from sugar beets, and making wine. Other plants process furs and manufacture footwear and silk and woolen garments.

Moldova's chief trading partners are former Soviet republics, especially Russia and Ukraine; and other countries of Eastern Europe. Its major exports include clothing, fur, leather, and wine. Its main imports include automobiles, electronic items, and fuel.

History. From about 700 B.C. until about A.D. 200, the region that is now Moldova was under the control of Iranian peoples from central Asia—first the Scythians and later the Sarmatians. From about A.D. 200 until the A.D. 1200's, various other peoples from the west and east invaded and ruled the area. These invaders included the Goths, Huns, Avars, and finally the Mongols (also called the Tatars).

The people of Moldova gradually united, and by the mid-1300's, they formed an independent state under a single ruler, a prince. The state was called the principality of Moldavia. It included present-day Moldova, then called Bessarabia, and an area between the northern Carpathian mountain range and the Prut River in modern Romania. For a map showing the principality of Moldavia in 1350, see **Romania** (History).

Ottoman and Russian rule. The Ottoman Empire, based in present-day Turkey, gained control of the principality of Moldavia by the early 1500's. The Ottomans ruled the region until 1812, when Russia took control of Bessarabia. The Treaty of Paris that ended the Crimean War in 1856 gave southern Bessarabia to the principality of Moldavia, following Russia's defeat in that war. In 1859, the principality of Moldavia and the principality of Walachia, now a region in present-day Romania, elected the same prince. In 1861, their union under the name Romania received international recognition. Russia regained southern Bessarabia in 1878.

Romanian and Soviet rule. After World War I (1914-1918), all of Bessarabia became part of Romania. The Soviet Union, which had been formed as a Communist state under Russia's leadership in 1922, refused to recognize Bessarabia's unification with Romania. In 1924, the Soviets established the Moldavian Autonomous Soviet Socialist Republic (A.S.S.R.) in the Trans-Dnestr region. In 1940, during World War II, the Soviet Union seized Bessarabia. The Soviets merged most of Bessarabia with part of the Moldavian A.S.S.R. to form the Moldavian Soviet Socialist Republic. Bessarabia became part of Romania again in 1941, but the Soviet Union regained it in 1944.

While Moldova was part of the Soviet Union, the Moldovans were forced to use the Cyrillic alphabet instead of the Roman alphabet in writing their language. The Cyrillic alphabet is used to write the Russian language. In 1989, however, the republic's parliament ordered a return to the Roman alphabet.

From 1940 until the late 1980's, the Soviet government forbade religious instruction in Moldova and discouraged church attendance. But in 1990, the Soviet Union restored religious freedom.

Breakup of the Soviet Union. The Moldavian Supreme Soviet, as the legislature of the republic was then called, declared in 1990 that its laws took precedence over those of the Soviet Union. Moldavia also changed its name to Moldova.

In August 1991, conservative Communist officials failed in an attempt to overthrow Soviet President Mikhail S. Gorbachev. During the upheaval that followed, Moldova and several other republics declared their independence. In December, Moldova joined other republics in a loose association called the Commonwealth of Independent States. The Soviet Union was formally dissolved on December 25.

The leaders of independent Moldova restored many of the ties to Romania. They reintroduced Romanian history as a basic subject in the schools and sent thousands of Moldovans to study in Romanian schools. They also adopted the Romanian national anthem.

Threats to Moldovan unity. In 1990—before Moldova became independent—both the Gagauz people in southern Moldova and Russians and Ukrainians in the Trans-Dnestr region in eastern Moldova announced that they were forming independent states. These groups opposed proposals by some Moldovans to reunify Moldova with Romania. In March 1992, fighting broke out in the Trans-Dnestr region between ethnic Moldovans and separatists. In July, a peacekeeping force entered the region, and fighting ceased.

In February 1994, Moldova held its first parliamentary elections since declaring independence from the Soviet Union. The Agrarian Democratic Party, which opposes reunification of Moldova and Romania, won a majority of seats. The new government continued negotiations for a permanent settlement in Trans-Dnestr. In a nonbinding referendum on reunification held in 1994, most voters supported continued separation from Romania. A new constitution, which became effective in 1994, made Trans-Dnestr an *autonomous* (self-governing) territory.

In parliamentary elections in 1998, Communists won more seats than any other party. But several non-Communist parties joined together in a coalition to form the new government. In elections in 2001, the Communists gained control of parliament. Vladimir Tismaneanu

Mole is a small, thick-bodied mammal that lives underground. The mole is a fast, tireless digger. It has a narrow, pointed nose, a wedge-shaped head, and large forelegs. Its front paws, which turn outward, have long, broad nails. The forelegs work like shovels, scooping out the earth. The mole's hind legs are short and powerful. The animal is almost blind, with tiny eyes that are shaded by overhanging fur or skin. A mole does not have external ears, but it hears well.

A mole's home can be recognized by a cone-shaped mound of earth above it. This mound is much larger than the slightly raised roofs of the tunnels the animal makes when digging for food. Moles eat primarily worms and insects. Their diggings frequently spoil gardens and fields. Farmers set traps in the animals' tunnels.

Mole fur has been used in making coats and jackets. Furriers prefer bluish-gray mole fur, but they also use black, brownish-black, and paler shades. Moleskin is lightweight, warm, soft, and thick. But it does not wear well and has lost popularity through the years.

The eastern mole is found from Massachusetts and Florida to central Texas. It is 5 to 8 inches (13 to 20 centimeters) long, including a tail that measures about 1 inch (2.5 centimeters) in length. It weighs from $1\frac{1}{2}$ to 5 ounces (43 to 140 grams) and eats nearly its own weight in food every day. The eastern mole lives almost its entire life underground. It tunnels near the surface when searching for food. Most eastern moles live in nests about 1 foot (30 centimeters) underground.

Charles E. Mohr, Photo Researchers

A mole searches for earthworms and other food by digging tunnels with its sharp claws and powerful legs. It is nearly blind, but it does not need keen vision in its underground tunnels.

The star-nosed mole has a fringe of fleshy *tentacles* (feelers) around its nose. It has dark, blackish-brown fur on its upper parts, shading to a paler color underneath. The animal's long, hairy tail thickens at the base. The star-nosed mole lives in southeastern Canada and in the eastern United States as far south as Georgia. It likes to live near water and usually builds its home in the damp, muddy soil of a swamp or along the shore of a brook or pond. The star-nosed mole is an expert swimmer. In the winter, it burrows deep into the soil to avoid frost. See Mammal (illustration: The star-nosed mole).

The European mole builds a home that has many underground chambers. There is one central chamber that is connected to other smaller, round rooms. Passageways extend from these rooms in all directions. One passage, called the *bolt run,* serves as an exit in case of danger. The other passages lead to feeding grounds. In the central chamber is a nest. Three or four baby moles are born in early spring. The European mole is about the same size as the eastern mole.

Moles also live in parts of Asia. The largest species is the *Russian desman,* which is about 14 inches (36 centimeters) long, including the tail. It lives in southeastern Europe and central western Asia. The smallest species are the shrew moles and long-tailed moles of Asia and the Pacific Coast of North America. They are about 5 inches (13 centimeters) long, including their tails.

Hugh H. Genoways

Scientific classification. Moles belong to the mole family, Talpidae. The scientific name for the eastern mole is *Scalopus aquaticus.* The star-nosed mole is *Condylura cristata.* The European mole is *Talpa europaea.* The Russian desman is *Desmana moschata.*

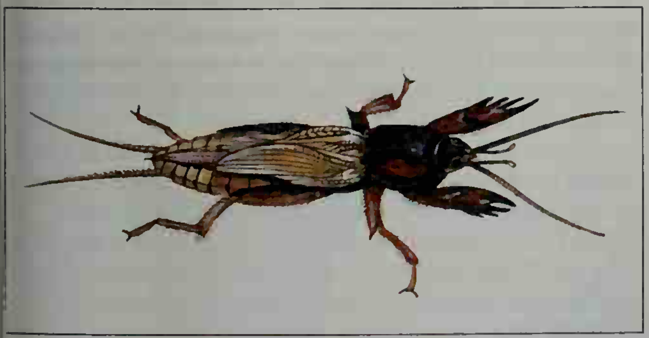
Mole is a unit used to measure the amount of a substance. One mole of any substance contains about 602,213,670,000,000,000,000,000 (602.214 billion trillion) of the *elementary entities* that make up the sub-

stance. These entities can be molecules, atoms, ions, electrons or other subatomic particles, or groups of particles. The large number is called the *Avogadro constant,* in honor of Italian physicist Amedeo Avogadro.

The mole is a base unit in the metric system of measurement. The symbol for the mole is *mol.* The mass in grams of 1 mole of a substance is the same as the number of *atomic mass units* (amu's) in one elementary entity of that substance. One amu is $\frac{1}{12}$ the mass of one atom of carbon-12. Carbon-12 is the *isotope* (form) of carbon whose atomic nucleus contains 6 protons and 6 neutrons (see **Isotope**). Thus, one atom—the elementary entity—of carbon-12 has a mass of 12 amu's, and 1 mole of carbon-12 has a mass of 12 grams. Peter A. Rock

Mole is a colored growth on the skin. It consists of cells that contain *melanin,* a dark pigment. Moles may be present at birth and are often called *birthmarks.* But most first appear during childhood or adolescence.

Moles may occur on any part of the body. They vary in size and may be flat or raised. They range from light brown to bluish-black. Most moles are small and do not change in appearance. Some have long, dark hairs.



Moles are extremely common—on the average, adults have about 40. The tendency to have many moles runs in families. Most moles are hardly noticed, but conspicuous moles may be considered unattractive by some people. Such moles can be removed by surgery.

The great majority of moles are harmless. In rare cases, however, a mole can develop into a cancerous tumor called a *melanoma.* A melanoma may start as a mole that changes color, itches, becomes sore, enlarges, grows crusty, or bleeds. Melanomas may destroy surrounding healthy tissue and may spread cancer to other parts of the body. Most of these tumors are curable if they are diagnosed and treated early. Therefore, any change in a mole should be reported to a physician immediately. Yelva Liptzin Lynfield

See also **Skin** (Tumors); **Birthmark**.

Mole cricket is a type of large insect that burrows in the ground like a mole. Its short front legs, like the mole's legs, are specially suited for burrowing. Most mole crickets also have wings and can fly. Mole crickets live in tropical and temperate regions. They live underground in burrows and also may be found in damp basements. Mole crickets eat insect larvae, earthworms, and root and tuber crops, including potatoes.

The most common species of mole cricket in North America is the *northern mole cricket.* It measures about $1\frac{1}{2}$ inches (4 centimeters) long and is velvety brown in color. The *changa,* a mole cricket of Puerto Rico, is the worst insect pest of the sugar crop.

WORLD BOOK illustration by John F. Eggert

A mole cricket burrows in the ground like a mole. This illustration shows a northern mole cricket.

Scientific classification. Mole crickets make up the mole cricket family, Gryllotalpidae. The scientific name for the northern mole cricket is *Neocurtilla hexadactyla.* The changa is *Scapteriscus vicinus.* Betty Lane Faber

Mole-rat is a type of small rodent. Mole-rats live in Africa and around the Mediterranean. They spend their entire lives underground. One of the most interesting species is the *naked mole-rat,* which lives in the hot, dry areas of Kenya, Ethiopia, and Somalia. Naked mole-rats live in organized communities. They are the only known mammals whose social behavior resembles that of such insects as bees, ants, and termites.

Naked mole-rats are about $3\frac{1}{3}$ inches (8.5 centimeters) long and weigh 1 to 2 ounces (28 to 57 grams). These animals appear hairless but actually have thinly scattered hair on their bodies. They are nearly blind, but they can feel objects with their whiskers and their body hair. They use their long front teeth to dig tunnels. Their body temperature varies with the temperature of their surroundings. Naked mole-rats communicate by means of complex vocalizations. They eat the underground parts of plants, such as roots and bulbs.

WORLD BOOK illustration by John F. Eggert

A naked mole-rat has wrinkled skin and scattered hair.

Each colony of naked mole-rats consists of 75 to 80 individuals. Within a colony, only one female has *pups* (young). Other females that attempt to reproduce are attacked. The breeding female has one to three mates and can produce more than 100 offspring each year. The other colony members help the breeders by carrying out specific activities. Smaller members find and transport food, clear tunnels, and build nests. Larger members excavate tunnels and protect the colony from enemies, such as poisonous snakes.

Scientific classification. Mole-rats belong to the families Bathyergidae and Spalacidae. The scientific name for the naked mole-rat is *Heterocephalus glaber.* Paul W. Sherman

Molecular biology is the study of those molecules that direct molecular processes in cells. For example, genetic information is stored in large molecules in the cells of organisms. The way in which these molecules convert their information into chemical reactions gives an organism its particular characteristics and is essential for its life. Molecular biology has provided a greater understanding of "what life is" and "how life works." Scientists use their knowledge of molecular biology in genetic engineering and other forms of biotechnology.

The beginning of molecular biology. The term *molecular biology* was first defined in 1938 by the Ameri-

can mathematician Warren Weaver as "those borderline areas in which physics and chemistry merge with biology." At that time, many physicists and chemists were investigating the biochemical processes that occur in living cells. Some studied the basic chemical "building blocks" of living cells, which include amino acids, lipids, and simple carbohydrates. Other scientists studied molecules thousands and even billions of times larger than the basic building blocks. These molecules are known as *macromolecules.* There are two chief kinds of macromolecules—nucleic acids and proteins.

The nucleic acid *DNA* (deoxyribonucleic acid) is the chief macromolecule in *chromosomes,* the cell structures that control heredity. In 1953, biologists James D. Watson of the United States and Francis H. C. Crick of the United Kingdom proposed a model for the structure of DNA. They correctly suggested that a molecule of DNA looks like a twisted ladder, or *double helix.* The rungs of the ladder consist of pairs of compounds called *bases.* Before a cell divides, the DNA ladder breaks lengthwise, separating the pairs of bases. The bases in each half ladder then attach to free bases, forming base pairs that are identical to the original ones (see **Cell** [DNA—the wondrous molecule]). This discovery indicated how information stored in DNA molecules could be transmitted, both to the new cells formed by cell division and to other parts of the cell, for the manufacture of proteins.

In the 1950's, molecular biologists formulated two important biological concepts—(1) the central dogma and (2) the genetic code. The central dogma states that DNA's instructions for making proteins are transmitted from DNA through *RNA* (ribonucleic acid). The genetic code refers to the sequences of bases in DNA and RNA molecules that determine the biological function of these macromolecules. For example, in a DNA molecule, a sequence of bases that provides instructions for making a specific protein is called a *gene.* A single molecule of DNA may contain thousands of genes. See **Cell** (RNA—the master copy; The genetic code).

Molecular biology today focuses primarily on determining why only some genes are expressed in certain cells of plants and animals. In these complex organisms, different kinds of cells have specific functions that are dependent on the regulated expression of specific genes. Beginning in the 1980's, research in this area contributed to the discovery of genes that can lead to cancer. Scientists hope that such knowledge may reveal new ways of treating the disease.

Scientists are now determining vast amounts of DNA sequences in the chromosomes of plants and animals. As a result of this work, a new area of molecular biology called *bioinformatics* is evolving. Bioinformatics uses computer technology to rapidly analyze the gene patterns in any tissue from any species. This technology enables scientists to study the gene patterns in diseased organs. Such studies could lead to the prevention and cure of many diseases. Perry B. Hackett, Jr.

Molecule is one of the basic units of matter. It is the smallest particle into which a substance can be divided and still have the chemical identity of the original substance. If the substance were divided further, only molecular fragments or atoms of chemical elements would remain. For example, a drop of water contains billions of water molecules. If one of those water molecules were separated from the rest, it would still behave as water. But if that water molecule were divided, only atoms of the elements hydrogen and oxygen would remain.

Individual molecules. Molecules are made up of atoms held together in certain arrangements. Scientists use chemical formulas to show the composition of molecules. For example, a water molecule consists of two hydrogen atoms and one oxygen atom, and it has the formula H_2O. A molecule's size and shape depends on the size and number of its atoms. A molecule that consists of two atoms, such as nitric oxide (NO), is called a *diatomic* molecule. A molecule made up of three atoms, such as water, is called a *triatomic* molecule. A large molecule, such as DNA, can contain millions of atoms.

Atoms link together in molecules through strong attractive forces called *bonds* (see **Bond** [chemical]). The shape of a molecule depends upon two factors: (1) The atoms tend to take up positions relative to one another such that the bonds formed are the strongest of all the bonds that this particular group of atoms could form. (2) Atoms that are not bonded to each other tend to move far apart. For example, an ammonia molecule has the shape of a *tetrahedron* (a pyramidlike figure with four faces). It consists of three hydrogen atoms attached to a nitrogen atom. Normal butane molecules have 4 carbon atoms arranged in a zigzag chain with 10 hydrogen atoms attached. Large protein molecules can form long spiral chains.

The mass of a molecule is indicated by its *molecular mass.* Molecular mass can be found by adding the *atomic masses* of all the atoms in a molecule. The molecular mass of carbon dioxide (CO_2) can be found by adding the atomic mass of carbon, which is 12, and the masses of the 2 oxygen atoms, which are about 16 each. Carbon dioxide has a molecular mass of about 44. A molecule's mass can also be measured with an instrument called a *mass spectrometer.*

Polar molecules and ionic substances. Each atom in a molecule consists of a positively-charged nucleus surrounded by a cloud of negatively-charged electrons. In a *neutral* molecule, the positive and negative charges are evenly balanced throughout the molecule. In *polar* molecules, the charges are not evenly balanced. In a polar molecule, more positive charge collects at one location in the molecule and more negative charge collects at a different location. Some molecules are magnetic because of the way the electrons are unevenly distributed within the molecule.

Almost all gases, most common liquids, and many solids are made up of neutral or polar molecules. But some substances are made up of units called *ions* (atoms or groups of atoms with a positive or a negative charge). These substances are called *ionic substances.*

Salts are examples of ionic substances. For example, sodium chloride, common table salt, consists of positive sodium ions and negative chloride ions. Electric forces among the ions hold them together in a regular frame-

work. Metals are also different from molecular substances. In addition to positive ions, metals consist of a large number of electrons that move about freely throughout the metal.

Molecules and matter. Molecules are held together in a group by electrical forces called *van der Waals forces.* These forces are usually weaker than those that hold a molecule itself together. The force between molecules depends on how far apart they are. When two molecules are widely separated, they attract each other. When they come very close together, they repel each other.

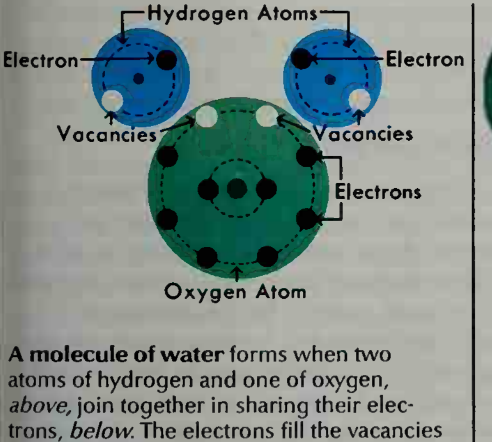
In a solid, the molecules are so arranged that the forces which attract and repel are balanced. The molecules vibrate about these positions of balance, but they do not have enough energy to move to different parts of the solid. As the temperature of a solid is raised, the molecules vibrate more strongly. When the van der Waals forces can no longer hold the molecules in place, the solid melts.

In a liquid, the molecules move about easily, but they still have some attractive force on one another. These forces are strong enough to keep the liquid together. Certain organic compounds called *liquid crystals* have properties of both liquids and solids. Within a particular temperature range, such a compound flows like a liquid, but has a more ordered molecular arrangement. Its molecules line up side by side and form tiny groups or clusters that slide past one another in certain directions. See **Liquid crystal.**

In a gas, the molecules move about so fast that the attractive forces have little effect on them. When two molecules in a gas collide, the repelling force sends them apart again. Therefore, gas molecules fill a container completely, because they move freely through all the space available.

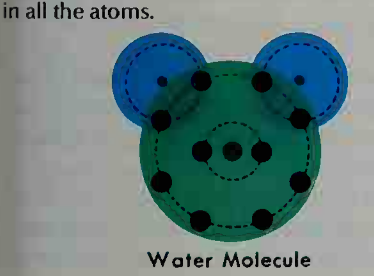
Most substances can be changed into solids, liquids, or gases by either raising or lowering their temperatures. The temperature at which these changes occur—and also other characteristics of a substance—depends on the size, shape, and mass of the molecules and also on the strength of the van der Waals forces between them.

Under certain conditions, two molecules may collide with enough energy to react and form one or more new molecules. The process by which many small molecules combine chemically to produce a large molecule is called *polymerization.* Molecules can also break down into smaller molecules. Causes of molecular disintegration include ultraviolet light, fast-moving electrons, and nuclear radiation.

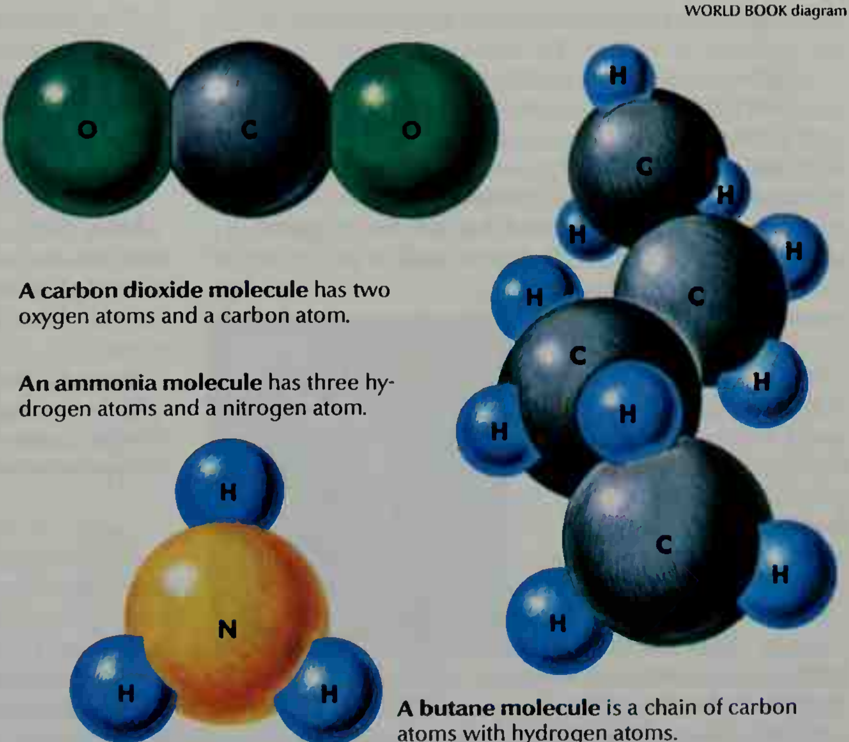


Studying molecules. Scientists can study some molecules directly with an *electron microscope.* This method provides a picture of a molecule, but the picture is often too blurred to see fine details. A *scanning tunneling microscope* produces an image of some individual atoms in a solid substance. Scientists also study molecules indirectly. For example, they study solids by *X-ray diffraction.* The way a solid deflects X rays tells them about the size, shape, and arrangement of its molecules. Scientists also use *neutron diffraction* and *electron diffraction* to study solids. They pass a beam of *neutrons* (uncharged particles) or electrons through a solid, and observe how the beam is affected. Electron diffraction can also be used to study gases.

Scientists also learn about molecules by studying the way they absorb or give off light. Each kind of molecule absorbs or gives off certain colors of light. This group of



Diagrams of some common molecules



Scientists study chemical compounds to learn how many atoms of each element are in the molecules and how these atoms are joined to each other. With this information, diagrams of molecules can be drawn with balls representing the individual atoms.

WORLD BOOK diagram

A molecule of water forms when two atoms of hydrogen and one of oxygen, *above,* join together in sharing their electrons, *below.* The electrons fill the vacancies in all the atoms.

A carbon dioxide molecule has two oxygen atoms and a carbon atom.

An ammonia molecule has three hydrogen atoms and a nitrogen atom.

A butane molecule is a chain of carbon atoms with hydrogen atoms.

Molière, *mohl YAIR* (1622-1673), was the stage name of Jean Baptiste Poquelin, the greatest French writer of comedy. Molière's plays emphasize one broad principle: the comic contrast between how people see themselves and how others see them.

Molière experimented with many drama forms. During his short career, he wrote farce, high comedy, satire, and comedy-ballets. He wrote equally well in verse and prose. Molière was also a fine actor and director.

Molière was baptized on Jan. 15, 1622, in Paris, and was the son of a prosperous upholsterer. He earned a law degree, but he never practiced law. In 1643, he and some of his friends founded the Illustre-Théâtre. From 1645 to 1647, the troupe toured France. In 1658, a performance attracted the attention of Louis XIV. The king gave Molière a permanent theater and asked him to write entertainments for the court.

Molière had no strong philosophy, but he had a knack for choosing controversial subjects that would attract public interest. His plays generally favor youth, love, and nature against age, selfishness, and efforts to imitate nobility. In 1662, *The School for Wives,* his first masterpiece in verse, satirized the narrow education given to girls of the middle class as well as an old man's claims to the love of his young female ward. As a result, he was attacked by extremist religious groups in France. *Tartuffe* (1664), was a satire on religious hypocrisy. It aroused such great church opposition that the play could not be performed for several years. Opposition from the church also forced *Don Juan,* or *The Stone Feast* (1665), to close after a short run. Molière then satirized universal human failings in *The Misanthrope* (1666), *The Miser* (1668), *The Learned Ladies* (1672), and other plays.

Molière in the Role of Caesar. Portrait by Nicolas Mignard, Comédie Française, Paris (National Photographic Service, Versailles)

Molière

Late in his career, Molière wrote a series of comedy-ballets in which the dramatic script was accompanied by interludes of song and dance, somewhat like today's musical comedies. These works include *George Dandin* (1668), *The Would-Be Gentleman* (1670), and *The Imaginary Invalid* (1673). Carol L. Sherman

Mollusk, *MAHL uhsk,* is any of a large group of soft-bodied animals that have no bones. Snails, slugs, clams, mussels, oysters, squids, octopuses, and scallops are mollusks. Most mollusks have a hard outer shell that protects their soft body. The shell is made of calcium carbonate, a chalky material. Some mollusks, such as cuttlefish and squids, possess no outer shell. A special inner shell supports their bodies. This shell is called a *cuttlebone* in cuttlefish, and a *pen* in squids. Other mollusks, including octopuses and certain slugs, have no shell at all. For more information on mollusk shells and how they are formed, see **Shell.**

All mollusks have a skinlike organ called the *mantle.* Sometimes the mantle has sensitive projections called *tentacles* that help the animal sense its surroundings. In mollusks with an outer shell, the mantle lies between it and the soft body. In mollusks with no outside shell, the mantle forms a tough cover around the internal organs. Most land mollusks also use the mantle to breathe, but aquatic mollusks generally have gills for this purpose.

Mollusks live in most parts of the world. Some live in bodies of water, such as oceans, rivers, and lakes. Others live on wooded mountain slopes. Still others live in deserts. Wherever mollusks live, they must keep their bodies moist to stay alive. Most land mollusks live in damp places, such as under leaves or rocks, or in soil.

The importance of mollusks

Many kinds of mollusks, including clams, oysters, scallops, and squid, are used as food. Mollusks are made into many products, including buttons and calcium pills. Overharvesting and pollution have endangered some kinds of mollusks, such as freshwater mussels.

Some mollusks are harmful or bothersome to people. Certain tropical snails carry *flukes,* worms that cause the deadly sickness *schistosomiasis.* Other mollusks may cause severe wounds, or damage property and crops.

Kinds of mollusks

Mollusks are the largest group of water animals. There are about 100,000 different kinds of living mollusks, plus 100,000 known fossils. Each year, scientists find about 1,000 new species.

The mollusks make up a *phylum* (major division) of the animal kingdom. The scientific name of the phylum is *Mollusca,* a Latin word meaning *soft-bodied.* To learn

where the phylum fits into the animal kingdom, see Animal (table: *A classification of the animal kingdom*).

There are seven *classes* (large groups) of mollusks. They are (1) gastropods *(GAS truh pahdz)*, also known by the scientific name Gastropoda *(gah STRAHP uh duh)*, (2) bivalves or Bivalvia *(by VAL vee uh)*, (3) octopuses and squids, also called cephalopods *(SEHF uh luh pahdz)* or Cephalopoda *(sehf uh LAHP uh duh)*, (4) tooth shells, also called tusk shells, scaphopods *(SKAF uh pahdz)*, or Scaphopoda *(skah FAHP uh duh)*, (5) chitons *(KY tuhnz)* or Polyplacophora *(pah lee pluh KAHF uh ruh)*, (6) Monoplacophora *(mahn oh pluh KAHF uh ruh)*, and (7) Aplacophora *(ay plah KAHF uh ruh or ap luh KAHF uh ruh)*.

Gastropods (Gastropoda), or snails, are the largest class of mollusks. They are also called *univalves*, because their shell is made of one *valve* or plate. They include limpets, slugs, and whelks.

The name *Gastropoda* is Greek and means *stomach foot*. Gastropods seem to crawl on their bellies. In reality, they use a large muscular organ called a *foot* that ripples and helps them to move forward. Many snails have two pairs of tentacles on their heads. One pair helps the animal to feel its way about. Each tentacle of the second pair may have an eye at its tip or base.

Gastropods eat plants, meat, or both. They have a *radula*, a hard ribbon of small teeth that works like a file to tear food. Plant eaters possess a broad radula with thousands of small teeth. Meat eaters have fewer teeth, but these are strong and sharp.

For protection, most snails can pull back into their shell. Many have a small, lidlike door called an *operculum* on the back of their foot. When they draw into their shell, the operculum closes over the shell opening.

Bivalves (Bivalvia) form the second largest class of mollusks and include clams, oysters, mussels, scallops, and shipworms. All bivalves have a shell made up of two valves. A flexible tissue connects the valves, and toothlike hinges keep them aligned. When the animals are feeding or breathing, the valves separate slightly. When disturbed, bivalves use one or two strong muscles called *adductor muscles* to shut the valves tight. Scallops use a single large adductor muscle to quickly open and close their shell. This muscle is the part of the scallop that we eat. Scallops propel themselves through the water by rapidly opening and closing their shell.

Bivalves use a strong, muscular foot to travel. Many bivalves employ their foot to poke through sand and anchor themselves. Some use their shells to burrow into wood or rock. The common ocean mussel attaches to hard surfaces with its *byssal threads*, strong protein strands made by a gland in its foot.

Bivalves have no head. They get oxygen and food through a muscular *siphon* (tube) at the back of their body. A second siphon releases waste. Bivalves feed on plankton by trapping it on their gills, then moving it to their mouths. Some bivalves have no gut and feed on chemicals found in ocean waters. The animals breathe by using gills to take oxygen from the water and release carbon dioxide back into the water.

Octopuses and squids (Cephalopoda) are the most active, intelligent mollusks. The word Cephalopoda comes from Greek words meaning *head* and *foot*. Cephalopods have large, dome-shaped bodies that look like heads. The argonaut, cuttlefish, and nautilus belong to this group. All its members live in the ocean.

Octopuses have eight arms. Squids and cuttlefish have eight arms plus two tentacles that can be extended. The arms and tentacles help capture prey, usually crabs, shrimp, fish, clams, or snails. Beneath the body is a mouth with strong, sharp, beaklike jaws that crush and tear prey. Some cephalopods have a poisonous bite.

Squids have a weak internal shell, and octopuses have no shell. The nautilus has a beautiful outer shell with small gas chambers, which enable it to hover in water.

Tooth shells (Scaphopoda) have slender, curving, tusklike shells. The word *Scaphopoda* comes from the Greek for *boat* and *foot.* The pointed foot of these mollusks resembles a small boat. Tooth shells live in the ocean and burrow in sand or mud. The top of their shell sticks up into the water. They have no head or eyes. Their tentacles sweep small creatures into their mouth.

Chitons (Polyplacophora) have flat, oval bodies covered by eight shell plates. A tough mantle, called a girdle, holds the plates in place. The name *Polyplacophora* comes from Greek words meaning *many, plate,* and *bearer.* Chitons have a large, flat, muscular foot. They can use the foot to travel, but usually cling to ocean rocks. If pried from a rock, a chiton curls into a ball. Chitons have a small head and mouth, but no eyes and no tentacles. Their long radula has many small teeth, which they use to scrape food, usually algae, from rocks.

Monoplacophora live deep in the ocean. Most are found as fossils. The name *Monoplacophora* comes from Greek words meaning *single, plate,* and *bearer.* The single plate of a monoplacophoran is nearly flat. Monoplacophora have several pairs of gills, six or more pairs of kidneys, and many nerve centers. They also have a radula. Little is known about their habits.

Aplacophora are wormlike ocean mollusks. Most grow less than $\frac{1}{4}$ inch (0.64 centimeter) long. The name *Aplacophora* comes from Greek words meaning *no, plate,* and *bearer.* Aplacophorans do not have a shell plate. The outer layer of their bodies is covered with small spines. These mollusks possess a small radula. Scientists have rarely had live aplacophorans to study.

Molly is the name of a group of small, colorful fish popular in home aquariums. Mollies are *live-bearers*—that is, they give birth to live, fully formed young. Most other fishes reproduce by laying eggs. Mollies are closely related to the guppy, another type of live-bearer (see **Guppy**).

Mollies are native to freshwater streams of South America, Central America, and the southern United States. They sometimes enter pools and lagoons that have seawater mixed with fresh water. Adult mollies range in size from 3 to 6 inches (8 to 16 centimeters). Most species are naturally bluish or silvery-olive with various spots and bars. Male mollies are usually more colorful than females and have larger fins.

Favorite aquarium species include the *Amazon molly,* the *sailfin molly,* and the *shortfin molly.* Selective breeding has resulted in many colorful varieties of mollies that would not normally occur in nature. John E. McCosker

Scientific classification. Mollies belong to the family of live-bearing fishes, Poeciliidae. They are in the genus *Poecilia.*

Molly Maguires was the popular name for members of a secret society of immigrant Irish coal miners in the United States. Their name was based on a legendary Irish heroine who supposedly led a revolt of peasant farmers against rent collectors in the 1600's. The members of the secret society occasionally dressed in women's clothing to surprise their enemies. The society took part in violent labor conflicts between mine owners and workers in Pennsylvania during the 1870's. The group was accused of using murder and terror against its enemies. Ten members convicted of murder were executed on June 21, 1877. David Brody

Molnár, *MOHL nahr,* **Ferenc,** *FEH rehnts* (1878-1952), became the most widely known Hungarian dramatist of his time. He specialized in writing light romantic comedies with witty dialogue. In *The Guardsman* (1910), a jealous husband pretends to be his own rival. *The Glass Slipper* (1924) presents a comic version of the Cinderella story.

Liliom (1909), a more serious play about an amusement park barker, later served as the basis for the Rodgers and Hammerstein musical *Carousel.* Molnár's other popular comedies include *The Devil* (1907), *The Swan* (1920), and *The Play's the Thing* (1926).

Molnár was born in Budapest. He studied law and worked as a journalist before turning to drama. In addition to his plays, he wrote several novels and many humorous character sketches and essays. In 1940, Molnár moved to the United States and later became an American citizen. Gerald M. Berkowitz

Molokai. See **Hawaii** (The islands).

Molotov, *MAHL uh TAWF,* **Vyacheslav Mikhailovich,** *vyah cheh SLAHF mih KHY lah vihch* (1890-1986), became widely known during two terms as foreign minister of the Soviet Union. He was demoted in 1957 for his opposition to Nikita S. Khrushchev, first secretary of the Soviet Communist Party. He was expelled from the Communist Party's Presidium and sent into virtual exile as ambassador to Outer Mongolia. In 1960, he became the Soviet delegate to the International Atomic Energy Agency. The Soviet Communist Party attacked him in 1961, and he returned to Moscow. In 1962, Molotov was expelled from the party, but he was reinstated in 1984.

From 1939 to 1949 and from 1953 to 1956, Molotov served as commissar (later called minister) of foreign affairs. He helped create the Soviet Union's policy of hostility to the West, particularly to the United States. He attacked the North Atlantic Treaty Organization (NATO) as an agency that would lead to another war. He proposed a collective security treaty for European countries that would exclude the United States.

Molotov joined the Bolshevik Party at the age of 16 (see **Bolsheviks**). Beginning in 1906, he engaged in various revolutionary activities. He was arrested and exiled twice, but returned to help plan the Bolshevik revolution. After the Bolshevik (now Communist) Party seized power in Russia in 1917, he received several important political promotions. He served as premier of the Soviet Union from 1930 to 1941.

Molotov was born in the Kirov region of European Russia. His family name was Skriabin, but he changed it to Molotov, which derives from *molot,* the Russian word for *hammer.* Melvin Croan

Molting is the process by which an animal sheds worn hair, skin, scales, feathers, or fur and grows a new body covering. Molting often occurs at a definite time each year known as the animal's *molting season.*

The process of molting varies with different animals. Some animals have a hard outer covering, called an *ex-*

E. R. Degginger

A molting snake rubs its nose against a rough surface, such as a rock or tree trunk, until its skin breaks away. Then it slides out of the old skin, leaving it turned inside out. The process takes only a few minutes. This snake is an albino corn snake.

oskeleton, that is too firm to expand as the animal grows. These animals, including crabs, lobsters, and insects, must periodically shed their outer shell and grow a new one. The old exoskeleton becomes detached by fluid that appears beneath it. A new, soft exoskeleton grows in folds beneath the old, detached covering. The animal presses against the old exoskeleton, causing it to split, and wriggles out. The new exoskeleton then unfolds and hardens. Caterpillars of several kinds of butterflies shed their skin as many as five times as they grow. Adult insects do not molt. Lobsters, crabs, and similar animals molt irregularly throughout life.

Many reptiles also molt throughout life. Snakes and lizards shed and replace their entire skin. Alligators and crocodiles shed and replace each of their scales individually. This pattern of molting is similar to that of birds.

Birds shed their feathers at least once a year and grow a new set. A complete molt typically takes four to six weeks and occurs in late summer. Large birds may require more than a year to molt completely, or they may molt almost continuously. Worn feathers are pushed out by new ones in a regular pattern. In most birds, a feather used for flying is shed only after the one next to it is partly regrown. Thus, the bird maintains its ability to fly. Ducks, geese, and swans shed all their flight feathers at once and are flightless during their molting season. In many birds, molting also plays an important part in courtship. Old, dull feathers are replaced by brightly colored ones that help attract a mate.

Many mammals shed their hair each spring. Some animals replace body parts during their molting season. For example, deer replace their antlers. The lemming, an animal similar to a guinea pig, and the ptarmigan, a grouselike bird, replace their claws. Edward H. Burtt, Jr.

Moltke, *MAWLT kuh,* **Helmuth Karl von** (1800-1891), was a Prussian military genius. He ranked next to Prince Otto von Bismarck as a builder of the German Empire.

Moltke was appointed to the Prussian general staff in 1832. He became chief of staff in 1858. As chief of staff, Moltke prepared the military plans for the wars with Denmark in 1864, with Austria in 1866, and with France in 1870. His campaigns always succeeded. Moltke's greatest triumph was the Prussian victory over France. His armies won decisively at Sedan on Sept. 2, 1870. Metz fell in October, and the Prussian armies entered Paris in triumph (see **Franco-Prussian War**).

Moltke was born in the duchy of Mecklenburg-Schwerin and grew up in the city of Lübeck. He graduated from the Royal Military Academy in Copenhagen. His nephew Helmuth von Moltke served as commander of the German Army in France at the beginning of World War I. Charles W. Ingrao

Moluccas. See **Indonesia** (The Moluccas); **Netherlands** (Diversity).

Molybdenum, *muh LIHB duh nuhm,* is a hard, silvery-white metallic element. Its high melting point, which is 2617 °C, makes it one of the strongest and most commonly used heat-resistant metals. When used in steel, it improves that metal's toughness and strength, especially at high temperatures. It also increases the heat and chemical resistance of certain nickel-based metals.

Molybdenum is widely used in aircraft and missile parts. Molybdenum compounds have many industrial uses, particularly as catalysts in the refining of petroleum. Molybdenum sulfide is used as a high temperature lubricant under conditions where most oils decompose.

Molybdenum is found in molybdenite and a number of other minerals. In the United States, concentrated deposits of molybdenite ore occur in Colorado. Some of this ore is being mined. Canada and Chile also produce molybdenite. There is a large deposit of molybdenite ore near Ketchikan, Alaska. It contains about 1.5 billion tons (1.4 billion metric tons) of ore, or about 13 percent of the known deposits in the world. Carl Wilhelm Scheele, a Swedish chemist, discovered molybdenum in 1778. The element has the chemical symbol Mo. Its atomic number is 42, and its atomic weight is 95.94. Molybdenum boils at 4612 °C. R. Craig Taylor

Mombasa, *mahm BAH suh* (pop. 442,369), is the second largest city of Kenya, after Nairobi. Mombasa is a busy seaport on the east coast of Africa (see **Kenya** [map]). It handles most of the international shipping of Kenya; and of Uganda, Rwanda, Burundi, and eastern Congo (Kinshasa), which lie inland. The city has an oil refinery, an international airport, and a modern section with government buildings and many resort hotels.

Persian and Arab traders settled at what is now Mombasa as early as the 700's. The city became an important port in the 1200's, when ivory, gold, timber, and slaves were shipped from Africa to other lands. Mombasa was controlled by Portugal for most of the period from 1528 until 1698, and by Oman from 1698 until 1887. The United Kingdom controlled the city from 1887 until 1963, when Kenya became independent. Stephen K. Commins

Moment magnitude is a number that indicates the strength of an earthquake. It is related to the energy released during the earthquake. A Japanese *seismologist* (scientist who studies earthquakes) named Hiroo Kanamori designed the moment magnitude scale of numbers in 1977. This scale is an improvement of the Richter magnitude scale, which American seismologist Charles F. Richter invented in 1935. In both scales, the stronger the earthquake is, the higher is the magnitude. The Richter and moment magnitudes are nearly identi-

cal for most earthquakes with a magnitude less than 7. However, moment magnitude measures the strongest earthquakes more accurately.

Scientists can determine moment magnitude in two ways. In the first method, they measure the length and depth of the earthquake *fault* and the movement of rock at the fault. A fault is a fracture in the earth's rocky outer shell where sections of rock repeatedly slide past each other. In the second method, scientists use data from a *seismograph,* a device that records ground movements. Richter magnitude is based on seismographic data.

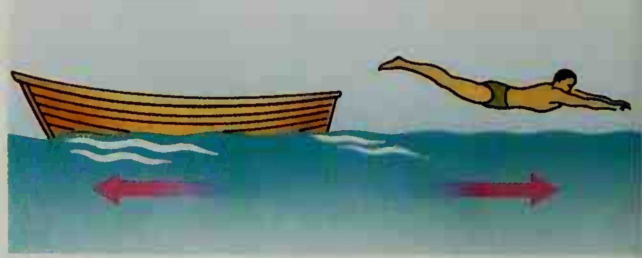
The main difference between the two scales lies in the *frequencies* of the movements that are recorded. Frequency is a measure of how often the ground moves back and forth in one second. During an earthquake, the ground shakes at several frequencies at the same time. The movements travel together through the ground, just as radio broadcast waves of different frequencies travel through the air. Like a radio receiver, older seismographs were "tuned" to a certain range of frequencies.

Richter magnitude depends on a single measurement—the greatest distance the ground moves in a certain band of frequencies recorded by one type of older seismograph. This band does not include the lowest frequencies at which the ground moves. But as earthquakes become larger, their movement grows more at low frequencies. Thus, the Richter scale may underestimate the strength of an extremely large earthquake.

In contrast, moment magnitude depends on the greatest distance the ground moves at the lowest recorded frequencies. Seismographs can record many frequencies at once, so moment magnitude can be measured accurately for both big and small earthquakes.

The biggest earthquake ever recorded occurred in the Pacific Ocean near Chile in 1960. In this quake, a fault 500 miles (800 kilometers) long moved 70 feet (21 meters). The quake's moment magnitude was 9.5, but its Richter magnitude was only 8.3. Martha Kane Savage

See also **Earthquake; Richter magnitude.**



Momentum is a measure of the motion of an object. The momentum of a moving object equals its *mass* (quantity of matter) multiplied by its *velocity* (speed in a given direction).

Consider, for example, an automobile that weighs 1,000 kilograms (2,200 pounds), which means it has a mass of 1,000 kilograms. Suppose the car is moving north at 25 meters per second (about 55 miles per hour). The automobile's momentum will be 25,000 kilogram meters per second toward the north. Now, consider a truck that weighs 5,000 kilograms (11,000 pounds). To have the same momentum as the car, the truck must travel northward at only 5 meters per second (about 11 miles per hour).

The English scientist and mathematician Isaac Newton discovered the laws of momentum. His findings appeared in *Philosophiae Naturalis Principia Mathematica (Mathematical Principles of Natural Philosophy),* a book published in 1687.

Newton's laws include the *law of conservation of momentum.* According to this law, the momentum of an object will change only if a *net force* acts on it. A net force is a force that is not balanced by an opposing force.

In our example, several forces will tend to slow the automobile. These forces include the resistance of the surrounding air to the motion of the car and the friction force of the tires against the road. But the force created by the car's engine will tend to make the vehicle go faster. If this force balances the forces tending to slow the car, the vehicle will travel at a constant speed. Our example does not include any force that would tend to change the automobile's direction. Therefore, the vehicle's velocity and momentum will also remain constant.

WORLD BOOK diagram by Sarah Woodward

Total momentum stays the same during a dive from a boat. The boat and diver move in opposite directions. The boat's momentum is opposite and equal to the diver's momentum.

The law of conservation of momentum also applies to *systems* (interacting sets) of objects. Consider a system made up of two equally massive bumper cars. Suppose each car is going 4.5 meters per second (10 miles per hour), and the cars are moving directly toward each other. The two cars will have the same amount of momentum. However, the momentum of one will point in the direction opposite that of the other. The total momentum of the two cars will therefore be zero.

Suppose the cars collide head-on and bounce off each other at 4.0 meters per second (9 miles per hour). The collision will change both cars' momentum. But, because no force from outside the system has acted on the cars, their total momentum remains zero. Michael Dine

Mona Lisa. See **Leonardo da Vinci** (Return to Florence; Paintings; picture).

Monaco, *MAHN uh koh,* is one of the smallest countries in the world. It has an area of less than 1 square mile (2 square kilometers). Monaco lies on the French Riviera, which borders the Mediterranean Sea. France borders it on the other three sides.

Monaco is a popular tourist resort, with many luxury hotels, clubs, flower gardens, and places of entertainment. One of its chief attractions is the famous Monte Carlo gambling casino. Monaco is also known for such automobile sports events as the Monte Carlo Rally and the Monaco Grand Prix.

The towns of Monaco and Monte Carlo sit on cliffs overlooking the Mediterranean. Monaco is the capital. Prince Rainier III rules from a castle, part of which was built in the 1200's. Monaco's official language is French. The citizens of Monaco are called *Monégasques.*

Government. Monaco is a *principality* (ruled by a prince). The prince represents Monaco in international affairs, including the signing of treaties. Under the terms of a treaty that was signed with France in 1918, if the royal family of Monaco produces no male heirs, the principality will come under French rule.

A minister of state, under the authority of the prince,

heads the government. The minister is a French civil servant chosen by the prince. Three councilors who are responsible for finance, police and internal affairs, and public works assist the minister of state. The 18-member National Council shares the legislative powers with the prince. Citizens of Monaco elect National Council members to five-year terms. The council must approve changes in Monaco's Constitution.

People. Only about a seventh of the people who live in Monaco are citizens. Over half its residents are French, and most of the others are Americans, Belgians, British, and Italians. Most people in Monaco speak French. Native residents converse in a dialect called Monégasque, which is based on French and Italian.

Many wealthy people from other countries make Monaco their home because the principality has no income tax. But since 1963, most French people living in Monaco have had to pay income tax at French rates.

Facts in brief

Capital: Monaco.
Official language: French.
Area: 0.58 mi² (1.49 km²).
Population: *Estimated 2002 population*—35,000; density, 60,345 per mi² (23,490 persons per km²); distribution, 100 percent urban. *1990 census*—29,972.
Chief products: Chemicals, cosmetics, pharmaceuticals.
Flag: The flag has two horizontal stripes, red and white. See **Flag** (picture: Flags of Europe).
Money: *Basic unit*—euro. One hundred cents equal one euro. The French franc, Monaco's former currency, was taken out of circulation in 2002.

The state religion is Roman Catholicism. There is complete freedom of worship. Monaco's primary schools are run by the church. The principality also has a high school and a music academy.

The Monaco government awards the Rainier III prize for literature each year to a writer in the French language. Monaco's libraries include the Princess Caroline Library, which specializes in children's literature. Monaco also has a marine museum, a prehistoric times museum, a zoo, and botanical gardens. The marine museum has several rare exhibits, one of the world's leading aquariums, and a laboratory for research.

The Grand Theater of Monte Carlo presents performances by some of the world's greatest singers and ballet dancers. Leading musical conductors and soloists perform with Monaco's national orchestra.

Land. Monaco lies at the foot of Mount Agel, which lies mainly in France. In places, Monaco stretches only 200 yards (180 meters) inland from the Mediterranean.

Monaco has four sections—three towns and an industrial area. Monaco, the old town and former fortress, stands on a rocky point 200 feet (61 meters) high. It is dominated by the royal palace. Monte Carlo has the famous gambling casino, the opera house, hotels, shops and beaches. La Condamine, a port area, lies between the towns of Monaco and Monte Carlo. The industrial zone, called Fontvieille, lies west of the town of Monaco.

The country has a mild winter climate, with an average January temperature of 50 °F (10 °C). Summer temperatures rarely exceed 90 °F (32 °C). On the average, rain falls only 62 days a year.

Economy. Since 1980, industrial production has expanded greatly. Monaco's chief products include chemicals, cosmetics, pharmaceuticals, and plastics.

Tourism contributes much to the economy. Each year, more than 600,000 tourists from around the world visit the principality. A company called the Société des Bains de Mer, which is partly owned by the government, operates the casino and most of the hotels, clubs, beaches, and other places of entertainment. Monaco's colorful postage stamps are popular with collectors. Postage stamps are a significant source of income in Monaco.

E. Nagele, FPG

Monte Carlo is a tourist resort in Monaco. The town lies on the French Riviera coast of the Mediterranean Sea.

Many foreign companies have headquarters in Monaco because of the low tax rates. Monaco's banks and financial service companies cater to these businesses and to the country's many wealthy residents.

The principality of Monaco has a local bus service. The main highway on the coast passes through Monaco, carrying motorists who are traveling between France and Italy. A railroad connecting France and Italy also runs through Monaco. The principality transmits its own radio and television programs. Its television transmitter is located on top of Mount Agel, in French territory.

History. Monaco's museum contains many artifacts, including remains and tools, of early peoples in the area. Phoenicians from the eastern Mediterranean probably settled in Monaco in about 700 B.C. In Greek and Roman times, Monaco was an important trading center, and its harbor sheltered ships from many lands.

Ruling families from Genoa, in northern Italy, gained control of Monaco in the A.D. 1100's. They built the first fort there in 1215. The Grimaldi family began ruling Monaco in 1297. They lost control in 1301 but regained it in 1331. The family first allied itself with France. During the early 1500's to mid-1600's, the Grimaldi's turned to Spain for protection. Palace revolts and violence marked this period in Monaco's history. Prince Jean II was murdered by his brother Lucien in 1505. Lucien was later murdered by a relative. Prince Honoré I was drowned by some of his subjects during a revolt in 1604.

France seized control of Monaco in 1793, during the French Revolution. In 1814, the Congress of Vienna restored control to the Grimaldi family under the protection of Sardinia. France seized some of Monaco's territory in 1848, but the territory was returned in 1861.

The princes of Monaco ruled as absolute monarchs until 1911, when Prince Albert I approved a new constitution. Prince Albert was known as the *Scientist Prince.* He did important marine research and founded Monaco's famous Oceanographic Museum. Prince Louis II ruled from 1922 until 1949, except for the German occupation during World War II. His grandson Prince Rainier III succeeded him. In 1956, Rainier married American motion-picture star Grace Kelly, who took the title of Princess Grace. They had two daughters and a son. The son, Prince Albert, is heir apparent.

In 1959, Prince Rainier dissolved the National Council and appointed a National Assembly. In 1962, under pressure from France, he restored the National Council and granted Monaco a new constitution. The constitution provided votes for women and abolished the death penalty. In 1963, under pressure from France, Monaco taxed business profits for the first time.

In the late 1900's, Monaco expanded its size by reclaiming land from the sea. In 1982, Princess Grace died following an automobile accident near Monaco.

Monaco joined the United Nations in 1993. In 1997, the country celebrated 700 years of rule by the Grimaldi dynasty. Janet L. Polasky

Monarch butterfly. See **Butterfly** (picture).

Monarchy is a form of government in which one person who inherits, or is elected to, a throne is head of state for life. These persons, or monarchs, have different titles, including *king, emperor,* or *sultan,* in various governments. The old idea of monarchy maintained that the power of the monarch was absolute. It sometimes held that the monarch was responsible only to God. This doctrine became known as "the divine right of kings" (see **Divine right of kings**).

Revolutions destroyed much of the power of monarchs. In the 1640's, the English Parliament raised an army, defeated King Charles I, and condemned him to death. In 1688, the English people feared James II would restore the Roman Catholic faith, and forced him to give up his throne. The French Revolution of 1789 limited the power of Louis XVI, and in 1793 the revolutionists put him to death. As a result, *limited,* or *constitutional,* monarchy developed, in which the monarch's duties are largely ceremonial and symbolic. In modern constitutional monarchies, the executive power is usually exercised by a prime minister and Cabinet. Denmark, Japan, Norway, Sweden, and the United Kingdom are modern constitutional monarchies. Alexander J. Groth

Monastery. See **Monasticism; Monk; Cloister.**

Monasticism, *muh NAS tuh sihz uhm,* is a special form of religious community life. People who practice monasticism separate themselves from ordinary ways of living so they can follow the teachings of their religion as completely as possible. Men who adopt a monastic life are called monks and live in a monastery. Monastic women are called nuns and live in a convent.

Monasticism has an important part in several major religions. The word comes from the Greek word *monos,* meaning *alone.* The first Christian monastics were called *ones who live alone* because they lived by themselves in the desert. Later, groups of them gathered together and formed communities that followed a life of prayer and self-discipline. Today, the members of monastic communities also follow this kind of life.

Christian monasticism began in Egypt about A.D. 271, when Saint Anthony of Thebes went alone into the desert to lead a holy life. Others soon followed. In the

John Topham, The Image Works

Benedictine monks in a French abbey walk under a covered passage called a cloister. Such monks live away from the outside world, devoting themselves to prayer, study, and work.

early 300's, Saint Pachomius, another desert holy man, gathered some of these hermits into monasteries.

Monasticism became especially influential in Europe during the early Middle Ages. At that time, Europe had thousands of monasteries that were great centers of learning. After about 1200, however, Christian monasticism began to be replaced by orders of wandering friars. It has never regained its former influence. See **Middle Ages** (The Christian church).

Life in a Christian monastic community involves work, prayer, and meditation. A monastery or convent may be in a rural area or in a city. It may consist of a small, walled-in group of huts or a huge complex that houses hundreds of people. But it is designed to isolate its people from the world outside. Christian monasticism also includes an extremely important element called the *rule,* a set of guidelines by which members of a monastic group live. Its essential purpose is to set specific times each day for study, work, prayer, and other activities. Eastern Orthodox monastic groups base their rule on the teachings of Saint Basil of Caesarea, who lived in the 300's. The Rule of Saint Benedict of Nursia, written in the 500's, is the model for most Roman Catholic groups.

In addition to following a rule, Christian monks and nuns take three vows—*poverty, chastity,* and *obedience.* The vow of poverty requires a person not to own any private possessions. The vow of chastity obligates a monk or nun to have no sexual relations. The vow of obedience requires a person to always follow the decisions of the leader of the monastic community.

There are several Christian monastic orders. Each of these groups of monasteries or convents follows the same rule and shares a common leadership. There are also many nonmonastic orders. The members of these groups dedicate their lives to preaching and service, rather than to prayer and meditation.

Non-Christian monasticism. A number of non-Christian religions also have monastic communities. For example, monasticism in Buddhism began in the 500's B.C., about 800 years before Christian monasticism. Buddha, the founder of the religion, taught his followers to give up their family, work, and material things. Early Buddhist monks and nuns spent most of their time as wandering *mendicants* (holy beggars). Today, few Buddhist nuns are left, and most Buddhist monks live in monasteries. A highly detailed rule called the *Vinaya* guides everything they do. See **Buddhism**.

The monks and nuns of Jainism, an ancient religion of India, still live much as the first Buddhist monastics did. They are wandering mendicants who lead extremely strict lives and strive never to harm any living creature, not even an insect. See **Jainism**.

Hinduism has had religious hermits since ancient times. But they were never well organized until about A.D. 800, when a great teacher named Sankara founded an order with four monasteries. Since then, about 10 large orders and many small ones have developed.

The influence of monasticism today has declined almost everywhere. Perhaps the chief reason for this decline has been widespread *secularism* (doubt of the value of religion). Christian monastic groups have lost members who question the value of the traditional vows, especially the vow of chastity. In addition, Communist governments have persecuted Buddhist monastics in China, Tibet, and parts of Southeast Asia. Most Hindu monastic orders also have fewer members.

On the other hand, there has been renewed interest in monasticism among some religious groups. The Ramakrishna Mission, a modern Hindu order involved in social work, has attracted a large following in India and in other parts of the world. Tibetan Buddhist exiles have founded successful monasteries in the United States. The Lutheran and Dutch Reformed churches and several other Protestant groups have also started monastic communities. Monazite, *MAHN uh zyt,* is a heavy, yellow-brown mineral. It is a compound of phosphates (phosphorus and oxygen) of the rare-earth metals and thorium. Its chemical formula is (Th, Ce, La, Y)PO_4. Monazite is one of the chief sources of thorium, a nuclear fuel used in some nuclear reactors. Monazite is also an important source for the rare-earth elements and compounds, used widely in glass and metal manufacturing.

Monazite occurs in granite rocks and pegmatite veins. As these rocks weather and break up, the monazite settles in deposits in riverbeds and beach sand. Commercial supplies of monazite are taken from sand. The most important deposits occur in India and Brazil.

Rodney C. Ewing

Monck, George (1608-1670), was an English general and naval commander. His name is also spelled Monk. He helped restore King Charles II to the English throne in 1660.

Monck joined the army at the age of 17. He commanded Irish troops for the king in the English Civil War in the 1640's, which ended with the triumph of Parliament and the English political and military leader Oliver Cromwell (see **Cromwell, Oliver**). The parliamentary troops defeated Monck in 1644 and imprisoned him in the Tower of London for two years. Cromwell then offered to free him if he would serve in the army of the Commonwealth of England. Monck did so and was made a lieutenant general.

He served the Commonwealth as commander in chief of Scotland in 1651 and 1652 and from 1654 to 1659. He helped command the English Navy in 1652 and 1653, and he defeated the Dutch in several naval battles.

After Cromwell's death in 1658, Monck made possible the peaceful return of King Charles II. The Presbyterian members who had been driven out of Parliament in 1648 were brought back. Their presence in Parliament made certain a majority in favor of restoring Charles. Monck quietly shifted the armed forces throughout England to prevent any chance of an uprising.

Monck led Parliament in bringing back Charles II in 1660. Charles rewarded Monck by giving him a large

pension and by making him Duke of Albemarle, *privy councilor* (adviser to the king), and lord lieutenant of Devon and Middlesex (now part of London). Monck was born in the English county of Devon. Charles Carlton

See also **Restoration**.

Monck, *muhngk,* **Viscount** (1819-1894), was the first governor general of the Dominion of Canada. The Dominion was formed by a union of British North American colonies in 1867. Monck served as governor general for about a year. He had been governor general of British North America from 1861 to 1867. During that period, Monck strongly supported the Canadian confederation movement, which led to formation of the Dominion. He asked Sir John A. Macdonald, a confederation leader, to be the Dominion's first prime minister.

Charles Stanley Monck was born Oct. 10, 1819, in Tipperary, Ireland. He became the fourth Viscount Monck in 1849. A Liberal, he was elected to the British House of Commons in 1852. He was a lord of the treasury from 1855 to 1858 in the government led by Viscount Palmerston. Monck was knighted in 1869. Jacques Monet

Moncton, *MUHNGK tuhn,* New Brunswick (pop. 61,046), is eastern Canada's main transportation and distribution center. Moncton lies on the Petitcodiac River in southeastern New Brunswick, near the Bay of Fundy (see **New Brunswick** [political map]). Moncton is sometimes called the "hub of the Maritime Provinces." Railroads in and out of the Maritime Provinces—that is, New Brunswick, Nova Scotia, and Prince Edward Island—pass through Moncton. In addition, the city lies on the Trans-Canada Highway and has an international airport.

Many of the city's workers have jobs buying, selling, storing, or moving goods. Several large Canadian companies have call centers in Moncton, and these centers employ thousands of workers to handle service calls and telemarketing. Food processing and the manufacture of communications equipment are also important.

Moncton is home to the University of Moncton. The city also has an indoor amusement park, a water park, and a zoo. The famous Tidal Bore of the Petitcodiac River rolls up from the Bay of Fundy and rushes past Moncton twice a day. This wall of water measures about 24 inches (61 centimeters) high.

Originally a shipbuilding center, Moncton was incorporated as a city in 1890. It has a mayor-council form of government. Edith Robb

Mondale, Walter Frederick (1928-   ), was vice president of the United States from 1977 to 1981 under President Jimmy Carter. Before becoming vice president, Mondale had been a U.S. senator from Minnesota. He was known as a liberal who supported government action in many fields. Mondale was the Democratic nominee for president in 1984. He lost to his Republican opponent, President Ronald Reagan.

Wide World
Walter F. Mondale

Early life. Mondale was born Jan. 5, 1928, in Ceylon, Minnesota, the son of a Methodist minister. Walter, the sixth of seven children, was nicknamed Fritz as a boy. He graduated from the University of Minnesota and from the university's law school. Until 1960, he practiced law in Minneapolis. In 1955, he married Joan Adams of St. Paul, Minnesota. They had three children: Theodore, the oldest; Eleanor Jane; and William, the youngest.

Political career. Mondale began his political career in May 1960, when Governor Orville L. Freeman of Minnesota appointed him attorney general of the state. Mondale had managed Freeman's third successful campaign for the governorship. Mondale was elected to a full term as state attorney general in November 1960 and won reelection in 1962.

In 1964, Governor Karl F. Rolvaag appointed Mondale to the U.S. Senate to replace Hubert H. Humphrey, who had been elected vice president of the United States. Mondale won election to a full term in 1966 and was reelected in 1972. As a senator, Mondale became known for his liberal views. He voted for bills that favored civil rights, consumer protection, education reform, and campaign financing reform.

The 1976 Democratic National Convention nominated Mondale for vice president. In the election, Carter and Mondale defeated their Republican opponents, President Gerald R. Ford and Senator Robert J. Dole of Kansas. As vice president, Mondale's duties included visiting foreign nations and advising Carter.

In the 1980 presidential election, Carter and Mondale again became the Democratic nominees. But they were defeated by their Republican opponents, Ronald Reagan and George H. W. Bush. In 1984, the Democratic National Convention nominated Mondale for president and, at his request, Representative Geraldine A. Ferraro of New York for vice president. Ferraro was the first woman ever chosen for the vice presidency by a major U.S. political party. In the election, Mondale and Ferraro were defeated by Reagan and Bush. From 1993 to 1996, Mondale served as U.S. ambassador to Japan under President Bill Clinton. Finlay Lewis

Monday is the second day of the week. The word comes from the Anglo-Saxon *mōnandaeg,* which means the *moon's day.* In ancient times, each day of the week was dedicated to a god or goddess. Monday was sacred to the goddess of the moon. *Black Monday* is the name given to Easter Monday, April 14, 1360. On this day, many of the troops of King Edward III of England, who were fighting the French, died on horseback outside Paris due to cold weather. *Blue Monday* is a term used in the United States to indicate that it is a dismal day. It is the day the workweek begins. See also **Labor Day; Week.** Jack Santino

Mondrian, *MAWN dree ahn,* **Piet,** *peet* (1872-1944), was a Dutch painter. He became known for his extremely simplified geometric style. He developed this style from about 1910 to 1920 and continued to refine it throughout his career. Mondrian influenced modern architecture and commercial design as well as painting.

Mondrian balanced a small number of unequal rectangles of pure primary colors (red, yellow, and blue) as well as black, white, and gray. He arranged the shapes in horizontal and vertical relationships. Typically, Mon-

drian bounded these rectangles with black edges or lines. But his last paintings have colored lines and more numerous, smaller rectangles. Most of his paintings feature smooth surfaces with no visible brushstrokes. His *Composition* is reproduced in the **Painting** article.

Mondrian called his abstract style *neoplasticism.* It is often associated with *De Stijl (The Style),* a magazine Mondrian helped establish. He regarded neoplasticism as an ideal model for the unification of the arts that would provide a morally sound environment of order and beauty.

Mondrian was born in Amersfoort, the Netherlands. He lived primarily in Paris from 1912 to 1938. In 1940, he settled in New York City, where he died. Nancy J. Troy

Monel metal, *moh NEHL,* is an important alloy of nickel and copper. It contains about 67 percent nickel and 30 percent copper. The rest is made up of such elements as aluminum, iron, manganese, or titanium. Monel metal looks like nickel. It is about as hard as steel and can be forged and drawn into wire or other shapes. It is easier to prepare than nickel, for some ores already contain nickel and copper in suitable proportions. Thus, the alloy is sometimes cheaper than pure nickel.

Monel metal generally resists corrosion, showing little damage from steam, seawater, hot gas, air, or acids. This property makes it very useful in sheet-metal work, in chemical plants, and on ships. It is used for pump fittings, propellers, and condenser tubes; as a covering for sinks and soda fountains; and for containing and transporting acids. I. Melvin Bernstein

Moneran. See **Prokaryote**.

Monet, *moh NAY* or *maw NEH,* **Claude** (1840-1926), a French painter, was a leader of the Impressionist movement. He influenced art by trying to paint his personal, spontaneous response to outdoor scenes or events. Earlier artists had also painted outdoor studies rapidly—almost in shorthand. But they used such studies as "notes" for more elaborate pictures painted in the studio. Monet was the most important of the artists who first allowed their initial impressions of outdoor scenes to stand as complete works. He was especially concerned with the effect of outdoor light and atmosphere. This concern can be seen in his *La Grenouillère* (1869) and *Old St. Lazare Station, Paris* (1877).

Monet was born in Paris. In 1874, he exhibited a landscape called *Impression: Sunrise* (1872) in a show. This patchily textured work caused one critic to skeptically call the entire show *impressionist,* which gave the movement its name. See **Impressionism**.

Monet's fascination with light led him to paint several series of pictures showing the effect of sunlight on a subject. For example, he painted views of a cathedral or of a haystack under changing atmospheric conditions and at different hours of the day. An example, *Rouen Cathedral, Full Sunlight,* appears in the **Painting** article.

In 1883, Monet settled in Giverny, located near Vernon. There, at his country home, he painted garden scenes. In addition, he painted a series of large pictures of water lilies. The freely brushed colors of the lilies influenced later abstract painters. Richard Shiff

Monet's *Water Lilies* is one of a series the artist painted near the end of his life, when he was almost blind. The emphasis on light and color gives the picture an almost abstract quality.

Bills and coins from around the world look different and have different names. The money from nearly all countries consists of paper or of copper, nickel, and other metals that have little value by themselves. Euro notes and coins replaced a number of traditional European currencies in 2002.

Money

Money is anything that is generally accepted by people in exchange for the things they sell or the work they do. Gold and silver were once the most common forms of money. But today, money consists mainly of paper bills, metal coins, and checking account deposits.

Each country has a basic unit of money. In the United States, for example, the basic unit is the U.S. dollar. Canada uses the Canadian dollar, Japan the yen, Mexico the new peso, Russia the ruble, Switzerland the franc, and the United Kingdom the pound. Many European countries use the euro. The money in use in a country is called its *currency.*

The contributors of this article are R. G. Doty, Curator of the National Numismatic Collection of the Smithsonian Institution; and Stanley Fischer, First Deputy Managing Director, International Monetary Fund. The photographs for this article were taken for World Book *by James Simek, unless otherwise credited. Some rare examples of money were provided through the courtesy of Deak-Perera Chicago, Inc.; the Rare Coin Company of America, Inc.; and the Jeffery S. Zarit Company. Current U.S. paper money pictured in this article is shown in black and white because color reproduction is prohibited by law.*

Money has three main uses. First, and most important, it is a *medium of exchange*—that is, something people will accept for their goods or services. Without a medium of exchange, people would have to trade their goods or services directly for other goods or services. If you wanted a bicycle, you would have to find a bicycle owner willing to trade. Suppose the bicycle owner wanted skis in exchange for the bike and you did not own skis. You would then have to find something a ski owner or ski maker wanted and trade it for skis to give the bicycle owner. Such trading, called *barter,* can take much time. A modern, industrialized country could not function without a medium of exchange.

A second use of money is that it serves as a *unit of account.* People state the price of goods and services in terms of money. In the United States, people use dollars to specify price, just as they use hours to express time and miles or kilometers to measure distance.

A third use of money is as a *store of wealth.* People can save money and then use it to make purchases in the future. Other stores of wealth include gold, jewels, paintings, real estate, and stocks and bonds.

Christiana Dittmann, Rainbow

Barter at a Peruvian marketplace

Cowrie shells (Africa, Asia, and Australia)

Fishhook (Northwest Coast of North America)

Trade beads (Africa)

The development of money began as people came to accept certain goods as mediums of exchange. Before then, all people, like those at the upper left, used *barter* (the exchange of goods for other goods) to get what they wanted. The other pictures show former mediums of exchange.

Any object or substance that serves as a medium of exchange, a unit of account, and a store of wealth is money. To be convenient, however, money should have several qualities. It should come in pieces of standard value so that it does not have to be weighed or measured every time it is used. It should be easy to carry so that people can carry enough money to buy what they need. Finally, it should divide into units so that people can make small purchases and receive change.

In the past, people used beads, cocoa beans, salt, shells, stones, tobacco, and other things as money. But above all, they used such metals as copper, gold, and silver. These metals made convenient, durable money.

Today, most money consists of paper. The paper itself is of little value, but it is accepted in exchange. People accept pieces of metal or paper in exchange for work or goods for only one reason: They know that others will take the same metal or paper in exchange for the things they want. The value of money therefore results from the fact that everyone will accept it as payment.

How money developed

Early people had no system of money as we know it. To get the things they wanted, people used the barter system of trading. Gradually, people learned that almost everyone would accept certain goods in exchange for any product or service. These goods included animal hides, cattle, cloth, salt, and articles of gold or silver. People began to use such merchandise as mediums of exchange, much as we use money.

Many people still use barter, especially in the developing countries of Africa, Asia, and Latin America. Millions of families in these countries live by farming and produce barely enough food to meet their own needs. As a result, they seldom acquire any money and must use barter to obtain the things they want. People in industrial countries also turn to barter if money becomes scarce or worthless. For example, barter became widespread in Germany after the country's defeat in World War II (1939-1945). German money became almost worthless, and people refused to take it. Instead, they bartered for most goods and services. They also used cigarettes, coffee, and sugar, which were in short supply, as mediums of exchange.

The first coins may have been made during the 600's B.C. in Lydia, a country in what is now western Turkey. The coins were bean-shaped lumps of *electrum,* a natural mixture of gold and silver. The coins had a stamped

design to show that the king of Lydia guaranteed them to be of uniform value. The designs saved people the trouble of weighing each coin to determine its value. Traders accepted these coins instead of cattle, cloth, gold dust, or other goods as a medium of exchange. Other countries saw the advantages of the Lydian coins and began to make their own coins.

Many historians believe that coins were also invented independently in ancient China and in India. At first, the Chinese used knives, spades, and other metal tools as mediums of exchange. As early as 1100 B.C., they began to use miniature bronze tools instead of real ones. In time, the little tools developed into coins.

Coins today have many of the same features that they had in ancient times. For example, they have a government-approved design stamped on them, like the coins of ancient Lydia.

The development of paper money began in China, probably during the A.D. 600's. The Italian trader Marco Polo traveled to China in the 1200's and was amazed to see the Chinese using paper money instead of coins. In a book about his travels, Polo wrote: "All his [the Chinese emperor's] subjects receive it [paper money] without hesitation because, wherever their business may call them, they can dispose of it again in the purchase of merchandise they may require."

In spite of Polo's description, Europeans could not understand how a piece of paper could be valuable. They did not adopt the use of paper money until the 1600's, when banks began to issue paper bills, called *bank notes,* to depositors and borrowers. The notes could be exchanged for gold or silver coins on deposit in the bank. Until the 1800's, most of the paper bills in circulation were notes issued by banks or private companies rather than by governments.

Some of the first paper currency in North America consisted of playing cards. This playing-card money was introduced in Canada in 1685. Canada was then a French

The first coins and bills

One of the first coins was this bean-shaped gold *stater, above.* It was made in Lydia during the 500's B.C.

Miniature tools, such as the spade and hoe at the right, were mediums of exchange in China as early as 1100 B.C.

An ancient Greek coin called a *tetradrachm* was issued during the 400's B.C. The front of the coin, *above left,* had a portrait of the goddess Athena. An owl was stamped on the back, *above right.*

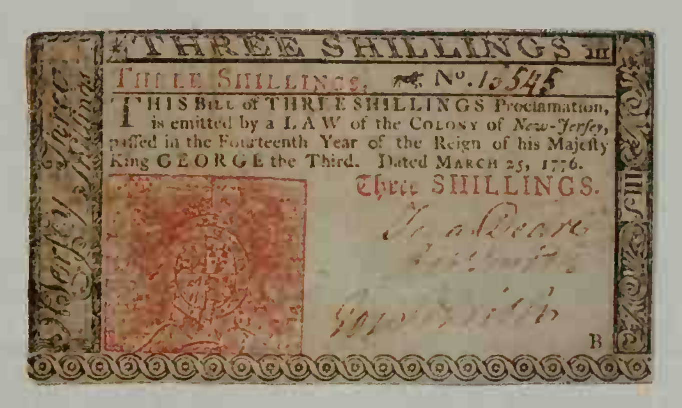
Paper money was first used in China. This bill was printed on bark paper in the 1300's.

National Currency Collection, Bank of Canada

Playing-card money was used in Canada when it was a French colony during the 1600's and 1700's. The colonial governor signed the back of each card.

Money in the American Colonies

Money was scarce in the American Colonies. Paper currency was seldom used, and the British did not allow the colonies to mint coins. As a result, the colonists used any foreign coins they could get. Indian wampum and other goods also circulated as money.



Wampum, which consisted of beads made from shells, was used by the Indians to decorate garments and keep records. The colonists, who had few coins, used it as money. Most wampum was made into necklaces or belts.

The oak-tree shilling was one of the first coins made in Massachusetts. The colony began to issue coins like the one above in 1660.

The escudo was used throughout the Americas. The 8-escudo coin above was minted in the reign of King Ferdinand VI of Spain.

A 3-shilling note, *left,* was issued by the colony of New Jersey in 1776. A number of colonies issued their own paper currency.

colony. Money to pay the French soldiers stationed there had to be shipped from France. Shipments were often delayed, however, and cash grew so scarce that the colonial government began to issue playing cards as currency. Each card was marked a certain value and signed by the governor. Such playing-card money circulated for more than 70 years.

History of United States currency

In the American Colonies, money was scarce. England did not furnish coins and forbade the colonies to make them. The English hoped to force the colonies to trade almost entirely with England. One way of doing so was by limiting the money supply. Without money, the colonists could not do business with traders in other countries who demanded payment in cash. But the colonists could buy products from English traders with *bills of exchange.* They got these documents from other English traders in exchange for their own goods.

The American colonists used a variety of goods in place of money. These goods included beaver pelts, grain, musket balls, and nails. Some colonists, especially in the tobacco-growing colonies of Maryland and Virginia, circulated receipts for tobacco stored in warehouses. Indian wampum, which consisted of beads made from shells, was mainly used for keeping records. But Indians and colonists also accepted it as money.

The colonists also used any foreign coins they could get. English shillings, Spanish dollars, and French and Dutch coins all circulated in the colonies. Probably the most common coins were large silver Spanish dollars called *pieces of eight.* To make change, a person could chop the coin into eight pie-shaped pieces called *bits.* Two bits were worth a quarter of a dollar, four bits a half dollar, and so on. We still use the expression *two bits* to mean a quarter of a dollar.

In 1652, the Massachusetts Bay Colony became the first colony to make coins. It produced several kinds of silver coins, including a *pine-tree shilling* and an *oak-tree shilling,* which were stamped with a tree design. Massachusetts continued to issue coins for 30 years in defiance of an English law that said only the monarch could issue them. The colony dated all coins 1652, no matter when they were made, probably to get around the law. In 1652, there was no monarch in England. Thus, the colonists could claim the coins were minted at a time when royal authority did not exist.

Massachusetts also became the first colony to produce paper money. In 1690, the colonial government issued notes called *bills of credit.* The bills were receipts for loans made by citizens to the colonial government. Massachusetts used the bills to help finance the first French and Indian war, a war between English and French colonists for control of eastern North America.

The first United States currency. During the mid-1700's, Great Britain tried to tighten its control over the American Colonies with new taxes, stricter trade regulations, and other laws. Friction between the Americans and the British mounted. In 1775, the Revolutionary War broke out between the two sides. The next year, colonial leaders meeting as the Second Continental Congress declared independence and founded the United States of America. To help finance the war for independence, each state and the Continental Congress began to issue paper money.

As war expenses mounted, the states and Congress printed more and more money. Congress itself issued about $240 million in notes called *continentals.* So many continentals were printed that by 1780 they were almost worthless. Americans began to describe any useless thing as "not worth a continental." The experience with continentals was so bad that the U.S. government did not again issue paper currency for widespread use until the 1860's.

The United States won the Revolutionary War in 1783, but the struggle left the American monetary system in disorder. Most of the currencies circulated by the states had little value. The U.S. Constitution, adopted in 1788, corrected this problem by giving Congress the sole power to coin money and regulate its value. In 1792, an act of Congress set up the first national money system in the United States. The act made the dollar the basic unit of money. It also put the nation on a system called the *bimetallic standard,* which meant that both gold and silver were legal money. The value of each metal in relation to the other was fixed by law. For years, 16 ounces (448 grams) of silver equaled 1 ounce (28 grams) of gold.

The act also established a national mint in Philadel-

Money in the new nation

Continental currency was issued by the Continental Congress to help finance the Revolutionary War (1775-1783). So many of these notes were printed that they became almost worthless.

The écu, a French coin, was one of many foreign coins that circulated in the United States after the nation won independence. A 1793 law made these coins part of the U.S. monetary system.

The Spanish dollar, or piece of eight, was another foreign coin that circulated in the new nation. The coin shown at the far left and center was minted in Mexico in 1790. These dollars could be chopped into eight pieces, called *bits,* or into quarters, *near left,* called *two bits.*

A $10 gold piece called an *eagle* was issued by the U.S. Mint from 1795 to 1933. The eagle shown above dates from 1795. It has a liberty cap on the front and an eagle on the back.

Bank notes were the most common paper money in the United States until the 1860's. Banks vowed to exchange their notes for gold or silver. The State Bank of Illinois issued this note in 1840.

phia. The mint produced $10 gold coins called *eagles,* silver dollars, and other coins.

Americans continued to use many foreign coins in addition to their new currency. A law passed in 1793 made these coins part of the U.S. monetary system. The value of a foreign coin depended on how much gold or silver it had. In 1857, Congress passed a law removing foreign coins from circulation.

The rebirth of paper money. During the early 1800's, the only paper money in the United States consisted of hundreds of kinds of bank notes. Each bank promised to exchange its notes on demand for gold or silver coins. But numerous banks did not keep enough coins to redeem their notes. Many notes therefore were not worth their *face value*—that is, the value stated on them. As a result, people hesitated to accept bank notes.

The soundest bank notes of the early 1800's were issued by the two national banks chartered by the U.S. government. The First Bank of the United States was chartered by Congress from 1791 to 1811, and the Second Bank of the United States from 1816 to 1836. Both banks supported their notes with reserves of gold coins, and people considered the notes as good as gold.

Paper money as we know it today dates from the 1860's. To help pay the costs of the American Civil War (1861-1865), the U.S. government issued about $430 million in paper money. The money could not be exchanged for gold or silver. The bills were called *legal tender notes* or *United States notes.* But most people called them *greenbacks* because the backs were printed in green. The government declared that greenbacks were *legal tender*—that is, money people must accept in payment of public and private debts. Nevertheless, the value of greenbacks depended on people's confidence in the government. That confidence rose and fell with the victories and defeats of the North in the Civil War. At one time, each greenback dollar was worth only 35 cents in gold coin. In the South, the Confederate States also issued paper money. It quickly became almost worthless.

In 1863 and 1864, Congress passed the National Bank Acts, which set up a system of privately owned banks chartered by the federal government. These national banks issued notes backed by U.S. government bonds. Congress also taxed state bank notes to discourage their use. As a result, national bank notes became the country's chief currency.

Some greenbacks also continued to circulate. The government announced that, beginning in 1879, it would pay gold coins for greenbacks. The U.S. Department of the Treasury gathered enough gold to redeem all the greenbacks likely to be brought in. But as soon as people knew they could exchange their greenbacks for gold, they were not anxious to do so. The fact that the Treasury paid out only gold coins meant the country was operating on an unofficial *gold standard,* rather than the bimetallic standard of the early 1800's. The gold standard is a system in which a nation defines its basic monetary unit as worth a certain quantity of gold and agrees to redeem its money in gold on demand.

The new national banks system eliminated the confusion that had existed when hundreds of different bank notes were in circulation. But the system did not provide for the federal government to increase the supply of money when needed. Shortages of money contributed to a series of economic slumps during the late 1800's. Many people called for the government to provide more money by coining unlimited amounts of silver. Such a policy was called *free silver,* and the argument over free silver became an important political issue.

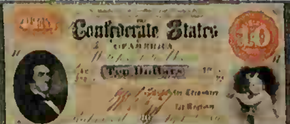
The dispute reached a climax during the presidential election of 1896. The Republican candidate, William McKinley, favored the gold standard. McKinley defeated William Jennings Bryan, the Democratic candidate, who supported free silver (see **Free silver**). In 1900, Congress passed the Gold Standard Act, which officially put the nation on a gold standard. The United States went on and off the gold standard several times and finally abandoned it in 1971 (see **Gold standard**).

The United States suffered from repeated monetary difficulties until 1913, when Congress passed the Federal Reserve Act. This act created the Federal Reserve System, a central banking system that helps manage the economy by influencing interest rates and the availability of money and loans.

United States currency today consists of coins and paper money. Under federal law, only the Department of the Treasury and the Federal Reserve System may issue U.S. currency. The Treasury issues all coins. The Federal Reserve issues paper currency called *Federal*

Later United States money

U.S. currency of the 1800's and early 1900's included silver coins, gold pieces, and various types of paper money. Many bills, including gold and silver certificates, could be exchanged for gold or silver coins on demand. The use of these two metals as money is called the *bimetallic standard.*



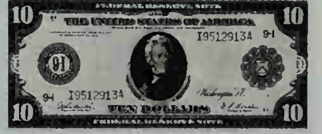
Silver dollar (1800)

U.S. Assay Office $50 gold piece (1851)

$20 gold double eagle (1865)

Confederate $10 bill (1861)

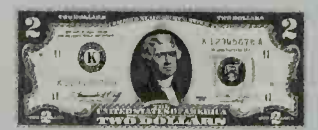
$5 legal tender note (about 1862)



$50 gold certificate (about 1882)

$20 national bank note (about 1882)

$50 silver certificate (about 1891)



Federal Reserve $10 bill (about 1914)

Federal Reserve notes

Federal Reserve notes make up nearly all the paper money in the United States. The notes are issued by the 12 Federal Reserve Banks in the Federal Reserve System. The photographs here show the front and back of the seven traditional bills: $1, $2, $5, $10, $20, $50, and $100.

Large U.S. bills include Federal Reserve notes in denominations of $500, $1,000, $5,000, and $10,000. The government began withdrawing such bills from circulation in 1969.

Reserve notes. All U.S. currency carries the nation's official motto, *In God We Trust.*

Coins come in six *denominations* (values). These are (1) penny, or 1 cent; (2) nickel, or 5 cents; (3) dime, or 10 cents; (4) quarter, or 25 cents; (5) half dollar, or 50 cents; and (6) $1. All coins are made of *alloys* (mixtures of metals). Pennies are copper-coated zinc. Nickels are a mixture of copper and nickel. Dimes, quarters, half dollars, and dollars are made of three layers of metal. The core is pure copper. The outer layers of dimes, quarters, half dollars, and Susan B. Anthony dollars are an alloy of copper and nickel. The outer layers of golden dollars are an alloy of copper, zinc, manganese, and nickel.

Dimes, quarters, half dollars, and Susan B. Anthony dollars have ridges called *reeding* or *milling* around the edge. The reeding on a dime distinguishes it from a penny, which has a smooth edge. Coins must be dated with the year they were made and must bear the word *Liberty* and the Latin motto *E Pluribus Unum,* meaning *out of many, one.* This motto refers to the creation of the United States from the original Thirteen Colonies.

Mints in Denver and Philadelphia make most coins for general circulation. Mints in San Francisco and West

Point, New York, make mostly commemorative coins to mark special occasions, and gold and silver bullion coins for investors. People buy bullion coins for the value of the metal they contain. Coins made in Denver are marked with a small *D.* A *P* appears on most coins made in Philadelphia. Some coins made in San Francisco are marked with an *S,* and some made in West Point are marked with a *W.*

Paper money. Federal Reserve notes make up nearly all the paper money in the United States. Hundreds of billions of dollars of these notes are in circulation. They come in seven denominations: $1, $2, $5, $10, $20, $50, and $100. The notes are issued by the 12 Federal Reserve Banks in the Federal Reserve System. Each note has markings that identify the bank which issued it. In addition, each note bears the words *Federal Reserve note* and a green Treasury seal. Until 1969, Federal Reserve Banks also issued notes in four large denominations: $500, $1,000, $5,000, and $10,000.

Other paper money circulating in the United States includes United States notes. These notes, last printed in 1968, are the descendants of Civil War greenbacks. United States notes carry the words *United States note* and a red Treasury Department seal. All Federal Reserve and United States notes bear the printed signatures of the persons who were secretary of the treasury and treasurer of the United States at the time the notes were issued.

In the 1990's, the United States began issuing redesigned Federal Reserve notes, starting with a new $100 bill in 1996. The government planned eventually to issue new bills for all denominations. Plans called for issuing about one redesigned denomination each year, beginning with the largest denominations and ending with the smallest. The new bills have features intended to make them harder to counterfeit. These features include a special watermark and a "security thread" that glows in the dark when exposed to ultraviolet light.

The government announced that the Federal Reserve would gradually remove all the old Federal Reserve notes from circulation. However, the government placed no time limit on the removal. The old bills would keep their full face value for as long as they remained in

How coins are made The United States Mint makes all U.S. coins. Bars of metal are rolled into strips about the thickness of the finished coins. A machine punches coin-sized disks, called *blanks,* out of the metal strips. The blanks are fed into a *coining press,* which stamps a design on both sides of each blank.

Designing a new coin starts with a number of sketches. After a design has been selected, an artist makes a large model of the coin.

Reducing the design to coin size is done by a *reducing lathe.* This machine traces the model coin and carves it in miniature on a steel *hub.*

Cutting the hub is done by a sharp tool on the other end of the reducing lathe. The hub is heat-treated and used to make a set of coin-stamping *dies.*

Screening the blanks removes imperfect ones. The perfect blanks are fed into the coining press, which uses the coin-stamping dies to produce the design.

Inspecting the newly minted coins helps find defective ones. Imperfect coins are melted down, and the metal is then used over again.

Photos Courtesy of the United States Mint, Philadelph

Counting and bagging the finished coins is done by machines. The mint ships the coins to Federal Reserve Banks for distribution to the public.

circulation. For photographs of the old bills and of the new ones issued so far, see the *Federal Reserve notes* illustration with this article.

How money is manufactured

Two agencies of the U.S. Department of the Treasury manufacture currency. The United States Mint makes coins, and the Bureau of Engraving and Printing produces paper money.

Minting coins. The production of a new coin begins with artists' proposed designs for the coin. After government officials select a design, an artist constructs a large clay model of the coin. Most models are about eight times the size of the finished coin. The artist does not add details because the clay is too soft. Instead, the artist makes a mold of the clay model and then makes a plaster cast from the mold. The plaster is hard enough to enable the artist to carve fine details. A machine called a *reducing lathe* traces the finished plaster model and carves the design, reduced to coin size, onto a soft piece of steel called a *master hub*. The master hub is heat-treated to harden it. A special machine takes an impression of the hub to make a set of steel tools called *master dies*. These dies are used to stamp copies of the master hub called *working hubs*. The working hubs are employed, in turn, to make *working dies*, which stamp the coins. The master hub and master dies are stored and used to make more hubs and dies after the first ones wear out.

Bars of metal are heated and squeezed between heavy rollers into strips the thickness of a coin. A machine punches out smooth disks of metal, called *blanks*, from the strips. The blanks are the size of coins but have no design. The blanks are fed into an *upsetting machine*, which puts a raised rim around the edge of each one. Then, they are fed into a *coining press*. The press uses two working dies to impress the coin's design on both sides of each blank in one operation. The press also reeds the edge of all coins except pennies and nickels.

The mint ships the finished coins to Federal Reserve Banks for distribution to commercial banks. The Reserve Banks also remove worn and damaged coins from circu-

How paper money is made

The Bureau of Engraving and Printing makes all U.S. paper currency. The bureau uses special paper and ink that have been manufactured to its specifications to produce long-lasting money. High-speed presses print sheets of 32 bills each. The sheets are then cut into separate bills.

Designing a new bill begins with a number of artist's drawings. The United States secretary of the treasury must approve the final design for a new bill.

Making an engraving. An engraver cuts the design into a steel plate. A machine called a *transfer press* copies the engraving 32 times on a printing plate.

Inspecting the printing plate ensures that it has no flaws. During printing, paper will be forced into the engraved lines of the plate to pick up ink.

Printing is done by fast presses that print thousands of sheets an hour. Separate plates print the front and back of the bills. Serial numbers are added later.

Inspecting the new bills. The printed sheets are cut in half and examined. The inspectors mark any imperfect bills. Later, such bills are replaced.

Bureau of Engraving and Printing (WORLD BOOK photos)

Counting and stacking are done by a machine that puts the bills in order of their serial numbers and bands them in stacks of 100 for delivery to banks.

lation. The mint melts these coins and uses the metal to make new coins.

Printing paper money. The production of a new bill begins when artists sketch their designs for it. The secretary of the treasury must approve the final design. Engravers cut the design into a steel plate. A machine called a *transfer press* squeezes the engraving against a soft steel roller, making a raised design on its surface. After the roller is heat-treated to harden it, another transfer press reproduces the design from the roller 32 times on a printing plate. Each plate prints a sheet of 32 bills. Separate plates print the two sides of the bills.

Many people believe the paper used for money is made by a secret process. But the government publishes a detailed description of the paper so private companies can compete for the contract to manufacture it. A U.S. law forbids unauthorized people to make any type of paper similar to that used for money.

The Bureau of Engraving and Printing uses high-speed presses to print sheets of paper currency. The design is printed first. Then the seals and serial numbers are added. The sheets are cut into stacks of bills. Imperfect bills are replaced with new ones called *star notes.* Each star note has the same serial number as the bill it replaces, but a star after the number shows that it is a replacement bill. The bills are shipped to Reserve Banks, which distribute them to commercial banks.

Most $1 bills wear out after about 18 months in circulation. Larger denominations last for years because they are handled less often. Banks collect worn-out bills and ship them to Federal Reserve Banks for replacement. The Reserve Banks destroy worn-out money in shredding machines.

Money and the economy

The quantity of money in a country affects the level of prices, the rate of economic growth, and therefore the amount of employment. If the money supply increases, people have extra money to buy things, and their demand for products grows. In response to the growing demand, manufacturers hire more workers to increase output. Earnings rise and spending increases, leading to further economic growth. However, if output cannot keep pace with demand, prices will increase. A continuing rise in prices is called *inflation.* Inflation may cause problems for people whose income does not keep pace with rising prices. If the money supply shrinks, people have less to spend. Goods and services remain unsold. Prices fall. Manufacturers cut back on production, and many businesses lay off workers.

The main economic goals of nearly all nations are to promote economic growth and high employment with a minimum increase in prices. A government's chief methods of promoting these goals are by its *monetary policy* and its *fiscal policy.* Monetary policy refers to how a government influences such factors as interest rates, the availability of loans, and the money supply. Fiscal policy refers to a government's taxing and spending programs. To stimulate the economy, a government may reduce interest rates, increase the money supply, reduce taxes, or boost its own spending. The following discussion focuses on monetary policy. For details on fiscal policy, see Economics (Economic stability).

The value of money is defined by economists as the quantity of goods and services that the money will buy. If prices go up or down, the value of money also changes. A major aim of any government's monetary policy is to keep prices stable and thus preserve the value of money, also called its *purchasing power.* Today, people worry most about inflation, which lowers the value of money. If prices double, for example, a dollar buys only half as much as before, and so the value of money has dropped one-half. The *rate of inflation* is the rate at which prices in general are rising and the rate at which the value of money is falling.

Rapid, uncontrolled inflation can severely damage a country's economy. For example, prices in Germany increased 10 billion times from August 1922 to November 1923. Such severe inflation is called *hyperinflation.* The value of the German mark dropped so sharply and so rapidly that employers paid workers twice a day. Marks became so worthless that no one would take them, and people began to use barter instead of money. Employers paid workers by giving them some of the goods they produced. People spent so much time trading for the things they needed that production nearly came to a halt. The hyperinflation ended after the government introduced a new currency.

Inflation has many causes. But in most cases, prices cannot continue to rise without increases in the quantity of money. There never has been severe inflation without a large expansion in a nation's money supply.

Definitions of the money supply. The money supply includes more than just coins and paper money. In fact, checking account deposits are the most common form of money in the United States and many other countries. In the United States, about three-fourths of all payments are made by check. Checks are a safe and convenient medium of exchange. In addition, a canceled check provides written proof that payment was made.

Economists define the money supply in various ways, depending on which assets they include in their measurements. The definitions change as the banking system changes. Two major definitions of the U.S. money supply are called M-1 and M-2.

M-1 consists of checking account deposits, also called *demand deposits;* traveler's checks; and currency. In the mid-1990's, M-1 totaled about $1,125 billion.

M-2 consists of M-1 plus money invested in savings accounts at commercial banks, at savings banks, and at savings and loan associations. Such savings, called *time deposits,* are not immediately available to make purchases. The saver first has to withdraw the money, and the bank can require advance notice of withdrawal. However, most people can easily convert their savings to cash or checking deposits. M-2 amounted to about $3,560 billion in the mid-1990's.

How the money supply is determined. The size of a nation's money supply is determined differently if the nation uses *commodity money* or *fiat money.* Commodity money typically consists of valuable metals, especially gold or silver. Fiat money, typically paper money or coins, is of less value as a commodity than as money. It has value as money because people are willing to accept it. To increase the chance of people accepting its money, a government may make the currency legal tender. Then, the law requires people to accept the money at face value.

If a nation uses commodity money, the money supply is determined by the cost of producing the metal and the rate of production. During the late 1800's and the early 1900's, the United States and many other countries were on the gold standard, which is a commodity money system. Each nation promised to redeem its currency for a specified amount of gold. For example, a United States dollar was officially valued at about 26 grains (1.7 grams) of gold. The amount of money that countries could issue depended on how much gold was being mined in the world. A decline in gold output during the 1870's and the 1880's slowed the growth of the money supply and caused prices to fall. The economic problems ended only after the discovery of new gold fields in South Africa and after the invention of a more efficient method of extracting gold from the rocks in which it is found.

The United States and most other countries today are on the fiat money system. Under this system, the money supply does not depend on the production of any commodity. Instead, the national government largely determines the money supply through its monetary policy.

How the Federal Reserve System influences the money supply

Actions of the Federal Reserve System, the central bank of the United States, can influence the nation's money supply. This chart shows how actions of the Federal Reserve can put more money into circulation. Opposite actions tend to shrink the money supply.

WORLD BOOK diagram by David Cunningham

The Board of Governors of the Federal Reserve System reviews data on employment, industrial output, inflation, and other economic trends. It decides to expand the economy.

The discount rate is the interest rate banks pay to borrow from the Federal Reserve. Lowering the rate encourages banks to grant loans.

Open-market operations involve buying and selling government securities. To boost the economy, the Federal Reserve buys securities.

The reserve requirement is the amount of money banks must keep on reserve. Lowering the requirement lets banks make more loans.

An open-market trader of the Federal Reserve buys securities from dealers and pays by check. The dealers deposit the checks in their banks, which must put part of the money on reserve but can lend the rest.

The money supply tends to expand when banks make more loans due to a lower discount rate or reserve requirement, or an open-market purchase.

The monetary policy is conducted by the nation's *central bank,* which is a government agency in most countries. The central bank issues currency, regulates the activities of the nation's commercial banks, and performs other financial services for the government. The Federal Reserve System is the central bank of the United States. The central bank of Canada is the Bank of Canada. Other central banks include the Bank of England in the United Kingdom, the Banque de France in France, and the Deutsche Bundesbank in Germany.

The role of the Federal Reserve System. The Federal Reserve System, often called simply the *Fed,* has 12 regional Federal Reserve Banks. Each bank is responsible for a Federal Reserve District. Most large commercial banks belong to the system. They use the Reserve Bank in their district much as people use a bank in their community. Each member bank must keep a certain sum of money either as currency in its vaults or as deposits at its Reserve Bank. This sum is a percentage of the member bank's own deposits and is called a *reserve requirement.* The reserve requirement is set by the Federal Reserve. A bank may withdraw any excess deposits at the Reserve Bank to get currency when needed. It may also borrow from the Reserve Bank. The Federal Reserve has the authority to set reserve requirements for all deposit-taking institutions.

The Federal Reserve influences the economy largely by affecting interest rates. It works to control these rates in several ways. It may raise or lower reserve requirements. Or the Federal Reserve may raise or lower the discount rate, which is the interest rate commercial banks pay to borrow from Reserve Banks. Raising the reserve requirement or the discount rate lowers the ability of banks to make loans and thus tends to raise interest rates and shrink the money supply. Lowering the reserve requirement or the discount rate tends to have the opposite effect on interest rates and the money supply.

However, the Federal Reserve controls interest rates chiefly by buying and selling government securities. These activities are called open-market operations. If the Federal Reserve wants to reduce interest rates, it makes an open-market purchase. It buys government securities from banks and other businesses and from individuals. The Federal Reserve pays for the securities with a check. The sellers now have more money than before, and the amount of money in the economy has increased. Banks have more money to lend than before, and they lower their interest rates. When the sellers deposit the checks at their bank, interest rates may fall—and the supply of money may increase—further. To reduce interest rates, the Federal Reserve sells securities in an open-market sale. The money supply tends to shrink as a result.

Efforts to stabilize the economy by focusing on either interest rates or on the money supply may be ineffective because changes in these factors do not affect the economy immediately. If the effect of a change is long delayed, it may strike the economy at the wrong time. For example, the Federal Reserve might have decided to increase the money supply in the hope of reducing joblessness within six months. However, the drop in unemployment might not have come for a year or more, and it might have happened at a time when unemployment had already begun to fall for other reasons. Instead of reducing joblessness, the Federal Reserve's action might then have only fueled inflation.

The Federal Reserve's task is also difficult because it is likely to increase unemployment when it tries to reduce inflation, and vice versa. If the Federal Reserve fights inflation by increasing interest rates, and thus reducing the money supply, employers may cut back on production and more workers will lose their jobs. If the Federal Reserve reduces interest rates to create more jobs, price increases may follow. In such cases, the Federal Reserve may have difficulty deciding what to do. Some economists believe that the best way to fight inflation and unemployment is by a gradual, continuous increase in the money supply.

International finance

Much trade takes place between nations. For example, Americans buy French cheese and Japanese automobiles, and the French and Japanese buy American airplanes and blue jeans. Most imported goods must be paid for in the currency of the selling country. An automobile dealer in the United States who buys Japanese cars gets yen by buying them from a bank at the current *exchange rate.* An exchange rate is the price of one nation's currency expressed in terms of another country's currency. If the exchange rate were 100 yen to the U. S. dollar, the American would have to buy $12,000 in yen to pay for a Japanese auto that cost 1.2 million yen.

Exchange rates are determined in foreign exchange markets. The rates vary from day to day in relation to international demand for various currencies. If Americans buy more Japanese products, for example, the U.S. demand for yen increases and the yen rises in price against the dollar. This system is known as *floating exchange rates* or *flexible exchange rates.* But the United States and many other countries do not allow the rate for their currency to float freely. Each of these countries has holdings of foreign currency. If the exchange rate falls too far, the government will use some of its foreign holdings to buy enough of its own currency to stabilize the exchange rate.

The balance of payments is the difference between a nation's receipts of foreign currency and its expenditures of foreign currency. A nation's balance of payments affects its exchange rate. The world price of a country's currency tends to rise if the country's receipts exceed its expenditures. This condition is called a *balance-of-payments surplus.* A nation's currency will tend to decline on world markets if more money flows out of the country than comes in. This condition is called a *balance-of-payments deficit.*

The primary influences on the balance of payments are income levels and rates of inflation. Suppose income levels rise more quickly abroad than in the United States. People in other countries then will increase their imports of American goods. The United States will export more than it imports, creating a balance-of-payments surplus and causing the world price of U.S. dollars to increase. If inflation causes prices to rise more quickly in the United States than abroad, foreign goods become cheaper for Americans to buy and they import more. This situation creates a balance-of-payments deficit and causes the U.S. dollar to drop in price.

International reserves. A large number of countries use official holdings of foreign currency to stabilize ex-

Independent countries and their currencies

This table lists major and minor currencies for most of the independent countries of the world. The number before each minor currency represents how many units of that currency equal one unit of the major currency. For example, 100 cents are equivalent to one dollar.

Country	Major currency	Minor currency
Afghanistan	afghani	100 pule
Albania	lek	100 qindarka
Algeria	dinar	100 centimes

*In January 2001, El Salvador's government adopted a plan to replace the colón with the U.S. dollar as the country's official currency.

change rates and to pay international debts. These holdings are called *international reserves.* The U.S. dollar plays a special role in international reserves, partly because the United States is one of the world's leading trading nations. Many countries keep nearly all their international reserves in U.S. dollars, and most countries are willing to accept payment in dollars. To some extent, the U.S. dollar thus functions as an international medium of exchange.

The International Monetary Fund (IMF) is an organization that works to improve financial dealings between countries. The International Monetary Fund has introduced a type of international reserves called *Special Drawing Rights* (SDR's). Member countries of the IMF can use these reserves to settle accounts among themselves. Unlike other reserves, SDR's exist only as entries on the account books of the IMF. Some economists think SDR's eventually will become widely used as an international medium of exchange.

Money market fund is a mutual fund that invests only in short-term securities. The term *money market* refers to the buying and selling of such securities. Money market funds are also known as *liquid asset funds, cash funds,* or *money funds.*

Numerous institutions need to borrow money for short periods—a year or less. Such institutions include the federal government, banks and other financial firms, and corporations. The securities that these institutions sell in the money market yield returns that are closely tied to current interest rates. Common types of money market securities include Treasury bills and certificates of deposit.

Like all other mutual funds, money market funds pool the money of many investors and pay them interest. The interest rate paid varies, depending on market condi-

tions. However, it usually exceeds the rate small investors get in savings accounts that have limits on interest rates.

The United States government does not insure the money in money market funds. However, money market funds invest mainly in low-risk securities and are considered safe.

Money market funds developed during the early 1970's. Their low initial investment, high yields, and safety led to spectacular growth. However, that trend ended in 1982, when the federal government allowed savings institutions to offer federally insured accounts that provided yields similar to those of money market funds. Today, there are more than 450 money market funds in the United States. Their net assets total more than $260 billion. Carol S. Greenwald

Money order is a document directing that a sum of money be paid to a certain person. Many banks and stores and all United States and Canadian post offices sell money orders for a small fee. Money orders resemble checks and thus provide a safe way to send money through the mail. A purchaser fills out a money order and mails it to the person he or she has indicated. The person receiving the order may cash it at a bank or post office.

U.S. postal money orders may be either domestic or international. A domestic money order may be sent anywhere within the United States. Domestic orders also may be sent to Antigua and Barbuda, the Bahamas, Barbados, Belize, the British Virgin Islands, Canada, Dominica, Grenada, Jamaica, Montserrat, St. Kitts and Nevis, St. Lucia, St. Vincent and the Grenadines, and Trinidad and Tobago. An international money order may be sent to any of the approximately 75 countries that honor them.

The highest face value of any single domestic or international money order is $700. No individual may purchase postal money orders exceeding $10,000 in face value on any day.

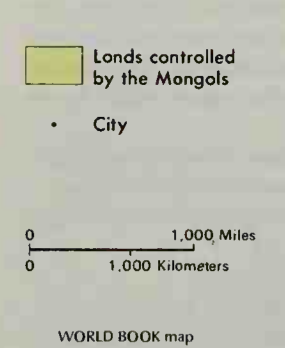
A postal money order may be cashed at any time after the date of issue. Postal money orders may be endorsed only once. The United States Postal Service refunds the value of its money orders if they are lost or stolen in the mail.

Canadian postal money orders cannot have a face value of more than $999.99 in Canadian dollars. However, an unlimited number of money orders may be purchased. Critically reviewed by the Canada Post Corporation and the U.S. Postal Service

Mongol Empire was the biggest land empire in history. Its territory extended from the Yellow Sea in east-

U.S Postal Service

A U.S. domestic postal money order can be purchased at any United States post office. The post office fills in the amount of the money order. The purchaser adds his or her name and address and the name and address of the person who should receive payment.



Canada Post Corporation

A Canadian postal money order is printed in both English and French. It has spaces for the sender's name and address and for the name of the person receiving the money.

The Mongol Empire covered most of Asia. It began under Genghis Khan during the early 1200's and pushed into eastern Europe for a period in the mid-1200's. The empire reached its greatest extent under Kublai Khan in the late 1200's. The Mongols controlled most of India from the 1500's to the 1700's. The original Mongol homeland makes up what is now Mongolia.

WORLD BOOK map

ern Asia to the borders of eastern Europe. At various times it included China, Korea, Mongolia, Persia (now Iran), Turkestan, and Armenia. It also included parts of Burma (now Myanmar), Vietnam, Thailand, and Russia.

The Mongols, who eventually became known as the Tatars, were the most savage conquerors of history. But this vast empire helped increase contacts between peoples of different cultures. Migrations fostered these contacts and promoted trade. Roads were built to connect Russia and Persia with eastern Asia. Many Europeans came to China, and Chinese went to Russia and other parts of Europe. Printing and other Chinese inventions such as paper, gunpowder, and the compass may have been introduced to the West during Mongol times.

The Mongols originally consisted of loosely organized nomadic tribes in Mongolia, Manchuria, and Siberia. They lived in felt tents called *yurts,* and raised ponies, sheep, camels, oxen, and goats. They ate mainly meat and milk. Every Mongol man was a soldier and learned to ride and use a bow and arrow skillfully.

Early empire

Genghis Khan. In the late 1100's, Temüjin, a Mongol chieftain who later became known as Genghis Khan, rose to power as *khan.* He began to unify and organize the scattered Mongol and other nomadic tribes into a superior fighting force. Genghis Khan was shrewd, ruthless, ambitious, and a strict disciplinarian. After he became the undisputed master of Mongolia, and "lord of all the peoples dwelling in felt tents," he set out on a spectacular career of conquest.

Genghis Khan aimed to train the best-disciplined and most effective army of his time. As part of his military strategy, he formed an officer corps from Mongols who were trained in military tactics. These men were then stationed with various tribes as a training force. The Mongol tribes specialized in the art of siege. They used storming ladders and sandbags to fill in moats. Besiegers approached fortress walls under the protection of gigantic shields. Each tribe prepared a siege train, which consisted of special arms and equipment.

Invasions. Genghis Khan wanted to conquer China. He attacked first Xi Xia, a state along the northwestern border of China. Xi Xia represented the Chinese military pattern, with Chinese-trained armies and Chinese-built fortresses. In this campaign, Genghis Khan could evaluate his armies and train them for war against China.

The Mongols subdued Xi Xia, and then turned to North China. There the Ruzhen tribe of the Manchu people had established the Jin dynasty. Genghis Khan chose spring for his assault on China, so that his horses would have food when crossing the Gobi Desert. Warriors carried everything they needed on the march, and each rider had a spare horse. The hordes drove herds of cattle for food in the desert. But the Mongols were not able to subdue the Jin. The conquest of North China was not completed until 1234, after Genghis Khan's death.

In 1218, Genghis Khan broke off his attack on China and turned west toward central Asia and eastern Europe. His armies charged into the steppes of Russia and the Muslim lands, including Persia. They came within reach of Constantinople (now Istanbul) and destroyed much of Islamic-Arabic civilization.

All along their routes, the Mongol armies ruthlessly eliminated any resistance. They spread terror and destruction everywhere. When conquered territories resisted, the Mongols slaughtered the population of entire cities.

Genghis Khan died in 1227. The Mongols pushed into Europe under Ogotai, a son of Genghis Khan. In 1241, about 150,000 Mongol riders laid waste a large part of Hungary and Poland, threatening the civilization of west-

ern Europe. Ogotai died in the midst of this campaign. His death forced the Mongol generals to break off the campaign and return to Mongolia to elect a new khan.

Later empire

Kublai Khan, a grandson of Genghis Khan, completed the conquest of China in 1279, after attacking the Song dynasty in South China. Kublai Khan's Yuan dynasty lasted until 1368. He established the Mongol winter capital at Cambaluc (also spelled *Khanbalikh)*, the site of present-day Beijing. Further attempts to extend the Mongol Empire to Japan were unsuccessful. Mongol warriors fought unsuccessfully at sea and in the tropical climate of Southeast Asia.

The Mongols under Kublai Khan had a reputation for greater tolerance than that shown under earlier Mongol rulers. The Khan permitted the existence of various religions. He enlisted the services of Muslims, Christians, Buddhists, and Taoists. He supported Confucianism and Chinese political ideas, though he avoided having too many Chinese in high offices. In Persia and other Islamic lands, many Mongols adopted Muslim customs and the Muslim faith.

European contacts. Marco Polo was one of the most famous Europeans to travel to Asia at this time. His travel records contain much interesting information about the Mongols. His reports of beautiful Chinese cities and the riches of the country he called *Cathay* did much to arouse the interest of Europeans in exploring the possibilities of trade with Asia. Many Europeans, including Christopher Columbus, then sought to go to Asia by the sea route.

Kublai Khan expressed a desire to have more Christian missionaries sent to China. Dominican and Franciscan missionaries were welcomed by the Khan in Cambaluc. A Franciscan, John of Montecorvino, built a church in the capital and converted many people to Christianity.

Decline. The Mongol Empire did not last long, because it was too big and had no unity of culture. Actually, it began to disintegrate shortly after it reached its peak of expansion in the late 1200's. The Mongols were dauntless fighters but had little experience in administration. They relied upon other peoples to look after their affairs. They brought foreigners into China to avoid total reliance on the Chinese. The Mongols temporarily suspended the Chinese civil service system to allow these other peoples to assume positions.

Corrupt government and incompetent administration resulted in revolts in different parts of the empire. Even before the fall of the Yuan dynasty in China, the Mongols had lost control of many of their conquered lands. In some areas, they had never succeeded in firmly establishing their rule after their military conquests. Even at the peak of his power, Kublai Khan's authority did not extend to such distant places as Persia and Russia. The Mongols also lacked a firm hold in Southeast Asia.

Breakup. When Kublai Khan died, his empire broke up into several parts. These smaller empires were the Golden Horde on the steppes of southern Russia and the Balkans, the Mongolian-Chinese Yuan Empire, and the realm of the Ilkhans in western Asia. A revolution in China in the 1300's ended the Yuan dynasty and restored Chinese rule in the form of the Ming dynasty.

The great Timur (also called Tamerlane) combined some Mongol empires and extended his rule over much of Asia in the late 1300's. A descendant of Timur named Babur established a powerful Mongol state in India in 1526. Babur's realm was called the *Kingdom of the Great Mughals.* The term *Mughal* comes from the Persian word *mughul,* meaning a *Mongol.* A Mughal emperor, Shah Jahan, built the beautiful Taj Mahal in the early 1600's. The British destroyed the Mughal kingdom after it had begun to break up in the 1700's. Richard L. Davis

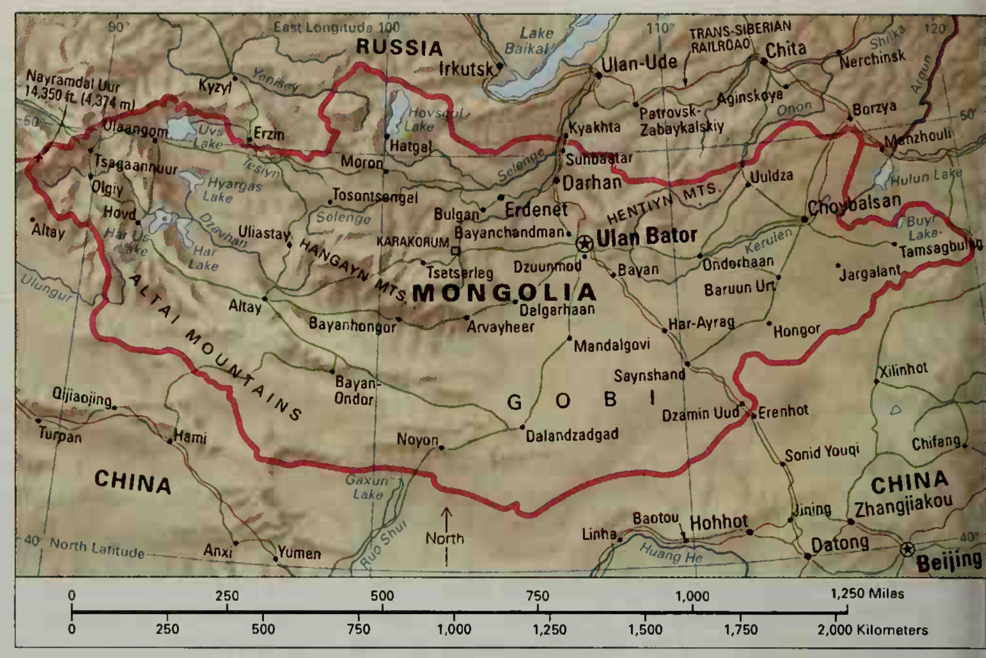
Shostal

A modern nomadic Mongolian family lives in tents similar to those of medieval times. The collapsible felt tents provide protection from the extreme heat and cold.

Medieval Tartar Huts and Waggons, drawing by Quinto Cenni. From *The Book of Sir Marco Polo* by Colonel Sir Henry Yule, London, published by John Murrey, 1903 (Newberry Library)



Mongols of the Middle Ages often carried their tents on large wooden wagons when moving. A team of many oxen drew the wagon. The driver stood in the entrance of the tent.

A modern nomadic Mongolian family lives in tents similar to those of medieval times. The collapsible felt tents provide protection from the extreme heat and cold.

Mongolia

WORLD BOOK maps

Mongolia, *mahng GOH lee uh,* is a country in east-central Asia. It lies between Russia and China. Ulan Bator is the capital and largest city.

Plateaus and towering mountain ranges cover much of Mongolia. The Gobi, a bleak desert area, blankets much of the southeastern part of the country. Mongolia's little rainfall occurs in a few summer storms.

Many Mongolians raise livestock for a living. But industry employs an increasing number of people.

Mongolia is the original home of an Asian people called *Mongols.* The Mongols built the largest land empire in history during the 1200's. They conquered an area from eastern Asia to eastern Europe. China ruled Mongolia from 1691 to 1911. Mongolia was then called *Outer Mongolia.* A Mongol region to the south, called *Inner Mongolia,* is still part of China.

Communists gained control of Mongolia's government in 1921. In 1924, they established the Mongolian People's Republic. Their party, the Mongolian People's Revolutionary Party (MPRP), became the country's only political party. In 1990, the MPRP gave up its monopoly on power, and many new parties were formed. Free elections were held in June of that year.

Government. Mongolia's president is elected by voters to a four-year term. The president is the head of the armed forces and nominates the prime minister, who carries out the day-to-day operations of government. The prime minister is usually the leader of the party or coalition with the most seats in the legislature. The prime minister nominates the ministers who make up the Cabinet.

Mongolia's people elect members of a national legislature that is called the State Great Hural. The members are elected to four-year terms. The 76-member State Great Hural makes decisions regarding domestic and foreign affairs. The legislature also *appoints* (approves) the prime minister and Cabinet.

For administrative and judicial purposes, the country is divided into 21 provinces, which are called *Aimags,* and the independent city of Ulan Bator, which is the capital of Mongolia.

The people. Nearly all the people of Mongolia are Mongols. Kazakhs make up the largest ethnic minority. Some Chinese and Russians also live in Mongolia.

The official language, Mongolian, has several dialects. Most of the people speak Khalkha Mongolian, which is the official dialect. Mongolian may be written in two ways. It is written in the Uyghur script, a traditional Mongolian alphabet borrowed centuries ago from the Uyghur Turks and written in vertical columns. It is also written in a special form of the Cyrillic alphabet, the alphabet of the Russian language.

Lamaism, which is a form of Buddhism, and Shamanism are the chief religions in Mongolia. The practice of religion was discouraged under Communist rule, but Mongolia's democratic government permits greater religious expression.

Many of Mongolia's people live on livestock farms. The farms are like huge ranches with small towns in the center. The central buildings include houses, offices, shops, and medical posts for the people and animals.

Few Mongolians still follow the traditional way of life

Facts in brief

Capital: Ulan Bator.
Official language: Mongolian.
Area: 604,829 mi² (1,566,500 km²). *Greatest distances*—east-west, 1,500 mi (2,414 km); north-south, 790 mi (1,271 km).
Population: *Estimated 2002 population*—2,455,000; density, 4 per mi² (2 per km²); distribution, 52 percent urban, 48 percent rural. *1989 census*—2,043,400.
Chief products: *Agriculture*—camels, cattle, goats, grain, horses, meat, milk, potatoes, sheep, vegetables. *Manufacturing and processing*—building materials, felt, processed foods, soap, textiles. *Mining*—coal, copper, molybdenum, petroleum.
Flag: Vertical stripes of red, blue, and red, with gold symbols on the left stripe. The flag was adopted in 1992. See **Flag** (picture: Flags of Asia and the Pacific).
Money: *Basic unit*—tugrik. One hundred möngö equal one tugrik.

of nomadic herders. Those who do, journey from place to place with their animals. They live in felt tents called *ger* or *yurts,* which help protect them from the intense heat and cold. The government is gradually settling the nomads on farms.

The Mongolian State University was founded in Ulan Bator in 1942. The country has teacher training colleges and technical schools where students study such subjects as agriculture, economics, and medicine.

Land. No part of Mongolia lies less than 1,700 feet (518 meters) above sea level. The Altai Mountains in western Mongolia rise to more than 14,000 feet (4,270 meters). A high plateau lies between the Altai Mountains and the Hangayn Mountains in central Mongolia. This plateau has many lakes. Uvs Lake, the largest, covers about 1,300 square miles (3,370 square kilometers). Dense forests cover the Hentiyn Mountains, northeast of Ulan Bator. Eastern Mongolia is a lower plateau of grassland. It becomes less fertile as it nears the Gobi, a bleak desert area that stretches from southeastern Mongolia into Inner Mongolia.

Climate. Mongolia has long, cold winters and short, hot summers. Temperatures ranging from −57 to 96 °F (−49 to 36 °C) have been recorded in Ulan Bator. Mongolia's coldest temperatures usually occur in the northern part of the country during the winter. Summer temperatures in the dry Gobi area in the south can be extremely high. Snowfall and rainfall in Mongolia are usually light. Heavy rains may occur in July and August. Violent earthquakes sometimes shake the country.

Economy. Under Communist rule, the state owned and operated most factories and farms in Mongolia. But since Communist rule ended, Mongolia has worked to reduce government control of industry. Livestock-raising is the backbone of the economy. Herders keep over 30 million animals, nearly half of them sheep. Other animals include camels, cattle, goats, and horses. Cattle make up about 35 percent of the country's exports, and wool about 40 percent. Mongolia also exports dairy products, furs, hides, and meat.

Manufacturing and construction are of major importance to the Mongolian economy. Building materials, furniture, glass and china, matches, processed foods, soap, tent frames and felts, and wool and woolen fabrics rank among the chief manufactured products. Mongolia has rich deposits of coal, copper, gold, iron, molybdenum, and petroleum.

Mongolia's main railroad connects Ulan Bator with Russia's Trans-Siberian railroad in the north and with Chinese railroads in the south. The country has about 47,000 miles (75,600 kilometers) of roads. Most of these are dirt roads. Mongolia and Russia trade goods over Hovsgol Lake and the Selenge River. Air service links Ulan Bator with other countries and with provincial capitals in Mongolia.

Mongolia's leading daily newspaper is *Odriin Toli (Daily Mirror).* The country also has a number of other newspapers and periodicals.

History. Various groups of Mongols were united under Genghis Khan in the early 1200's. Genghis Khan and his grandson Kublai Khan extended the Mongol Empire from Korea and China westward into Europe. The empire broke up in the late 1300's.

Mongol princes reunited Mongolia in the late 1500's and converted the people to Lamaism. In 1634, the Manchu rulers of Manchuria gained control of Inner Mongolia. The Manchus conquered China in 1644 and seized Outer Mongolia in 1691. Mongolia, like China, had little contact with other nations during the 1700's and the 1800's.

The Mongolians drove Chinese forces out of Outer Mongolia in 1911. They appointed a monk, called the *Living Buddha,* as ruler, and appealed to Russia for support. In 1913, China and Russia agreed to give Outer Mongolia control over its own affairs. Legally, Outer Mongolia remained Chinese territory. But, in fact, it came largely under the control of Russia. In 1920, during Russia's civil war, anti-Communist Russian troops occupied Outer Mongolia and ruled it through the Living Buddha. Mongolian and Russian Communists gained control of Outer Mongolia in 1921. They established the Mongolian People's Republic in 1924, after the Living Buddha died.

The Soviet Union was formed in 1922 under Russia's

On the Mongolian plains, wandering nomads live in collapsible tents called *ger* or *yurt, right.* The dwelling is made of layers of felt covered with canvas or hide. The enclosed pen, *foreground,* is for livestock. The government is gradually settling the nomads on farms.

leadership, and it existed until 1991. Mongolia supported the Soviet Union in the Soviet-Chinese dispute for leadership of the Communist world.

In the late 1980's, reforms resulted in more freedom for people in the Soviet Union and Communist countries of Eastern Europe. Influenced by these changes, people in Mongolia held demonstrations in early 1990 for more freedom. As a result, the country's ruling Communist party, the Mongolian People's Revolutionary Party (MPRP), gave up its monopoly on power. The country adopted a multiparty system and also began moving toward creating a free-enterprise economy.

In 1990, the MPRP won the legislative elections. In February 1992, a new democratic constitution went into effect. In elections held in June, the MPRP again won the majority of legislative seats. In 1996, a coalition of democratic parties, the Democratic Union Coalition, won the largest number of legislative seats. In legislative elections in 2000, the MPRP returned to power.

Mongolism. See **Down syndrome.**

Mongoose, *MAHNG goos,* is the name of several closely related small animals that live in Africa and southern Asia. They are related to the civet and the genet (see **Civet**). The common mongoose is about 16 inches (41 centimeters) long and has stiff, yellowish-gray hair that is grizzled with brownish-black. It has a fierce disposition but can be tamed.

The mongoose is best known for its ability to kill snakes. It is not immune to poison, but its swiftness allows it to seize and kill poisonous snakes such as the cobra. The mongoose also kills mice, rats, poultry, wild birds, and other small animals. It also eats birds' eggs.

The mongoose has been introduced into Jamaica, Cuba, Puerto Rico, Hawaii, and other parts of the world to destroy hordes of rats. However, in most cases, the mongooses have done more damage to native birds than to the rats. Mongooses cannot be brought into the United States without a permit from the Bureau of Sport Fisheries and Wildlife. A permit is granted only if the animal will be used in a zoological exhibit or for educational, medical, or scientific purposes. Gary A. Heidt

Scientific classification. The mongoose belongs to the family Herpestidae. There are about 17 genera. One genus, *Herpestes,* includes many Asiatic mongooses.

Monitor is the name of a group of about 30 kinds of lizards that live in the Solomon Islands, New Guinea, Australia, the East Indies, southern Asia, and Africa. In Australia, monitors are called *goannas.* A monitor has a long head and neck, and a narrow, deeply forked tongue. The body is usually black or brown with yellow bands, spots, or mottling. The legs are short and powerful, and the tail has a whiplike end. Monitors are usually at least 4 feet (1.2 meters) long. One, the *Komodo dragon,* is often 10 feet (3 meters) long. This species lives on the Lesser Sunda Islands of Indonesia.

When a monitor is cornered, it stands high on its legs and puffs up its body. This display makes the animal look larger than it is. A monitor may also defend itself by using its tail like a whip or by biting with its sharp teeth.

A monitor will eat almost any animal it can kill, including other reptiles, birds, mammals, insects, and crustaceans. Many monitors live near water, and they are all good swimmers and divers. When they swim, they hold their legs against their sides, driving forward by weaving their bodies and tails. Monitors lay eggs, and climb well. The best-known species are the Komodo dragon, the *Nile monitor* of Africa, and the *water monitor,* which lives from India to northern Australia. Laurie J. Vitt

Scientific classification. Monitors are in the monitor family, Varanidae. The scientific name for the Komodo dragon is *Varanus komodoensis;* the Nile monitor, *V. niloticus;* and the water monitor, *V. salvator.*

See also **Komodo dragon; Lizard** (picture).

Monitor and Merrimack fought a famous naval battle in the American Civil War (1861-1865). The two ships were called *ironclads* because they had been covered with iron. The battle, which ended with little damage to either the Union's *Monitor* or the Confederacy's *Merrimack,* focused worldwide attention on the importance of armor-plated ships. It was also the first sea battle in which the opposing ships were maneuvered entirely under steam power.

The *Merrimack,* or *Merrimac,* originally was a wooden frigate. Union troops sank it when they evacuated the Navy yard at Portsmouth, Va., after the war began in 1861. Confederate forces raised the ship and covered it with iron plates. They renamed it *Virginia,* though it is often referred to by its original name.

Peter Jackson, Bruce Coleman Ltd.

A mongoose prepares to eat a snake it has killed. The mongoose can fight snakes successfully because of its ability to dodge and pounce with lightning speed.

On March 8, 1862, the *Virginia* sank two Union ships at Hampton Roads, Virginia, and ran three others aground. The *Virginia* returned the next day, but it found a Union ironclad, the *Monitor,* waiting. The *Monitor* was built of iron as well as being ironclad. John Ericsson, a Swedish-American inventor, had designed this "cheese box on a raft" for the Union (see **Ericsson, John**).

The two ships battled for more than three hours. But their shells had little effect on either vessel, and the battle ended in a draw. Within the year, however, both ships were lost. The *Virginia* was destroyed to keep it from being captured by the Union. The *Monitor* filled with water and sank while being towed at sea in a storm.

In 1974, Duke University scientists announced that they had found the *Monitor* in the Atlantic Ocean. They reported that the ship lay about 16 miles (26 kilometers) south of Cape Hatteras, off the coast of North Carolina. In the late 1990's, naval archaeologists began to retrieve and restore portions of the *Monitor.* The gun turret was pulled up in 2002. Gabor S. Boritt

See also **Civil War** (First battle between ironclads).

Monitoring station receives and measures signals from radio transmitters. These signals come from such sources as AM and FM radio stations, television stations, radios in airplanes and ships, and amateur radios. Some countries use monitoring stations as "listening posts" to obtain information from other countries.

In the United States, the Federal Communications Commission (FCC) operates 13 monitoring stations. In Canada, the Department of Transport operates four stations. Both government agencies issue transmitter licenses and enforce operating regulations determined by national laws and international laws and treaties. Monitoring stations measure radio transmissions often to make certain the stations are operating under these regulations and the terms of their licenses.

The United States and Canada maintain many mobile monitoring vehicles. Long-range direction finders help locate sources of radio interference, unauthorized transmitters, and aircraft and ships in distress.

During World War II (1939-1945), the FCC operated as many as 102 monitoring stations, supported by automobiles with direction finders. This equipment was used to uncover radio transmitters operated by enemy agents.

Critically reviewed by the Federal Communications Commission

Monk is a man who has separated himself from ordinary ways of life to devote himself to his religion. Monks devote themselves to work, study, and prayer. To become a monk, a man must join a religious order. After a period of training, he is initiated into the order in a formal ceremony. As part of the initiation, a Christian monk takes vows of *poverty, chastity,* and *obedience,* promising to own no property, to refrain from sexual activity, and to obey superiors. See also **Buddhism** (The sangha); **Monasticism; Religious life.** Jill Rait

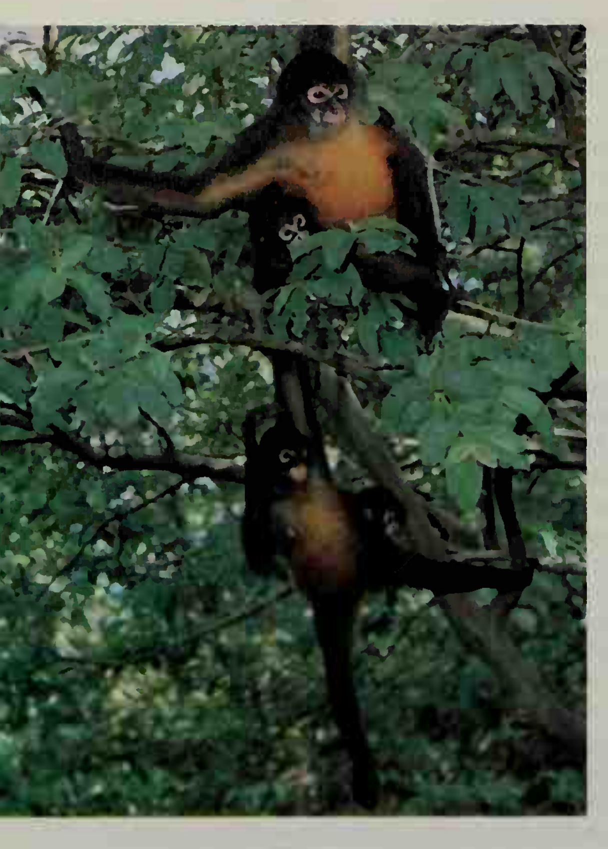
Monk, George. See Monck, George.

Monk, Thelonious, *thuh LOH nee uhs* (1917-1982), was an American composer, pianist, and bandleader. He gained recognition as one of the most adventurous and influential musicians in jazz. Monk's music is intensely rhythmic and often humorous. But his daring use of dissonance and his unique piano style made him a controversial figure. Many of his compositions, including "Round Midnight," "52nd Street Theme," "Epistrophy," and "Straight No Chaser," have become jazz standards.

Thelonious Sphere Monk was born on Oct. 10, 1917, in Rocky Mount, North Carolina, and grew up in New York City. He was closely associated with the bebop (or bop) movement in the early 1940's. In the early 1950's, Monk formed the first in a series of small jazz groups. He usually led quartets but occasionally formed an orchestra for concerts and recordings. The groups included several important tenor saxophonists, including Sonny Rollins, John Coltrane, and Charles Rouse. Monk died on Feb. 17, 1982. Gary Giddins

Monkey is one of many kinds of small, lively mammals that rank among the most intelligent animals. Scientists classify monkeys—together with human beings, apes, lemurs, and lorises—in the order Primates, the highest order of mammals. The intelligence of monkeys enables them to adapt to a broad range of environments. Because of the similarities between monkeys and human beings, scientists have used monkeys in research on human behavior and disease. For example, a blood substance called the *Rh factor* was discovered during experiments with the rhesus monkey (see **Rh factor**).

There are about 200 species of monkeys. Most of them live in tropical regions in Central and South America, Africa, and Asia. Most species live in forests, and some spend their entire life in the trees. Some African and Asian species live in *savannas* (grasslands with scattered trees) and spend most of their life on the ground. But even these monkeys sleep in trees—or on steep cliffs—for protection at night. All monkeys live together in various kinds of groups.



Monkeys vary greatly in size. The smallest species, the pygmy marmoset, measures only about 6 inches (15 centimeters) long, not including the tail. The mandrill, one of the largest species, may grow as long as 32 inches (81 centimeters), not including the tail.

Scientists classify monkeys into two major groups, New World and Old World monkeys. New World monkeys live in Central and South America, and Old World monkeys in Africa and Asia. The two groups differ in several ways. For example, New World monkeys have widely spaced nostrils. The nostrils of Old World monkeys are close together. Most New World monkeys have 36 teeth. Old World monkeys have 32 teeth, as do people. Some species of New World monkeys can grasp objects with their tail, but no Old World monkey can.

New World monkeys have a remarkable variety of sizes, shapes, and colors. Scientists divide them into two main groups: (1) marmosets and tamarins; and (2) all other New World species, including capuchins, douroucoulis, howlers, spider monkeys, squirrel monkeys, woolly monkeys, and woolly spider monkeys. All New World monkeys are *arboreal*—that is, they live in trees.

Old World monkeys include baboons, colobus monkeys, guenons, langurs, and macaques. Some Old World monkeys, including colobus monkeys and langurs, are *leaf-eating monkeys* and live mainly in trees. Many other Old World monkeys live on the ground. Among the monkeys that live on the ground, the males may be twice as large as the females. See the *Related articles* at the end of this article for a list of the monkeys about which *World Book* has separate articles.

Many people feel apes—bonobos, chimpanzees, gibbons, gorillas, and orangutans—are monkeys. But mon-

Monkeys live in many kinds of environments. Spider monkeys, *left,* dwell in forests of Central and South America. They swing and run swiftly among the tree branches. Baboons, *above,* roam African *savannas* (grasslands with scattered trees). They feed on the ground and sleep in caves or trees.

keys and apes differ in several ways. For example, apes are more intelligent than monkeys. Most monkeys have a tail, but none of the apes do. Monkeys are smaller than most apes. Apes are expert climbers. Monkeys generally run, jump, and leap among tree branches.

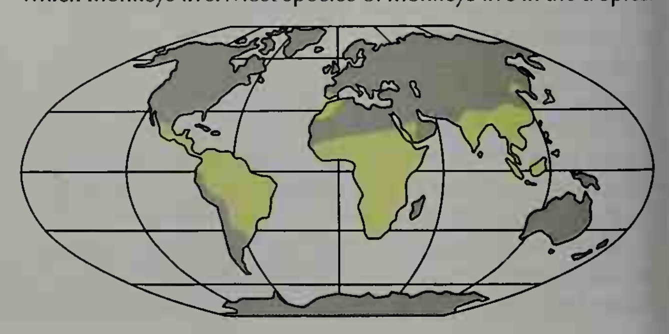
Human activities have greatly reduced the number of monkeys throughout the world. Some people hunt monkeys for food. Others catch them for pets. The clearing of land for agricultural, housing, and industrial developments has reduced the amount of living space available to monkeys. Some species of New World and Old World monkeys are threatened with extinction.

The body of a monkey

All monkeys, including those that live on the ground, are the descendants of monkeys that live in trees. As a result, all monkeys have a body primarily suited for living in and moving through trees. For example, monkeys have long arms and legs that help them climb, leap, and run. They also can use their hands and feet to grasp objects—including tree branches. Most species have a long tail that helps them keep their balance. Some New World monkeys can use their tail like a hand to grasp branches and food while moving through the trees.

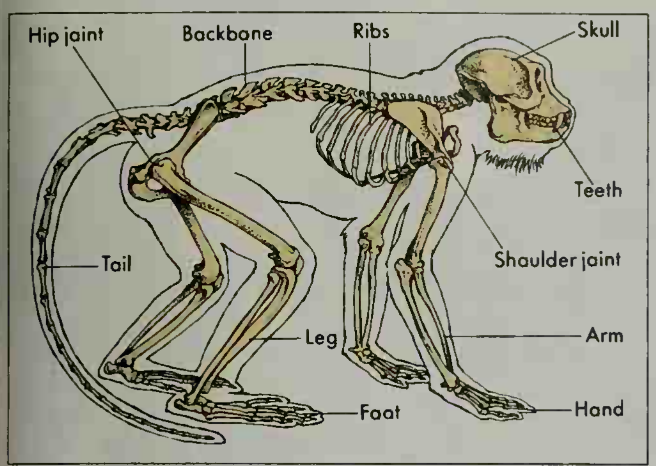
Head. Monkeys, unlike many other mammals, depend more on their eyes than their nose to gather information about their surroundings. They have large eyes that face forward. They can see in depth and distinguish colors. Their eyes help them judge distances and tell the size, shape, and ripeness of food.

Some monkeys, including baboons, mandrills, and sakis, have large, heavy jaws and eat grass and leaves. Smaller monkeys, such as marmosets and squirrel monkeys, have smaller, lighter jaws. They eat mostly fruit and insects. Many kinds of Old World monkeys have cheek pouches much like those of hamsters and squirrels. The pouches enable the monkeys to store food temporarily. No New World monkey has these pouches.



Arms and legs. Monkeys usually walk and run on all fours, either on tree branches or on the ground. Most species have legs that are slightly longer than their arms. Many kinds of monkeys can stand and even run on their legs, but only for a short time. Monkeys usually stand or run on their legs when they are carrying food, peering over high grass, or threatening enemies or members of the group.

Hands and feet. Old World monkeys have *opposable* thumbs—that is, the thumb can be placed opposite any of the other fingers. This enables a monkey to grasp small food items. Most kinds of New World monkeys have thumbs that are only partly opposable. Their thumbs also do not move so freely as those of Old World monkeys. Two kinds of New World monkeys—spider monkeys and woolly spider monkeys—have only tiny thumbs or no thumbs at all. Among Old World monkeys, colobus monkeys have no thumbs.



The feet of most monkeys are larger and more power-

Where monkeys live

The yellow areas of this map show the parts of the world in which monkeys live. Most species of monkeys live in the tropics.

A monkey's hands and feet both can grasp objects. The big toe of a monkey looks and moves like a thumb.

Shelly Grossman, Woodfin Camp, Inc.

A monkey's tail provides balance for running and jumping. A spider monkey can swing by its tail.

ful than their hands. All monkeys have five toes on each foot. The big toes look and function much like thumbs, giving the monkey an extra pair of grasping "hands." Marmosets and tamarins have claws on their fingers and toes, except for their big toes, which have a nail. All other kinds of monkeys have flat or flattish nails on all their fingers and toes.

Tail. Most monkeys that live on the ground have a shorter tail than do most that live in trees. Arboreal monkeys may have a tail longer than their body. They use their tail for balancing on tree branches. They also use it as an *air brake*—that is, to slow themselves down when they leap from branch to branch. Some New World monkeys, including howlers, spider monkeys, and woolly monkeys, can grasp objects with their tail. The tail of such monkeys has bare skin at the end. The tail of other monkeys is completely covered with hair.

The life of a monkey

Monkeys in captivity live longer than other animals of similar size. They also live longer than most other kinds of mammals, except apes and human beings. Capuchins may live 40 years. Baboons and some macaques may live 30 years. Life spans are shorter in the wild because of disease and other factors.

Food. Most kinds of monkeys eat almost anything they can find. The animals' diet usually includes birds and birds' eggs, flowers, frogs, fruit, grass, insects, leaves, lizards, nuts, and roots. Baboons may catch and eat such animals as newborn antelope.

Leaves make up about 40 percent of the food eaten by banded langurs and over 80 percent of the food of black and white colobus monkeys. All leaf-eating monkeys have sharp crests on their back teeth for shredding leaves. They also have large salivary glands and a large stomach that is divided into compartments. Such specialized structures help leaf-eating monkeys digest their coarse food. Unlike other Old World monkeys, leaf-eating monkeys do not have cheek pouches.

Young. Most kinds of monkeys give birth to one baby at a time. But marmosets and tamarins sometimes produce twins or even triplets. Scientists do not know the length of pregnancy of many species of monkeys, but the females of some species carry their young inside their bodies for about 4 $\frac{1}{2}$ months to about 8 months.

Most baby monkeys depend completely on their mother for food and security. They nurse on her milk for a few weeks to two years, depending on the species. A baby monkey hangs onto its mother almost from the moment of birth by grasping her fur. The mother carries the infant until it can travel safely on its own. At first, the infant clings to its mother's underside. Later, the young monkey rides on its mother's back. Among three kinds of New World monkeys—douroucoulis, marmosets, and titis—the father may carry the young on his back, giving them to the female for feeding.

Group life. All species of monkeys live together in social groups. New World monkey groups seldom consist of more than 20 members. Old World monkey groups usually have from 30 to 100 members. There are three kinds of monkey groups: (1) family groups, (2) multimale groups, and (3) one-male groups.

Family groups consist of an adult male, an adult female, and their young. At least three kinds of New World monkeys—sakis, titis, and owl monkeys—live in family groups. Three Old World species may also live in family groups. They are De Brazza's guenons, Mentawi Island langurs, and Hamlyn's owl-faced monkeys.

Multimale groups may consist of a number of adult males, about twice as many adult females, and their young. Most New World monkeys live in such groups, including capuchins, howlers, spider monkeys, squirrel monkeys, and marmosets. Many Old World monkeys, including langurs, macaques, and most baboons, also live in multimale groups.

One-male groups consist of one adult male, several

Vervets are among the commonest monkeys in Africa. Some may be found in city parks. They live in bands of from 6 to 20 members. Vervets feed and travel in trees and on the ground.

Oxford Scientific Films from Bruce Coleman Inc.

Rhesus monkeys, which are found in India, live in tightly organized groups. Like other ground-dwelling monkeys, they depend on group organization for defense.

adult females, and their young. Young adult males and females may also belong to the group. Certain species of Old World monkeys live in such groups. They include guenons, geladas, and hamadryas baboons.

In general, monkeys that live in trees have a looser social organization than do monkeys that live on the ground. For example, most guenons and mangabeys live in trees and form one-male groups of which the male is the leader. But he does not have strong leadership, and he has little control over the actions of other members of his group. The females in the group may mate with other males. Members of his group may leave, and new members may join. But monkeys that live on the ground, including most baboons, live in groups that are more tightly organized. A multimale baboon group is *closed*—that is, few members leave and few strangers join the group. Several dominant males control the group's movements, stop fights within the group, punish group members, and protect the group against enemies. The dominant males sometimes prevent other males in the group from mating with the females.

Scientists believe monkeys that live in trees have looser groups because these species are safer than those that live on the ground. The worst enemies of monkeys that live in trees are large eagles. Eagles kill adult and young monkeys with their powerful claws. Monkeys that live on the ground have many other enemies, including cheetahs, hyenas, jackals, leopards, and lions. These monkeys spend time in areas that have no nearby trees into which they can escape. As a result, they must be tightly organized under strong leaders so they can avoid danger or defend themselves.

Monkeys that live on the ground defend themselves chiefly by threatening their enemies. If a cheetah approaches a group of baboons, for example, the leaders of the group gather together to face their enemy. Each male baboon shows his long canine teeth and barks. If these actions do not frighten the cheetah away, the baboons may attack the animal.

Communication. Monkeys communicate with one another in various ways. For example, a male rhesus monkey threatens members of its group by staring, opening its mouth and showing its teeth, bobbing its head, and slapping the ground with its hands. *Social grooming* helps maintain friendly relations between baboons. In grooming, one baboon carefully cleans the fur of another. Both animals seem to find satisfaction in this activity. Baboons spend several hours a day grooming.

Randall L. Susman

Scientific classification. Marmosets and tamarins make up the marmoset family, Callitrichidae. All the other New World monkeys belong to the New World monkey family, Cebidae. Old World monkeys make up the Old World monkey family, Cercopithecidae.

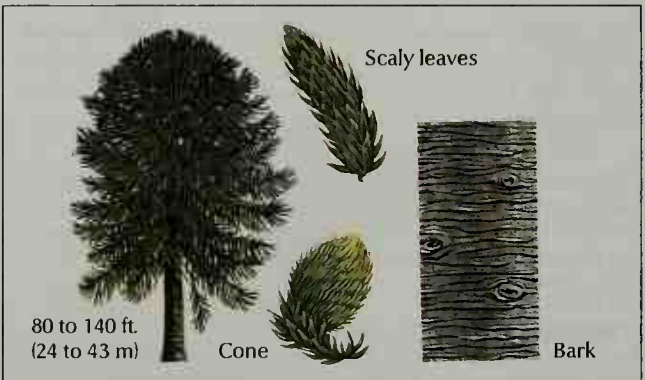
Monkey flower is the name of a large group of herbs and small shrubs. These plants have flowers with two

lips, an upper lip made up of two joined petals and a lower lip of three joined petals. The petals often have spots that make the flower look like a monkey's face.

There are many species of monkey flowers, which grow 6 to 36 inches (15 to 90 centimeters) high. They occur in South and North America, mostly on the Pacific Coast. Monkey flowers can be grown in gardens, garden borders, and greenhouses. W. Dennis Clark

Scientific classification. Monkey flowers belong to the figwort family, Scrophulariaceae. They make up the genus *Mimulus.*



Monkey puzzle tree, also known as the *Chile pine,* is a large evergreen tree with sharp, scaly leaves. These leaves densely cover the tree's spreading or drooping branches, which have a snakelike appearance. The monkey puzzle received its name because its leaves would make it difficult for even monkeys to climb.

Monkey puzzle trees may grow to 140 feet (43 meters) in height. They reproduce by means of cones. Male and female cones usually grow on separate trees. The male cones are long and slender, and the female cones are round or egg-shaped.

The monkey puzzle tree is native to the Andes Mountains in Chile and southwestern Argentina. People cultivate the tree in Europe and in the United States, especially the Pacific Northwest and the Southeast. The tree provides valuable timber and edible seeds, called *piñones* or *Chile nuts.* George Yatskievych

See also **Conifer.**

Scientific classification. The monkey puzzle tree belongs to the araucaria family, Araucariaceae. Its scientific name is *Araucaria araucana.*

Monmouth, *MAHN muhth,* **Duke of** (1649-1685), was an Englishman who led an unsuccessful rebellion against King James II. Monmouth was the illegitimate son of Charles II and a Welsh woman named Lucy Walter, and was a pretender to the throne of England.

Monmouth was born James Scott in Rotterdam, the Netherlands. His father became King Charles II in 1660 after Richard Cromwell lost power. Charles called Scott back to England and made him Duke of Monmouth.

In 1685, Charles II died and his brother James II became king. Monmouth claimed to be the legitimate heir to the throne, on the false grounds that his parents had married. After consulting with supporters in the Netherlands, he landed at Lyme Regis, near Weymouth, and issued a proclamation declaring James a usurper, tyrant, and murderer. He rallied about 4,000 men in southwestern England to overthrow James. But he was defeated at the Battle of Sedgemoor, near Taunton, and taken to the king. Before a court headed by Lord Jeffreys, he begged for his life. But he was imprisoned in the Tower of London and executed. Charles Carlton

Monnet, *moh NAY,* **Jean,** *zhahn* (1888-1979), a French businessman and statesman, led the movement to unify Western Europe in the 1950's and 1960's. He has been called the Father of the European Community, an important economic association that was incorporated into the European Union in 1993. Monnet proposed the European Coal and Steel Community in 1950 and was its president from 1952 to 1955. He set up the Action Committee for a United States of Europe and was its president from 1956 to 1975. He helped create the European Atomic Energy Community (Euratom) and the European Economic Community (Common Market), both formed in 1957. See **European Union.**

Monnet was born in Cognac. His career as an international financial adviser began when he helped organize Allied supply operations in World War I (1914-1918). From 1919 to 1923, he was deputy secretary general of the League of Nations. In World War II (1939-1945), he was an economic adviser to the American, French, and British governments and later became a member of the French provisional government. He created the Monnet Plan, a five-year recovery plan for France that was adopted in 1947. Monnet soon realized that France's recovery depended on a revived European economy. He also became convinced that the nations of Europe, acting separately, could no longer deal with Europe's economic and political problems. As a result, he began working to develop a United States of Europe.

Monnet received many honors. In 1963, he became one of the first Europeans to receive the Presidential Medal of Freedom, the highest civilian medal awarded by the United States. Alexander Sedgwick

Monoclonal antibody is a specialized type of protein molecule produced in the laboratory. Similar antibodies are produced naturally by the immune systems of animals and human beings when foreign substances, such as bacteria and viruses, invade the body. Antibodies can neutralize these substances by attaching to their *antigens.* Natural antibodies in blood are a mixture of many antibodies that react with many antigens, thus serving as the body's front-line defense against disease. But solutions of monoclonal antibodies act against a single specific antigen and can be made in large quantities. They have shown promise in medical research, including the detection and treatment of cancer.

A monoclonal antibody is produced in a test tube or culture dish by combining a tumor cell with a type of white blood cell called a *B cell.* The resulting hybrid cell, called a *hybridoma,* has properties of both the tumor cell and the B cell. Like the B cell, the hybridoma produces a specific antibody. Like the tumor cell, the hybridoma can grow and reproduce indefinitely in the laboratory. The hybridoma produces identical cells called *clones,* which in turn can survive in the laboratory and produce large quantities of monoclonal antibodies. Most monoclonal antibodies are produced from the B cells of laboratory animals, usually mice. Human monoclonal antibodies also have been developed. In one

technique of producing human monoclonal antibodies, *B cell* IR (immune response) genes are inserted into a bacterial cell, which can reproduce indefinitely.

Researchers use monoclonal antibodies to attach to and identify various cell types and in certain diagnostic tests for bacteria and viruses. For example, in some allergy detection tests, monoclonal antibodies are used to identify the substance that causes the allergy.

Monoclonal antibodies also show promise in fighting cancer. In some cases, these molecules can be designed to activate the body's immune system to attack tumors. Researchers are also investigating the use of monoclonal antibodies to deliver tiny doses of drugs or radiation to cancer cells without harming surrounding tissues. In addition, monoclonal antibodies carrying radiation may one day enable doctors to detect cancer when only a few malignant cells are present. Arlene R. Collins

Monocotyledon, *MAHN uh KAHT uh LEE duhn,* is a type of flowering plant that has one *cotyledon* (leafy structure within the plant's seed). The leaves of most monocotyledons have parallel veins. The flower parts usually grow in multiples of three. About 40,000 species of plants are monocotyledons, including bananas, pineapples, and corn. See also **Cotyledon.**

Monod, *maw NOH,* **Jacques Lucien,** *zhahk loo SYEHN* (1910-1976), a French biochemist, shared the 1965 Nobel Prize in physiology or medicine with François Jacob and Andre Lwoff. The scientists, all members of the Pasteur Institute in Paris, studied the action of genes in bacteria. They discovered a class of genes that controls other genes' activity. Radiation and some chemicals can cause these controlling genes to function improperly. If this happens, the other genes may go out of control and damage the cells. The discovery aided early research on cancer, a disease in which cells divide uncontrollably.

Monod was born in Paris on Feb. 10, 1910. He became head of the Pasteur Institute's cellular biochemistry department in 1954 and director of the Institute in 1971. He was also a professor at the Faculté des Sciences in Paris from 1959 to 1967 and at the Collège de France from 1967 to 1972. He died on May 31, 1976.

Monomer, *MAHN uh muhr,* is any molecule that can combine with identical molecules or certain other molecules to form a long, chainlike molecule called a *polymer.* All plastics and rubbers are made of polymers. Polymers also are used in such products as paints, waxes, glues, and lubricants. Heat, pressure, or chemical treatment may be used to cause monomers to combine. See also **Polymer.** Peter A. Rock

Monongahela River, *muh NAHN guh HEE luh,* provides river transportation between the rich coal fields of southwestern Pennsylvania and the steel factories at Pittsburgh. The river is formed where the Tygart and West Fork rivers meet in Marion County, West Virginia. It winds northeast across the boundary of Pennsylvania to the mouth of the Cheat River. It unites with the Allegheny at Pittsburgh to form the Ohio River. The Monongahela is 128 miles (206 kilometers) long. Boats can sail on the river in Pennsylvania. William C. Rense

Mononucleosis, *MAHN uh NOO klee OH sihs,* also called *infectious mononucleosis,* is an infectious disease. It is most commonly caused by the Epstein-Barr (EB) virus, one of the herpesviruses. The body's immune system fights EB virus by activating large numbers of lymphocytes, a type of white blood cell. The disease gets its name from the fact that these lymphocytes are *mononuclear* (single nucleus) cells.

Mononucleosis occurs most often in young adults but also strikes children and older people. Direct contact between people—kissing, for example—can spread the disease. The chief symptoms include chills, fever, sore throat, and fatigue. Lymph nodes, especially those in the neck, swell. Symptoms may also include rash, jaundice, an enlarged spleen, inflamed mouth and gums, and an enlarged liver. Most doctors recommend mild to complete bed rest for patients. The disease is rarely fatal, and most patients recover within three to six weeks.

Blood tests are used to diagnose mononucleosis. In a test used widely for many years, a sample of the patient's blood is mixed with sheep's blood. If the patient has mononucleosis, the sheep's blood cells stick together. Newer, more sophisticated tests identify mononucleosis by detecting specific antibodies formed in the blood to fight the EB virus. William J. Hermann, Jr.

Monopoly and competition are two kinds of business conditions. In a monopoly, one company or a cooperating group of companies controls the supply of a product or service for which there is no close substitute. In competition, a number of rival firms compete to sell similar goods or services to buyers.

The extent of rivalry between sellers, rather than the number of sellers in a market, determines whether there will be monopoly or competition. In some industries that have only a few sellers, those companies compete vigorously. Each firm tries to offer a better or cheaper product. Other industries have many sellers, but the companies act together as a monopoly would.

Kinds of monopoly and competition. Economists divide market conditions into four major categories: (1) monopoly, (2) pure competition, (3) monopolistic competition, and (4) oligopoly.

In a monopoly, a single firm is the only supplier of a product or service for which buyers cannot easily find a substitute. In some countries, public utilities, such as electric, gas, and water companies, are monopolies. A firm may be a monopoly because the market is too small to support others. A grocery store in a small isolated town may be a monopoly.

In pure competition, an industry consists of a large number of producers that sell nearly identical products. Pure competition is rare. In the United States, the sale of wheat and certain other agricultural products comes closest to this form of competition.

In monopolistic competition, rival firms sell different varieties of the same product or service. Each firm has a monopoly on its own variety of the product, but there are many close substitutes. For example, hundreds of manufacturers sell different styles of clothing.

In an oligopoly, a small number of companies dominate an industry. The policies of each company greatly influence those of the other firms because so few sellers are involved. In the United States, the automobile and computer industries are oligopolies.

Causes and effects of monopolies. A monopoly may develop for a number of reasons. For example, a

company may achieve the same volume of production more cheaply than its competitors because of greater efficiency. The more efficient firm may drive other producers out of business and achieve a monopoly.

In some industries, monopolies result from *entry barriers,* which are obstacles that prevent new companies from entering the market. Entry barriers include licenses and patents, which give a business the exclusive right to produce a particular product. A monopoly may also exist because a company controls the supply of a raw material required to make a product.

The reactions of rival firms to one another's policies play a key role in determining the degree of monopoly or competition. For example, a firm would hesitate to lower its prices if it thought its competitors would quickly match the cuts. All the rivals would have lower profits, and none would increase its share of sales.

Monopolies generally set prices higher than they would if there were competitive firms. Thus, monopolies generally make larger profits than competitive firms do. Unfortunately, a monopoly may sell a product of poor quality without suffering a loss in sales.

However, some economists believe monopolies may be useful. For example, a monopoly may be more efficient than a group of competing firms. Some experts also believe monopolies promote research and invention because large companies can sponsor more research programs with their additional profits. However, studies have shown that many companies do not increase research budgets after taking over an industry.

History. Some of the earliest monopolies were European shipping companies that operated during the Renaissance under royal charters. Kings, queens, and other rulers gave these companies exclusive rights to trade with people in Asia and other regions.

During the late 1800's and early 1900's, many business leaders in the United States tried to reduce competition. In some industries, many small firms merged to form large corporations. In other industries, firms formed monopolistic combinations called *trusts,* in which a group of managers controlled prices and production without a formal merger. Some trusts cut prices to force smaller firms out of business. The trusts then limited production and raised prices. Huge trusts monopolized many industries, including railroads, steel, and oil.

The abuse of monopolies and trusts led to a number of federal laws. The Sherman Antitrust Act of 1890 banned any trust or other combination that interfered with interstate or foreign trade. In 1911, the government used this act to break up the Standard Oil Company into more than 30 separate, competing firms. The Clayton Antitrust Act of 1914 made it illegal for corporations to group together under interlocking boards of directors. This law also prohibited several unfair business practices that large firms had used to eliminate smaller rivals. The Celler-Kefauver Act of 1950 tightened control over mergers that might reduce competition.

The U.S. Federal Trade Commission (FTC) and the Antitrust Division of the Department of Justice enforce antitrust laws. The FTC can order a company to stop unfair methods of competition. The Antitrust Division investigates and prosecutes businesses that violate antitrust regulations. In 1998, the Department of Justice charged Microsoft Corporation with abusing its monopoly in personal computer operating systems. In 2000, a U.S. district court judge ordered that Microsoft be split into two companies. Microsoft appealed the order, and in 2001 a federal appeals court reversed the decision to break up the company. The appeals court agreed, however, that Microsoft had abused its monopoly power. Microsoft then reached a proposed settlement with the Justice Department. Hearings on the proposed settlement began in a U.S. District Court in 2002.

The federal government and most state governments have special laws to control public utilities. Government regulation replaces competition in setting prices and standards of service for many of these companies. But in the late 1900's, the federal government took steps to allow increased competition among such utilities as telephone and electric power companies.

Monorail is a railroad that has only one rail. Monorail cars run along a rail above or below them. Cars that run above the track have either a gyroscopic device to balance them, or guide wheels that grip the side of the rail to keep the cars from falling over (see **Gyroscope**).

There are two types of suspended monorail systems. In the older type, the cars hang freely from wheels on a rail. The newer "split-rail" type suspends the cars from two rails close together in an enclosure. The enclosure ensures quieter operation and also keeps the track dry.

Monorail cars can be powered by electric motors,

Sally Wayland

gas turbines, or gasoline engines. Rubber wheels cut noise considerably. The smaller amount of friction in monorails allows greater speeds than two-rail lines with less operating cost.

The first monorail system, built in Wuppertal, Germany, in 1901, still carries passengers. Many cities have studied the possibility of building monorail systems that can be built quickly and can operate above a busy street. Ground supports for such systems require little space because monorails have only one rail.

The first monorail train in the United States began operating at Disneyland in Anaheim, California, in 1957. Other monorails are located at Seattle; Dallas; Lake Arrowhead, California; Pomona, California; New York City; and Lake Buena Vista, Florida. Tokyo, Japan, built an 8.2-mile (13.2-kilometer) monorail system for use during the 1964 Olympic Games there. Gus Welty

Monosodium glutamate (MSG) is a white, crystalline substance used to prepare and process many foods. MSG has a slight flavor of its own, but its chief effect is to bring out the tastes of such foods as meats, vegetables, seafood, soups, sauces, and casseroles.

MSG forms when sodium is added to an amino acid called *glutamic acid* (see Amino acid). Chemically, MSG is a sodium salt. However, it does not taste like table salt, which is sodium chloride, and it contains only one-third the sodium of table salt. Its taste is different from the four common categories of taste—salt, sour, sweet, and bitter. In 1908, the Japanese chemist Kikunae Ikeda discovered MSG's ability to improve the flavor of food.

Since the late 1960's, some people have reported suffering various discomforts due to eating MSG. However, studies of people who say they have experienced these discomforts have failed to prove that MSG caused them. Experiments with animals have shown that force-feeding or injecting MSG can damage sections of the immature brain. But studies in which MSG is added to the normal diet of animals have revealed no damage.

Two agencies of the United Nations, the Food and Agriculture Organization and the World Health Organization, jointly reviewed the safety of MSG. In 1988, they concluded that MSG is not a health hazard. In 1990, the European Community's Scientific Committee for Food reached the same conclusion. In the United States, the Food and Drug Administration lists MSG as "generally recognized as safe." Andrew G. Ebert

Monotreme. See Mammal (Reproduction; picture: Monotremes).

Monotype is a machine used to produce metal type for printing. It is noted for producing high-quality work. It has been used for printing fine books as well as catalogs, magazines, and other printed material. The Monotype has been replaced by *photocomposition* in most printing. Photocomposition is any of several methods of assembling images on photosensitive film or paper, or directly on a printing plate (see Photocomposition).

How the Monotype works. The Monotype machine consists of a *keyboard* and a *casting machine*. The keyboard is a typewriterlike composing machine. There are 225 keys on the board, and each key represents a separate letter or character. As a key is depressed, a corresponding code of small holes is punched in a paper ribbon or tape. A counter shows the space taken for each character. The operator knows from the counter exactly how much space has been used in each line and can *justify* the line—that is, make it the right length.

The casting machine is a miniature foundry that produces the type. The perforated tape from the keyboard is fed through the casting machine. The machine "reads" the code and selects the *matrix* (mold) corresponding to each coded character. Each character is then cast in metal as an individual unit. The cast types are delivered in the required order and justification for printing.

History. Printing with movable metal type was invented in the 1400's. Since then, printers have desired a method of type composition that would increase the speed, reduce the labor, and maintain the quality of hand composition. The American inventor Tolbert Lanston spent 13 years developing the Monotype machine to meet this demand. In 1887, he applied for a patent for his idea, though he did not have a model of the machine. John Sellers Bancroft, a machinist, developed the Monotype to virtually its final stage by 1899. It was widely used until the 1960's, when it was gradually replaced by photocomposition for most printing. J. C. McCracken

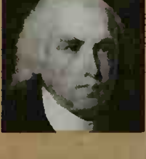
Monroe, Bill (1911-1996), was an American singer, musician, bandleader, and songwriter. He became known as the "father of bluegrass music." Bluegrass blends older forms of Southern folk and country music with elements of blues, gospel, and jazz. Bluegrass music takes its name from the Blue Grass Boys, a band Monroe formed in 1939. He played the mandolin and sang in a distinctive high tenor voice.

William Smith Monroe was born on Sept. 11, 1911, in Rosine, in rural western Kentucky. He was orphaned by the age of 16, and in 1929 he moved to the Chicago area where some of his older brothers and sisters lived. He began performing with his brother Charlie as the "Monroe Brothers," featuring close harmony vocals, supported by Charlie's rhythm guitar and Bill's mandolin solos.



In 1935, the brothers moved to the Southeast and gained great popularity with radio performances and personal appearances. The brothers split up in 1938. In 1939, Bill organized the Blue Grass Boys, named in honor of Kentucky, the Blue Grass State.

Monroe and the Blue Grass Boys first played at the Grand Ole Opry in 1939. The band's most popular early songs included "Mule Skinner Blues" (1940) and "Kentucky Waltz" (1945). Perhaps the most influential version of the band included Lester Flatt on guitar, Earl Scruggs on banjo, Chubby Wise on fiddle, and Howard Watts on bass. This band performed from 1946 to 1948. They recorded such bluegrass standards as "Blue Moon of Kentucky" (1946), "Molly and Tenbrooks" (1947), and "It's Mighty Dark to Travel" (1947). Later recordings included "Uncle Pen" (1950), "Raw Hide" (1951), and "On and On" (1954). Monroe died on Sept. 9, 1996. Paul F. Wells

Monroe, Harriet (1860-1936), was an American poet and editor. She founded *Poetry: A Magazine of Verse* in Chicago in 1912 and served as its editor until her death. Her magazine helped initiate and develop modern American poetry. Monroe also wrote poetry, including *You and I* (1914) and *The Difference* (1924). Her autobiography, *A Poet's Life: Seventy Years in a Changing World,* was published in 1938, after her death. She was born in Washington, D.C., on Dec. 23, 1860, and died on Sept. 26, 1936. Monroe, James (1758-1831), is best remembered for the Monroe Doctrine, proclaimed in 1823. This historic policy warned European countries not to interfere with the independent nations of the Western Hemisphere.

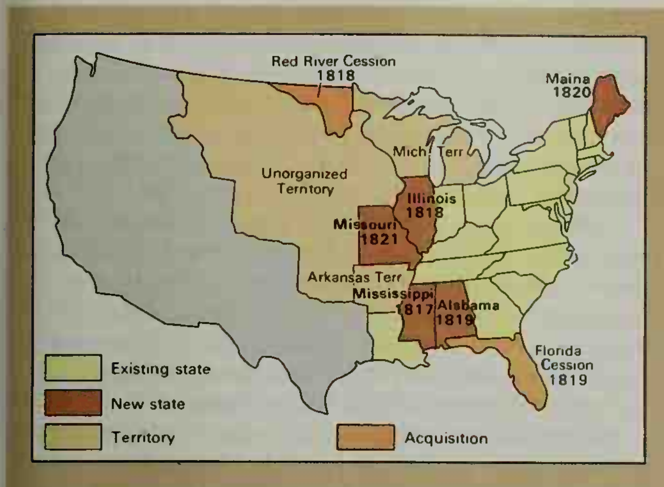
Monroe became President after more than 40 years of public service. He had fought in the Revolutionary War in America (1775-1783). During the first years after independence, he had served in the Virginia Assembly and in the Congress of the Confederation. He later became a United States senator; minister to France, Spain, and Britain; and governor of Virginia. During the War of 1812, he served as secretary of state and secretary of war at the same time.

In appearance and manner, Monroe resembled his fellow Virginian, George Washington. He was tall and rawboned, and had a military bearing. His gray-blue eyes invited confidence. Even John Quincy Adams, who criticized almost everyone, spoke well of Monroe.

At his inauguration, Monroe still wore his hair in the old-fashioned way, powdered and tied in a queue at the back. He favored suits of black broadcloth with knee breeches and buckles on the shoes. To the people, he represented the almost legendary heroism of the generation that led the country to independence.

As President, Monroe presided quietly during a period known as "the era of good feeling." He looked forward to America's glorious future, the outlines of which emerged rapidly during his presidency. The frontier was moving rapidly westward, and small cities sprang up west of the Mississippi River. Monroe sent General Andrew Jackson on a military expedition into Florida that resulted in the acquisition of Florida from Spain. Rapidly extending frontiers soon caused Americans to consider whether slavery should be permitted in the new territories. The Missouri Compromise "settled" this problem in the Louisiana Purchase area by setting definite limits to the extension of slavery there.



Early life

Boyhood. James Monroe was born in Westmoreland County, Virginia, on April 28, 1758. His father, Colonel Spence Monroe, came from a Scottish family that had settled in Virginia in the mid-1600's. The family of his mother, Elizabeth Jones Monroe, came from Wales, and also had lived in Virginia for many years. James was the eldest of four boys and a girl.

James studied at home with a tutor until he was 12 years old. Then his father sent him to the school of Parson Archibald Campbell. The boy had to leave home early in the morning and tramp through the forest to reach Campbell's school. He often carried a rifle and shot game on the way. At the age of 16, James entered the College of William and Mary. However, the stirring events of the Revolutionary War soon lured him into the army.

Soldier. Although only 18, Monroe was commissioned a lieutenant. He soon saw action, fighting at Harlem Heights and White Plains in New York in the fall of 1776. His superior officers praised Monroe for gallantry in the Battle of Trenton, N.J., where he was wounded in the shoulder. During the next two years, he fought at Brandywine and Germantown in Pennsylvania and Monmouth in New Jersey.

In 1778, Monroe was promoted to lieutenant colonel and sent to raise troops in Virginia. He failed in his mission, but it greatly influenced his future career. It brought him into contact with Thomas Jefferson, then governor of the state. Monroe began to study law under

Five states joined the Union during Monroe's term. The Red River and Florida cessions changed the boundaries of the United States.

The U.S. flag had 15 stars when Monroe took office in 1817. Nine stars were added during his term—five in 1818, one in 1819, two in 1820, and one in 1822.

The world of President Monroe

The Supreme Court of the United States established the doctrine of implied powers in 1819. The court ruled that the federal government has powers in addition to those specified in the Constitution. Implied powers are those necessary to carry out specified powers.

The first steamship crossing of the Atlantic Ocean was made by the American ship the *Savannah* in 1819.

Literature published during Monroe's administration included "Thanatopsis" (1817) by the American poet William Cullen Bryant; "A Visit from St. Nicholas" (1823) attributed to the American scholar Clement Moore; and *Persuasion* (1818) by the British novelist Jane Austen.

The first landing in Antarctica took place in 1821. The crew of an American seal-hunting ship went ashore at Hughes Bay, near the tip of the Antarctic Peninsula.

The first public high school in the United States opened in Boston in 1821.

The Santa Fe Trail, blazed by William Becknell in 1821, opened the southwestern United States to trade.

The Greek War of Independence against the Ottoman Empire began in 1821. The next year, Brazil declared its independence from Portugal.

The Latin American wars of independence ended in 1824 when the armies of the Venezuelan general Simón Bolívar defeated the Spaniards. This victory ended Spanish power in South America. In the same year, Mexico became a republic.

Jefferson's guidance, and became a political disciple and lifelong friend of his teacher.

Political and public career

Monroe began his public career in 1782, when he won a seat in the Virginia Assembly. In 1783, he was elected to the Congress of the Confederation, where he served three years (see **Congress of the Confederation**). Monroe did not favor a highly centralized government. But he supported moderate measures intended to let Congress establish tariffs. Monroe worked to give pioneers the right to ship goods down the Mississippi River through Spanish territory. He also helped Jefferson draft laws for the development of the West. Two hurried trips to the West had left Monroe unimpressed with its beauty or fertility. But he still believed the region would be important for the country's future growth.

State politics. In 1786, Monroe settled down to practice law in Fredericksburg, Virginia. But politics drew him like a magnet. He ran for the Virginia Assembly and won easily. He remained in the Assembly four years.

Important dates in Monroe's life

1758	(April 28) Born in Westmoreland County, Virginia.
1783	Elected to the Congress of the Confederation.
1786	(Feb. 16) Married Elizabeth Kortright.
1790	Elected to the United States Senate.
1794	Named minister to France.
1799	Elected governor of Virginia.
1811	Appointed secretary of state.
1814	Named secretary of war.
1816	Elected president of the United States.
1820	Reelected president.
1823	Proclaimed the Monroe Doctrine.
1831	(July 4) Died in New York City.

In 1788, Monroe served in the convention called by Virginia to ratify the United States Constitution. His distrust of a strong federal government aligned him with Patrick Henry and George Mason, who opposed the Constitution. But Monroe offered only moderate opposition, and he gracefully accepted ratification.

Monroe's family. In 1786, Monroe married 17-year-old Elizabeth Kortright (June 30, 1768-Sept. 23, 1830), the daughter of a New York City merchant. The couple had two daughters, Eliza Kortright and Maria Hester, and a son (probably named James Spence), but the boy died as an infant. Monroe's admiration for Jefferson

Library of Congress

Monroe's birthplace in Westmoreland County, Virginia, no longer exists. This drawing shows one artist's idea of how the house looked. Today, a historical marker stands near the site.

Elizabeth Kortright Monroe followed the President's wishes in observing strict social etiquette at the White House.

became so strong that in 1789 he moved to Charlottesville, Va. There he built Ash Lawn, not far from Jefferson's estate, Monticello.

U.S. senator. Monroe ran against James Madison for the first United States House of Representatives but lost. In 1790, the Virginia legislature elected him to fill a vacancy in the U.S. Senate. As a senator, Monroe aligned himself with Madison and with Jefferson, then secretary of state, in vigorous opposition to the Federalist program of Alexander Hamilton. Assisted by such leaders as Albert Gallatin and Aaron Burr, the three Virginians founded the Democratic-Republican Party. This party developed, some historians believe, into the modern Democratic Party (see **Democratic-Republican Party**).

Opposition to Washington. In 1794, President George Washington appointed Monroe minister to France. The President knew that Monroe opposed many administration policies, but he needed a diplomat who could improve relations with the French. He also knew that Monroe strongly admired France.

During talks in France, Monroe criticized the Jay Treaty between the United States and Britain as "the most shameful transaction I have ever known." Furious, Washington recalled Monroe in 1796. See **Jay Treaty**.

Upon his return, Monroe became involved in a bitter personal dispute with Hamilton. The quarrel resulted from the publication of materials that slandered Hamilton. Monroe was blamed but denied responsibility. Hamilton eventually dropped his charges.

Diplomat under Jefferson. In 1799, Monroe was elected governor of Virginia. In this post, he played an important part in preserving democratic processes during the tense years following passage of the Alien and Sedition Acts, which made it a crime to criticize the President or Congress falsely and maliciously. In 1803, President Thomas Jefferson sent Monroe to Paris to help Robert R. Livingston negotiate the purchase of New Orleans. By the time Monroe reached France, Napoleon had offered the astonished Livingston the entire Louisiana Territory. Monroe urged Livingston to accept the offer without waiting to consult Jefferson, and they arranged for the treaty. See **Louisiana Purchase**.

Jefferson was pleased with Monroe's initiative and sent him to Madrid to help Charles Pinckney purchase the Floridas from Spain. They failed, but Jefferson still had confidence in Monroe. The President named him minister to Britain. In 1806, however, Monroe helped conclude a trade treaty that was so unsatisfactory that Jefferson refused to submit it to the Senate.

Monroe felt his usefulness in London had ended and returned home in 1807. He became a reluctant candidate for the nomination to succeed Jefferson as President. But Madison won the nomination and the presidency. Monroe served in the Virginia Assembly until he again was elected governor in 1811.

Secretary of state. Monroe resigned as governor after about three months to accept President Madison's appointment as secretary of state. At that time, U.S. relations with Britain and France were strained. The British navy had been taking American sailors of British birth and *impressing* (forcing) them back into British service. In addition, Britain and France had set up naval blockades against each other that greatly interfered with U.S. shipping. Monroe soon concluded that these problems could not be resolved peacefully.

At the beginning of the War of 1812, Monroe was eager to take command of the Army. But Madison convinced him to stay in the Cabinet. Secretary of War John Armstrong was forced to resign in 1814 because of neglect of duty during the burning of Washington, D.C. Madison asked Monroe to become secretary of war while continuing as secretary of state. Monroe held both offices for the rest of the war. After he took over the War Department, American armies won several brilliant victories. These triumphs greatly increased Monroe's popularity. See **War of 1812**.

In 1816, while still secretary of state, Monroe was elected President of the United States. He received 183 electoral votes to 34 for Senator Rufus King of New York, the Federalist candidate. For votes by states, see **Electoral College** (table). Monroe's running mate was Governor Daniel D. Tompkins of New York.

Monroe's Administration (1817-1825)

The years of Monroe's presidency are generally known as "the era of good feeling." The Federalist Party gradually disappeared after the election of 1816, and most people supported the Democratic-Republican Party. The country prospered because of fast-growing industries and settlement of the West. A depression in 1818-1819 caused only a temporary setback.

"The American System" was the chief issue of Monroe's first term. House Speaker Henry Clay of Kentucky advanced this plan. The American System proposed to strengthen the nation in two ways: (1) construction of new roads and canals to open the West, and (2) enactment of a protective tariff to encourage Northern manufacturers and develop home markets.

Monroe distrusted the American System because he

doubted that the federal government had the power for these activities. Monroe studied the program during a $3\frac{1}{2}$-month tour of the North and West. But this trip did not change his "settled conviction" that Congress did not have the power to build roads and canals.

Clay continued his fight and finally won Congress over to his side. In 1822, Monroe vetoed a bill providing for federal administration of toll gates on the Cumberland Road. He urged a constitutional amendment to give Congress the power to promote internal improvements. In 1824, Monroe signed the Survey Act, which planned improvements in the future.

Clay had more success in pushing through the protective tariff, the second part of his American System. Congress had already raised tariff rates in 1816, and it further increased the duty on iron in 1818. In 1824, Congress raised tariff rates in general.

Life in the White House. The British had burned the White House during the War of 1812, and the mansion had not been rebuilt when Monroe took office. The new President maintained his residence on I Street, near 20th Street, for nine months. On New Year's Day, 1818, President and Mrs. Monroe held a public reception marking the reopening of the White House.

Monroe decided to follow strict etiquette in the White House. Partly because of ill health, Mrs. Monroe received only visitors to whom she had sent invitations. She refused to pay calls, sending her elder daughter, Eliza Hay, in her place. Soon all Washington buzzed about the "snobbish" Mrs. Monroe.

As time passed, the public realized that Mrs. Monroe had followed the President's wishes in establishing protocol. During Monroe's second term, her Wednesday receptions became popular. The visit of the Marquis de Lafayette on New Year's Day, 1825, added a touch of splendor to the last months of Monroe's term.

Beginnings of sectionalism. In 1818, Missouri applied for admission to the Union as a slave state. The House of Representatives aroused anger in the South by passing a bill to admit Missouri with the provision that no more slaves could be brought into the state. The Senate defeated this provision, and Congress eventually agreed on a plan known as the Missouri Compromise. Under the plan, Congress admitted Maine to the Union as a free state and authorized Missouri to form a constitution so it could then apply for statehood. Congress permitted slavery in Missouri but banned it from the rest of the Louisiana Purchase region north of the southern boundary of Missouri. Monroe avoided interfering with these debates. But he said he would not sign a bill placing any special restraints on Missouri's admission to the Union. See Missouri Compromise.

War with the Seminole. Since the War of 1812, Americans in Georgia had been harassed by bands of Indians in Spanish Florida, partly because the Americans were not honoring their treaties with the Indians. In 1817, fighting broke out between the Seminole Indians and settlers in southern Georgia. Monroe ordered Major General Andrew Jackson to attack the Indians. Jackson chased them into the Everglades of Florida. Then he captured Pensacola, Spanish Florida's capital.

Jackson's easy conquest convinced the Spanish that they could not defend Florida. In 1819, they agreed to give Florida to the United States in return for the cancel-

Quotations from Monroe

The following quotations come from some of Monroe's speeches and writings.

National Honor is National property of the highest value.
First Inaugural Address, March 4, 1817

The American continents . . . are henceforth not to be considered as subjects for future colonization by any European powers.
Annual Message to Congress, Dec. 2, 1823

We owe it, therefore, to candor, and to the amicable relations existing between the United States and those powers to declare that we should consider any attempt on their part to extend their system to any portion of this hemisphere as dangerous to our peace and safety. With the existing colonies or dependencies of any European power we . . . shall not interfere. But with the Government . . . we could not view any interposition for the purpose of oppressing them, or controlling in any other manner their destiny, by any European power, in any other light than as the manifestation of an unfriendly disposition toward the United States.
Annual Message to Congress, Dec. 2, 1823

In a government founded on the sovereignty of the people the education of youth is an object of the first importance. In such a government knowledge should be diffused throughout the whole society, and for that purpose the means of acquiring it made not only practicable but easy to every citizen. . . .
Speech to the Virginia Legislature, Dec. 7, 1801

The Monroe Doctrine warned European nations against interfering in the affairs of countries in the Western Hemisphere. This picture shows Monroe, *standing*, explaining the doctrine to his Cabinet. Monroe proclaimed the doctrine to guarantee the independence of Latin America.

Culver

lation of $5 million in American claims against Spain.

Diplomacy. Monroe's Administration marked one of the most brilliant periods in American diplomacy. The Rush-Bagot Agreement, signed with Britain in 1817, limited naval forces on the Great Lakes. In 1818, Britain agreed to the 49th parallel as the boundary between the United States and Canada from Lake of the Woods on the Minnesota-Ontario border as far west as the Rocky Mountains. The British also consented to joint occupation of the Oregon region. American diplomats persuaded Spain to give up its claims to Oregon in 1819, and the Russians agreed to a similar pact in 1824.

Reelection. In the election of 1820, Monroe was unopposed. He received every vote cast in the Electoral College but one. William Plumer, an elector from New Hampshire, cast his vote for John Quincy Adams.

The Monroe Doctrine. During the Napoleonic Wars, the Spaniards had become deeply involved in European affairs and took little interest in their American colonies. Most of the colonies took advantage of this situation and declared independence from Spain. The Latin-American revolutions aroused great sympathy in the United States. As early as 1817, Henry Clay had begun a campaign for recognition of these new countries. Over the period of time from 1822 to 1824, Monroe finally recognized their independence. In December 1823, the President proclaimed the historic Monroe Doctrine in a message to Congress. This doctrine has remained a basic American policy ever since.

The era of good feeling ended before Monroe finished his second term. Unlike the situation which followed the retirement of Jefferson and Madison, there was no outstanding figure who was the overwhelming choice to become the next President. Four men fought for the office. None won a majority of the votes, and the House of Representatives chose John Quincy Adams. See **Adams, John Quincy** (Election of 1824).

Later years

Monroe retired to Oak Hill, his estate near Leesburg, Va. He served for five years as a regent of the University of Virginia. In 1829, he became presiding officer of the Virginia Constitutional Convention. His wife died on Sept. 23, 1830, and was buried at Oak Hill. Long public service had left Monroe a poor man, and he was too old to resume his law practice. Late in 1830, his financial distress forced him to move to New York City to live with his daughter. Monroe died there on July 4, 1831. In 1858, his remains were moved to Hollywood Cemetery in Richmond, Virginia. His law office in Fredericksburg has been preserved as a memorial.

Monroe, Marilyn (1926-1962), was an American motion-picture actress whose great beauty made her a world-famous sex symbol. But in spite of her success in films, Monroe had a tragic life. She died at the age of 36 from an overdose of sleeping pills. Since her death, she has become one of the most written-about film stars in history.

Monroe's real name was either Norma Jean Baker or Norma Jean Mortenson. She was born in Los Angeles and made her film debut in 1948 in *Dangerous Years.* Monroe soon won attention with small roles in *The Asphalt Jungle* (1950) and *All About Eve* (1950). Her most successful dramatic roles were in *Bus Stop* (1956) and *The Misfits* (1961). She appeared as a comedienne in *Gentlemen Prefer Blondes* (1953), *The Seven-Year Itch* (1955), and *Some Like It Hot* (1959). Monroe appeared in 28 films. She was married to former baseball star Joe DiMaggio in 1954, and they were divorced that same year. Monroe was married to playwright Arthur Miller from 1956 to 1961.

Monroe Doctrine was set forth by President James Monroe in a message that he delivered to the Congress of the United States on Dec. 2, 1823. The doctrine supported the independent nations of the Western Hemisphere against European interference "for the purpose of oppressing them, or controlling in any other manner their destiny." The doctrine said also that the American continents were "henceforth not to be considered as subjects for future colonization by any European powers." This statement meant that the United States would not allow new colonies to be created in the Americas, nor would it permit existing colonies to extend their boundaries.

Origins. The Monroe Doctrine grew out of conditions in Europe as well as in America. The three leading absolute monarchies of Europe were Russia, Austria, and Prussia. They had pledged themselves to "put an end to the system of representative government, in whatever country it may exist in Europe." The United States feared that these three powers (sometimes called the *Holy Alliance*) might also try to suppress representative government in the Americas.

During and after the Napoleonic Wars, most of the Spanish colonies in America had taken advantage of unsettled conditions in Europe to break away from the mother country. As they won independence, these colonies formed themselves into republics with constitutions much like that of the United States. Only Brazil chose to keep the monarchy form of government when it declared its independence from Portugal.

After Napoleon's downfall in 1815, the monarchy was restored in Spain, and it seemed possible that the Holy Alliance might try to restore Spain's colonies as well. The French monarchy, which had followed the policy of the Holy Alliance to the point of actually suppressing a democratic revolution in Spain, was also suspected of intending to help Spain regain its former American possessions. A rumor that France was on the point of doing so spread over Europe during 1823.

This threat disturbed not only the United States, but Britain as well. As free republics, the Spanish-American nations traded with Britain. If they became colonies again, whether of Spain or of France, their trade with Britain would certainly be cut down. Britain had steadily opposed the doctrine of the Holy Alliance and had few allies in Europe. George Canning, the British foreign minister, proposed to Richard Rush, the American minister in London, that Britain and the United States issue a joint warning against aggression by European countries in the Americas.

President Monroe was at first inclined to accept the British offer. Former Presidents Thomas Jefferson and James Madison strongly favored the idea. With Britain "on our side," Jefferson argued, "we need not fear the whole world." But Monroe's secretary of state, John Quincy Adams, said that the United States should not "come in as a cock-boat in the wake of the British man-of-war." He urged that the United States alone issue the warning. He said that the British would use their sea power to prevent European intervention in America whether they had an agreement with the United States or not. Thus the United States would have all the advantages of joint action without entering into what amounted to an alliance with Britain. Moreover, a strictly American declaration would clearly apply to Britain as well as to other European countries.

Monroe finally decided to follow Adams's advice and proclaimed the Monroe Doctrine. He used practically the same words in the doctrine that Adams had used when he first proposed it to him.

Results. Until the late 1800's, Europe's respect for the rights of the smaller American nations rested less upon the Monroe Doctrine than upon fear of the British Navy. A possible exception to this rule occurred in the 1860's, shortly after the American Civil War, while the wartime Army and Navy of the United States were still strong. During those years, the attitude of the American government encouraged Emperor Napoleon III to give up an attempt to set up a European kingdom in Mexico. It was not until the 1880's, when the United States began to enlarge its new Navy of modern steel ships, that the United States again had enough power to enforce the Monroe Doctrine. Britain and other countries generally ignored the doctrine until the 1890's.

The Monroe Doctrine also served to express U.S. interest in increasing its trade with the other countries of the Western Hemisphere. However, Europe continued to get the larger share of Latin American trade, most of which went to Britain.

In some ways, the Monroe Doctrine strained relations between the United States and the Latin American countries. The nations that the doctrine supposedly protected actually resented the way the United States assumed su-

periority over them. They also feared "The Colossus of the North" more than they feared any European nation.

The Monroe Doctrine in action. In the 1800's, the doctrine was seldom invoked. President James Polk referred to it in 1845 during a dispute with the United Kingdom over Oregon. Secretary of State William Seward acted partly on the basis of the doctrine when he denounced French intervention in Mexico in the 1860's. President Grover Cleveland used it when he threatened to take strong action against the British in 1895 if they would not arbitrate their dispute with Venezuela.

The Roosevelt Corollary. In the early 1900's, President Theodore Roosevelt gave new meaning to the Monroe Doctrine. He claimed that wrongdoing by the smaller American nations might tempt European countries to intervene in those nations, either to collect debts or to defend the lives and property of Europeans. According to Roosevelt, the Monroe Doctrine required the United States to prevent European intervention by intervening itself. Under this "big stick" policy, the United States sent troops into the Dominican Republic in 1905, into Nicaragua in 1912, and into Haiti in 1915.

In general, President Woodrow Wilson continued Roosevelt's policy. He promised that the United States would "never again seek one additional foot of territory by conquest." But as president, he interfered in a revolution in Mexico and tried unsuccessfully to gain support for intervention from other Latin American countries.

The "Good Neighbor Policy." After World War I ended in 1918, the United States worked to improve relations with Latin America. Herbert Hoover made a good-will tour of South America before he became U.S. president in 1929. During his administration, he moved away from the policy of intervention in Latin America.

Hoover's successor as president was Franklin D. Roosevelt. Roosevelt's policy toward the Latin American countries became known as the "Good Neighbor Policy." Under it, Roosevelt abandoned the practice of intervention and tried to expand trade with Latin America. He also sought Latin American cooperation in defending North and South America from countries located outside the Western Hemisphere.

During the Hoover and Roosevelt administrations, the United States gradually withdrew its forces from the smaller American countries it had occupied and gave up the special privileges it had claimed. By a series of trade agreements, it cut down high tariff barriers that had done much to keep the Americas apart. Conferences on inter-American affairs were held at Montevideo, Uruguay, in 1933; at Buenos Aires, Argentina, in 1936; at Lima, Peru, in 1938; and at Havana, Cuba, in 1940.

During World War II (1939-1945), fear of Nazi aggression brought the American republics somewhat closer. The republics met at Rio de Janeiro, Brazil, in 1942; at Mexico City, Mexico, in 1945; and at Petropolis, Brazil, in 1947. They set up the Organization of American States at a meeting in Bogotá, Colombia, in 1948.

The Monroe Doctrine and isolationism. Some people have confused the Monroe Doctrine with the policy of *isolationism,* or staying out of international political and economic affairs. The original statement of the Monroe Doctrine did affirm an earlier U.S. policy of isolation from Europe. That policy had been set forth by President George Washington in his Farewell Address of 1796. However, the Monroe Doctrine implied that the United States would play a more active role in the Western Hemisphere. Mark T. Gilderhus

Monrovia is Liberia's capital, as well as its educational and cultural center. The American Colonization Society founded the city in 1822 as a place to resettle freed slaves from the United States.

Monsoon, *mahn SOON,* is a seasonal wind that blows over the northern part of the Indian Ocean, especially the Arabian Sea, and over most of the surrounding land areas. The monsoon blows continually from the southwest from June through September. It blows from the northeast from December through March.

Monsoons are generated by the difference in the heating and cooling of air over land and sea. During the summer, radiant energy from the sun heats land surfaces far more than it does sea surfaces. The strongly heated air over the land rises and is replaced by a southwesterly wind carrying warm, moist air from the Indian Ocean. Water vapor in the rising air condenses and forms clouds and rain. This process releases large amounts of heat, which helps drive monsoons.

In winter, the land is cooled much more than the sea. The cool air over the land sinks and spreads out to the sea as a dry northeasterly wind.

The southwesterly monsoon brings heavy rains to southern and southeastern Asia, including Bangladesh, India, Myanmar, and Thailand. The strength of the

southwesterly monsoon—and the time in June that it begins—affects agriculture in southern Asia. Abnormal monsoons can destroy a region's crops and livestock and disrupt its economy. Monsoons also blow over the coasts of northern Australia, eastern Asia, parts of Africa and the southwestern United States. Richard A. Dirks

Mont Blanc, *mawn BLAHN* or *mahnt BLAHNGK,* is the highest mountain in the Alps. Mont Blanc is often called the *monarch of mountains.* Its name is French for *white mountain.* Mont Blanc rises 15,771 feet (4,807 meters) on the border between France, Italy, and Switzerland. The base of the mountain is a huge mass of granite that extends into all three countries. Its highest peak is in southern France. Mont Blanc is about 30 miles (48 kilometers) long and 10 miles (16 kilometers) wide. Thick woods and swift streams cover its lower slopes. But above 8,000 feet (2,400 meters), there is always a thick blanket of snow. Mont Blanc has several large glaciers. Its most famous glacier is Mer de Glace (Sea of Ice). A scientific laboratory was built on Mont Blanc in 1893.

Jacques Balmat, a French glass cutter, and Michel Paccard, a French physician, first climbed Mont Blanc in 1786. Today, it is easily climbed, and it is a resort center. People can ride up 6,287 feet (1,916 meters) to Mer de Glace on a cog railway. For those who prefer to climb, there are shelters to aid them in their 50- to 60-hour journey. The world's highest aerial tramway goes up Aiguille du Midi, a lower peak of Mont Blanc. In 1965, the Mont Blanc tunnel, linking France and Italy, was opened for auto traffic. Howell C. Lloyd

See also Alps (map); Mountain (diagram: Major mountains).

Mont-Saint-Michel, *mawn san mee SHEHL,* is a large, steep granite rock that lies off the coast of Normandy, a region in northern France. For location, see France (terrain map). Mont-St.-Michel rises 260 feet (80 meters) and covers 16 acres (6.5 hectares). An *abbey* (home of monks) stands at the top of Mont-St.-Michel, and a small village lies at the base. Mont-St.-Michel's scenery and architecture make it a major tourist attraction.

Mont-St.-Michel was important in religious practices of the Celts, a people who inhabited the area in ancient times. In 708, a local bishop built a church on top of the rock. The present abbey replaced the church in 966. Later building programs added such features as a chapel and tower. William M. Reddy

See also France (picture: Mont-St.-Michel).

Montagnais Indians, *MAHN tuh NYAY,* are a tribe that once hunted and fished throughout the southern Labrador Peninsula in Canada. The name *Montagnais* comes from a French word meaning *mountain people.* The tribe received this name from French explorers, probably because of the rugged terrain of their land.

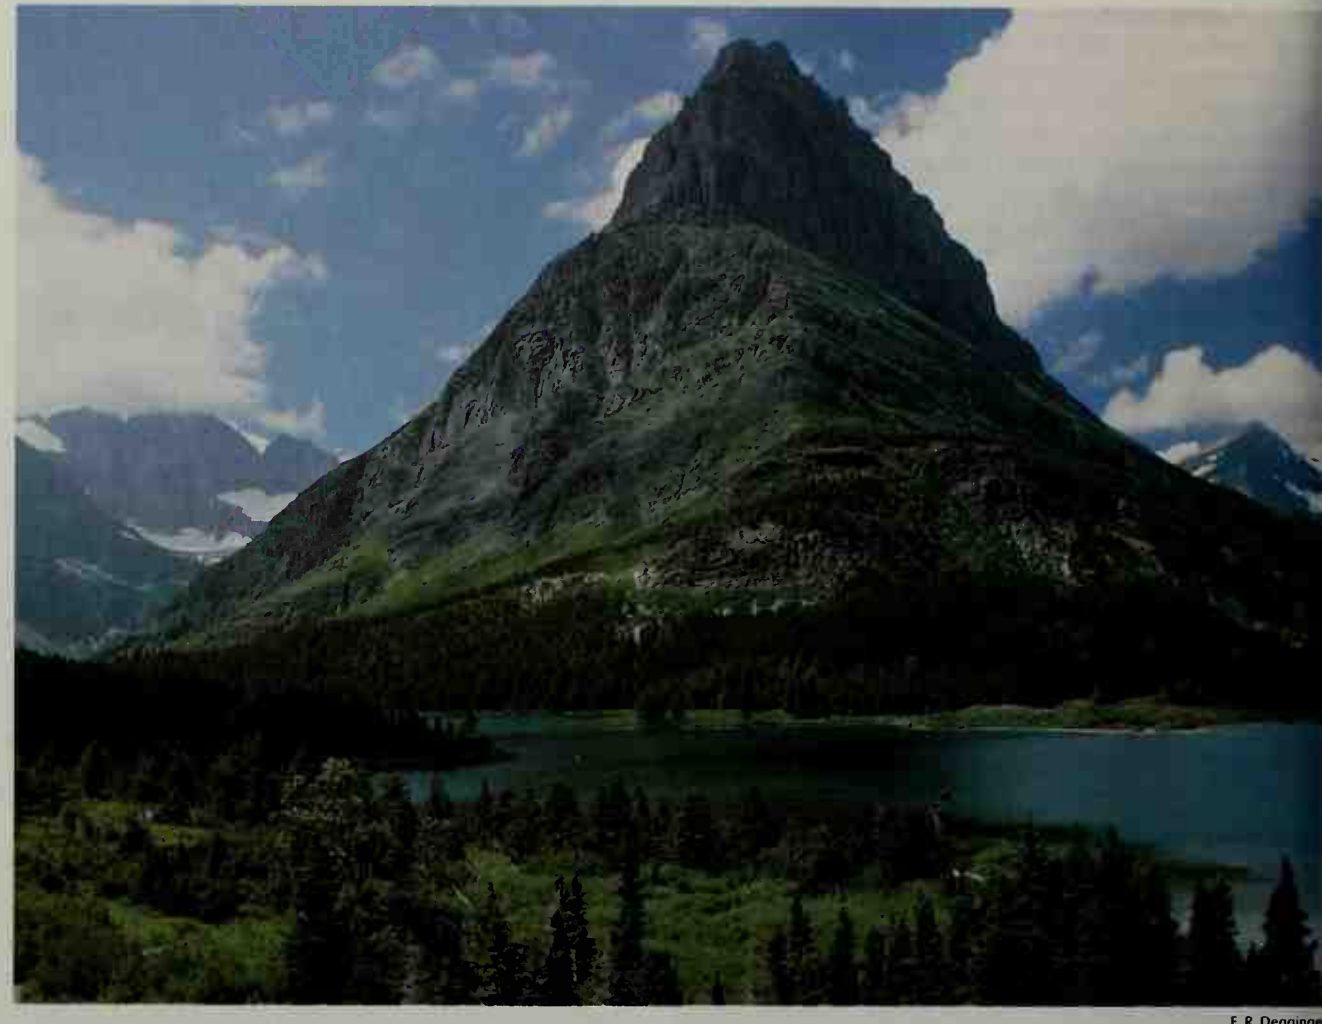
The Montagnais were nomads who traveled in small bands consisting of about 50 to 100 related people. They lived almost completely by hunting and fishing because the growing season was too short for farming.

Montagnais bands moved as the seasons changed in search of game. They spent the winter in the forests hunting moose and caribou, using toboggans and snowshoes for travel. They lived in lodges constructed partly underground and covered with snow or earth. In the summer, they camped along the St. Lawrence River and other waterways, and traveled by canoe to fish for salmon and eel. Their summer homes were cone-shaped tents covered with skins or bark.

In 1603, the French explorer Samuel de Champlain became the first European to encounter the Montagnais. The tribe soon became partners of the French in the fur trade. The Montagnais maintained a trading center on the St. Lawrence from which they controlled the trade between neighboring tribes and the French. During the 1600's, many Montagnais died in battle with the Iroquois. Guns obtained from European traders enabled the Montagnais to kill more game. By the early 1700's, however, large animals had become scarce, and many Montagnais died of starvation or disease.

Today, many Montagnais continue to rely on hunting and fishing to make a living. About 7,000 Montagnais live on nine reserves in Quebec. James A. Tuck

Montaigne, *mahn TAYN,* **Michel Eyquem de,** *mee SHEHL eh KEHM duh* (1533-1592), a French writer, is considered by many the creator of the personal essay. Writers up to the present time have imitated his informal, conversational style. Montaigne's essays reveal his independent mind and sound judgment, his charm and wit, and his wealth of experience in life and literature. The most original aspect of the essays was Montaigne's goal to make himself the subject matter of his writings. He first began publishing his essays in 1580, adding to them as life and experience provided him with new insights and understanding. He wrote a total of 107 essays, including the long "Apology for Raymond Sebond" with its famous skeptical motto, "What do I know?"



Montaigne was born on Feb. 28, 1533, in his family's castle near Bordeaux. He studied law, and he became a minor legal official in 1554. Montaigne retired in 1570 to devote himself to writing. From 1581 to 1585, he served as mayor of Bordeaux. He died on Sept. 13, 1592. Montaigne immortalized his friendship with the French writer Étienne de La Boétie in the essay "Of Friendship."

Mary B. McKinley

Montale, *mohn TAH lay,* **Eugenio,** *ay oo JAYN yoh* (1896-1981), was an Italian lyric poet and literary critic. He received the 1975 Nobel Prize in literature.

Montale was born in Genoa on Oct. 12, 1896. He spent much of his youth in Monterosso, a small town on the shore of the Ligurian Sea. This rugged coastline setting inspired many of the images of his early verse. His first book of poetry was *Cuttlefish Bones* (1925). The poems stress the themes of the modern individual's loss of faith, the impossibility of human happiness, and poetry's powerlessness to transform reality. The collection *The Occasions* (1939) further developed these themes. An English translation of his early verse was published in 1999 after his death as *Collected Poems: 1920-1954.* Later volumes of poems include *The Storm and Other Poems* (1956), and *Notebook of Four Years* (1977, published in English as *It Depends: A Poet's Notebook).*

Montale wrote a number of autobiographical short stories published in *The Butterfly of Dinard* (1956). Many of his essays were collected in *Act of Faith* (1966) and *Away from Home* (1968). Montale also became known for his masterful Italian translations of English-language poets. He died on Sept. 12, 1981. Richard H. Lansing

E. R. Degginger

Glacier National Park, located in northwestern Montana, has many steep, rugged peaks such as Grinnell Point, *above.* The park also has more than 50 glaciers and about 250 lakes. The Rocky Mountains cover the western two-fifths of the state. To the east lie the Great Plains.

Montana *The Treasure State*

Montana is the fourth largest state of the United States. Only Alaska, Texas, and California have larger areas than Montana. Western Montana is a land of tall, rugged mountains. There, miners dig deep into the earth to tap the state's vast deposits of copper, gold, and silver. Eastern Montana is a land of broad plains. The view from these vast, open plains has earned Montana a nickname, *The Big Sky Country.* On the plains, herds of cattle graze on the prairie grasses, wheat grows in the fertile soil, and wells bring up petroleum from deep under the ground. Eastern Montana also has the largest coal reserves in the United States. Billings is the largest city in Montana.

The name *Montana* comes from a Spanish word meaning *mountainous.* Early travelers, who saw the sun glistening on the lofty, snow-capped peaks, called the area the *Land of Shining Mountains.* These mountains contained a wealth of gold and silver, which gave the state another nickname, the *Treasure State.* Glacier National Park has mountain peaks so steep and remote that they have never been climbed.

Early Montana was Indian country. But gold was discovered in Montana in 1862, and great numbers of eager prospectors rushed to the area. Mining camps sprang up overnight, and wealth came to the territory. But the gold also brought problems. Outlaws spread terror in the mining camps until groups of citizens called *vigilantes* took the law into their own hands. The vigilantes hanged many outlaws and drove others away. Montana was the scene of another struggle—the Indians' last efforts to keep their land. The last stand of Lieutenant Colonel George A. Custer was fought in Montana. In addition, the final battles of the Nez Perce War were fought in the state.

The mountains, the battlefields, the old gold camps, and the vast, lonely distances of Montana still make a visitor feel close to the American frontier. In the state's capital, Helena, the main street is called Last Chance Gulch. The name comes from a gold camp that once stood on that site. Even today, when a basement is dug for a building in Helena, the digging sometimes produces gold dust.

Interesting facts about Montana

WORLD BOOK illustrations by Kevin Chadwick

Grasshopper Glacier, near Cooke City, is named for the swarms of grasshoppers that became trapped in its ice long ago and can still be seen.

Benton Lake National Wildlife Refuge, in north-central Montana, is one of the most productive waterfowl nesting sites in the United States. About 25,000 waterfowl and 10,000 shore birds are raised there annually.

Bibles were first placed in hotel rooms in October 1908 in Iron Mountain (now Superior). The Gideons placed them in the Superior Hotel.

One of the richest deposits of gold ever found in the United States was discovered at Alder Gulch (now Virginia City) in 1863. Within a year, about 10,000 people had settled within 10 miles (16 kilometers) of the site.

Gideon Bibles

Giant Springs

Giant Springs, in Great Falls, is among the largest springs in the world. Each day, about 390 million gallons (1.5 billion liters) of water gush out of the ground there.

More gem sapphires are found in Montana than in any other state.

Stu White

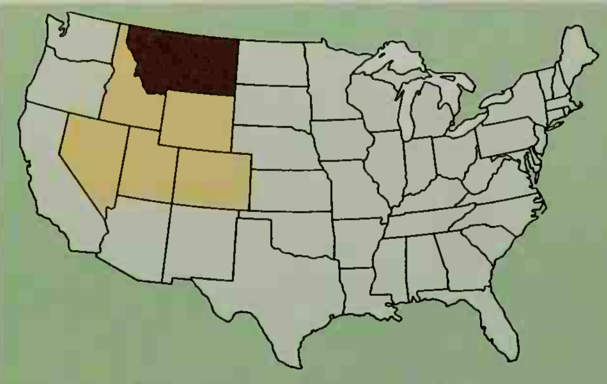
Great Falls is Montana's second largest city, and one of only two metropolitan areas in the state. It was named for nearby falls of the Missouri River.

Montana Travel Promotion

A petroleum refinery in Billings processes Montana oil. Montana has valuable reserves of petroleum and coal.

Montana in brief

Symbols of Montana

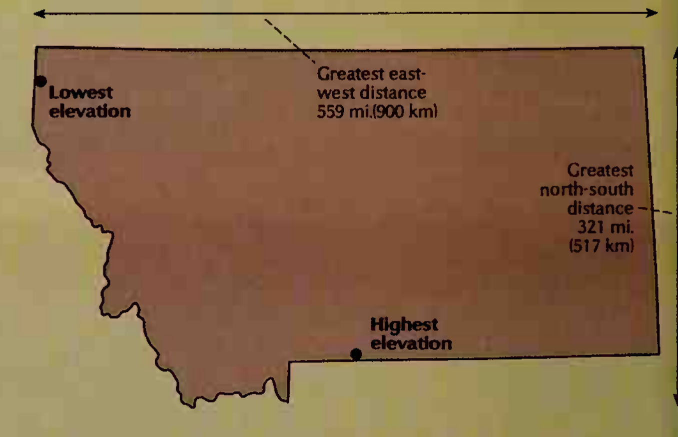


The state flag, adopted in 1905, displays an adaptation of the state seal within a field of blue. The word *MONTANA* was added to the flag in 1981. On the state seal, adopted in 1893, the mountains and the Great Falls of the Missouri River symbolize Montana's vast natural resources. The plow stands for agriculture, and the pick and shovel represent mining. The state motto is on a ribbon.

State flag

State seal

Montana (brown) ranks fourth in size among all the states and first in size among the Rocky Mountain States (yellow).



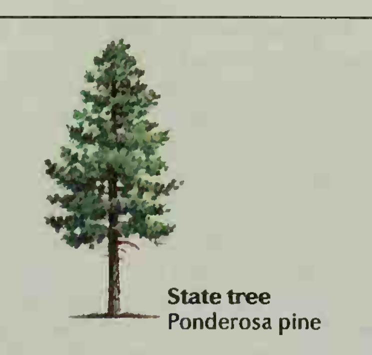
General information

Statehood: Nov. 8, 1889, the 41st state.
State abbreviations: Mont. (traditional); MT (postal).
State motto: *Oro y Plata* (Gold and Silver).
State song: "Montana." Words by Charles C. Cohen; music by Joseph E. Howard.

The State Capitol is in Helena, Montana's capital since 1875. Earlier capitals were Bannack (1864-1865) and Virginia City (1865-1875).

Land and climate

Area: 147,047 sq. mi. (380,849 km²), including 1,490 sq. mi. (3,859 km²) of inland water.
Elevation: *Highest*—Granite Peak, 12,799 ft. (3,901 m) above sea level. *Lowest*—1,800 ft. (549 m) above sea level along the Kootenai River in Lincoln County.
Record high temperature: 117°F (47°C) at Glendive on July 20, 1893, and at Medicine Lake on July 5, 1937.
Record low temperature: −70°F (−57°C) at Rogers Pass on Jan. 20, 1954.
Average July temperature: 68°F (20°C).
Average January temperature: 18°F (−8°C).
Average yearly precipitation: 15 in. (38 cm).



Important dates

- **1803** — Eastern Montana became U.S. territory through the Louisiana Purchase.
- **1805-1806** — Lewis and Clark explored parts of Montana on their journey to and from the Pacific.
- **1846** — Northwestern Montana became U.S. territory through the Oregon treaty with England.
- **1862** — Gold was discovered on Grasshopper Creek.
- **1889** — Montana became the 41st state on Nov. 8.

Economy

Chief products

Agriculture: beef cattle, wheat, barley, hay.
Manufacturing: refined petroleum, wood products, machinery, food products.
Mining: coal, copper, gold, petroleum.

Gross state product

Value of goods and services produced in 1998: $19,862,000,000. *Services* include community, business, and personal services; finance; government; trade; and transportation, communication, and utilities. *Industry* includes construction, manufacturing, and mining. *Agriculture* includes agriculture, fishing, and forestry.

Source: U.S. Bureau of Economic Analysis.

Government

State government

Governor: 4-year term
State senators: 50; 4-year terms
State representatives: 100; 2-year terms
Counties: 56

Federal government

United States senators: 2
United States representatives: 1
Electoral votes: 3

Sources of information

For information about tourism, write to: Department of Commerce, Travel Montana, 1424 9th Avenue, P.O. Box 200533, Helena, MT 59620. The Web site at www.visitmt.com also provides information.

For information on the economy, write to Department of Commerce, Census and Economic Information Center, 1424 9th Avenue, P.O. Box 200505, Helena, MT 59620.

The state's official Web site at www.state.mt.us also provides a gateway to much information on Montana's economy, government, and history.

1910 [T]he U.S. Congress established [G]lacier National Park.

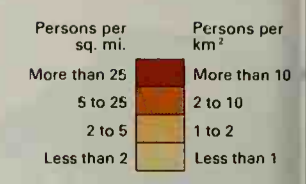
1940 Fort Peck Dam was completed.

1951 The first oil wells in the Montana section of the Williston Basin started production.

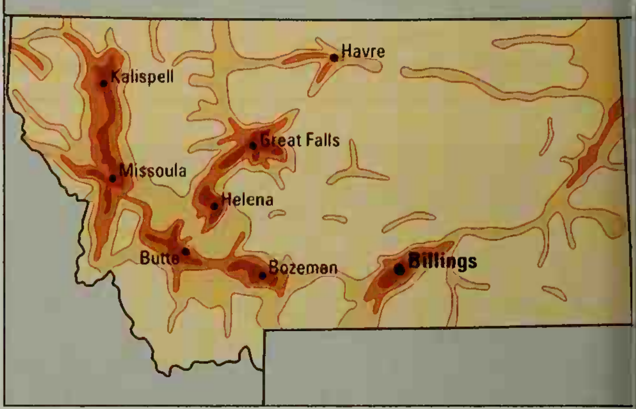
1973 A new state constitution went into effect.

1984 Libby Dam hydroelectric project was completed.

People



Population. The 2000 United States census reported that Montana had 902,195 people. The state's population had increased 13 percent over the 1990 census figure, 799,065. According to the 2000 census, Montana ranks 44th in population among the 50 states. Montana has about 56,000 American Indians, most of whom live on reservations. They make up about 6 percent of the state's population.

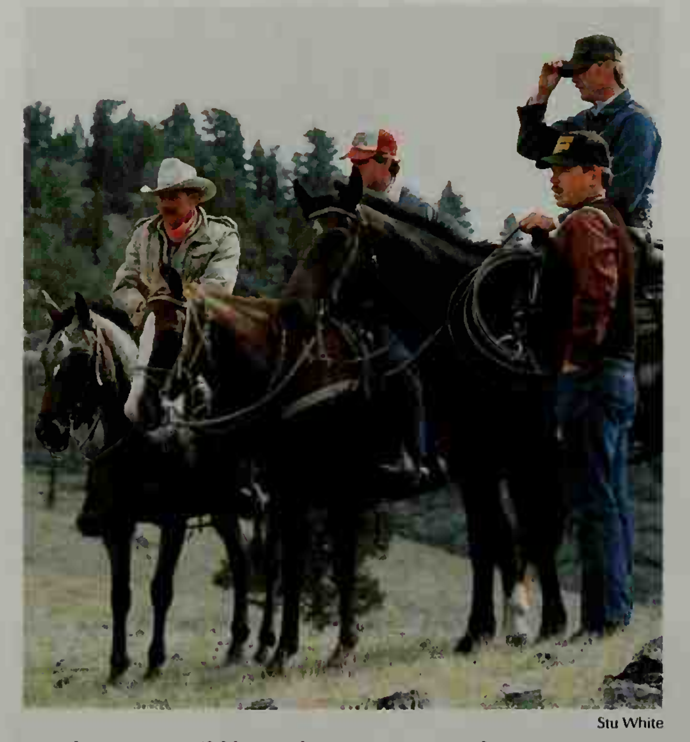


About one-third of Montana's people live in metropolitan areas (see **Metropolitan area**). Billings, Great Falls, and Missoula are the only cities of more than 55,000 people, and they are the only metropolitan areas in the state. Montana has four other cities with a population of more than 10,000. These cities, in order of population, are Butte, Bozeman, Helena, and Kalispell.

Most of Montana's cities began as mining towns, or as centers of trade for farm and ranch areas. Butte grew from a mining camp. So did Helena, the state capital. Missoula developed as an agricultural trade center.

Population density

More than half of the people of Montana live in urban areas. The most densely populated areas are in the west and the south. Billings is the largest city.



WORLD BOOK map; based on U.S. Census Bureau data.

Universities and colleges

This table lists the universities and colleges in Montana that grant bachelor's or advanced degrees and are accredited by the Northwest Association of Schools and Colleges.

Name	Mailing address
Carroll College	Helena
Great Falls, University of	Great Falls
Montana, University of	Missoula
Montana Tech of the University of Montana	Butte
Montana State University	*
Rocky Mountain College	Billings
Salish Kootenai College	Pablo
Western Montana College	Dillon

*Campuses at Billings, Bozeman, and Havre.

Stu White

Cowboys on a wild horse hunt near Cascade try to capture wild horses for use on a ranch. Some of Montana's farmland is used for livestock grazing. Many of the state's farms cover as many as 7,000 acres (2,800 hectares).

Schools. Montana's first schools were started in mining camps in the early 1860's. They had private teachers who charged tuition. The Roman Catholic Church set up a boarding school for Indians in the Flathead Valley in 1864. The Legislature provided for free public schools in 1893 and for county high schools in 1897.

Today, Montana's public schools are supervised by an elected superintendent of public instruction and a Board of Public Education that is appointed by the governor. The superintendent serves a four-year term. Each county and most school districts have a superintendent of schools. Montana's two largest universities are Montana State University, with campuses in Billings, Bozeman, and Havre; and the University of Montana, in Missoula. For the number of students and teachers in the state, see **Education** (table).

Libraries. The library of the state historical society in Helena features the world's largest collection of materials on the history of the Montana region. The libraries of the University of Montana and Montana State University also have good collections of regional materials. The library at the Montana State University campus in Billings has large collections of material on famous Montanans and Yellowstone National Park. Montana has about 110 public libraries.

Museums. The Montana Historical Society in Helena features exhibits on the development of the state and a fine collection of paintings and sculpture by famous cowboy artist Charles M. Russell. Great Falls also has a Russell museum. The Museum of the Rockies in Bozeman has exhibits of the geology, fossils, archaeology, and history of the Rocky Mountains. The Museum of the Plains Indians and Craft Center in Browning has collections of historic and contemporary arts of the Plains Indians. The World Museum of Mining is in Butte. Other museums are at Big Hole National Battlefield, Wisdom; and Little Bighorn Battlefield National Monument.

Visitor's guide

Few states equal Montana in attractions for outdoor recreation. People from all over the world travel to Montana to fish, camp, and hike. Montana's mountains and lakes are perfect for winter activities, such as ice fishing, snowshoeing, snowmobiling, and skiing. Lovers of the outdoors also enjoy the state's national parks, national forests, dude ranches, ski lodges, summer resorts, and other attractions. Montana's wide-open spaces are home to a wide variety of birds and animals that are no longer found in many other states. Trips to old ghost towns, Indian battle sites, and points along the Lewis and Clark trail in Montana interest history enthusiasts.

Montana's Western heritage is reflected in the rodeos and Indian ceremonies that are held throughout the state. Almost every Montana town has a rodeo. Nationally ranked riders compete for large cash prizes in some rodeos. In others, hometown cowboys and cowgirls show their skill. Rodeo owners buy wild horses in a May Bucking Horse Sale in Miles City. Indians on Montana's reservations perform colorful dances and ceremonies.

Places to visit

Following are brief descriptions of some of Montana's most interesting places to visit.

Bannack, near Dillon, has been preserved to look as it did in 1865, when it was one of the nation's richest gold camps.

Beartooth Highway leads from Red Lodge to Yellowstone Park. It is open from June to September. Motorists on this route see spectacular mountain views as they wind over the Beartooth Plateau, which is 11,000 feet (3,350 meters) high.

Flathead Lake recreation area, in northwestern Montana, offers boating, fishing, and swimming. The lake is the largest naturally occurring freshwater lake in the United States west of the Mississippi River.

Fort Peck Dam, near Glasgow, is one of the world's largest dams. It forms Fort Peck Lake, which is popular for boating, fishing, camping, and sightseeing.

Glacier National Park, in northwestern Montana, includes a large area of majestic mountain scenery. It has more than 50 glaciers that lie on the mountain slopes. Several of its rugged peaks have never been climbed. See **Glacier National Park.**

Helena has many historical points of interest. Attractions include the State Capitol, St. Helena's Cathedral, Last Chance Gulch, and the original governor's mansion.

Lewis and Clark National Historic Trail Interpretive Center, in Great Falls, focuses on the relations between Native Americans and the Lewis and Clark exploration group.

Medicine Rocks, near Ekalaka, lie in the badlands of eastern Montana. Wind carved these sandstone rocks into unusual formations.

National Bison Range, near Missoula, includes about 19,000 acres (7,690 hectares) and a herd of from 400 to 500 bison. The range was established in 1908.

Yellowstone National Park lies mainly in northwestern Wyoming, but three of the five park entrances are in Montana. These entrances are located near Cooke City, Gardiner, and West Yellowstone. See **Yellowstone National Park.**

Other national parklands in Montana include the sites of two famous Indian battles. These sites, preserved by the federal government, are at the Little Bighorn Battlefield National Monument, south of Hardin; and Big Hole National Battlefield, west of Wisdom. See **National Park System.**

National forests. Eleven national forests lie either entirely or partly in Montana. The largest of these are Beaverhead, Flathead, Gallatin, Kootenai, Lewis and Clark, and Lolo. The others are Bitterroot, Custer, Deerlodge, Helena, and Kaniksu.

State parks and forests. Montana has 89 state parks, monuments, and recreational areas. For further information, write to the Montana Promotion Division, Department of Commerce, Helena, MT 59620.

Annual events

January-March
"Race to the Sky" Sled Dog Race, which takes place between Helena and Seeley Lake (February); Winter Carnival in Whitefish (February); C. M. Russell Western art auction and exhibition in Great Falls (March); Winter Carnival, held in Red Lodge (March).

April-June
Miles City Jaycee Bucking Horse Sale (May); Governor's Cup Marathon in Helena (June); Music Festival in Red Lodge (June); Montana Traditional Jazz Festival in Helena (June); Custer's Last Stand Reenactment in Hardin (June).

July-September
Home of Champions Rodeo in Red Lodge (July); Libby Logger Days (July); State Fiddler's Contest in Polson (July); North American Indian Days, held in Browning (July); Wild Horse Stampede rodeo in Wolf Point (July); Yellowstone River Float, from Livingston to Billings (July); Festival of Nations, held in Red Lodge (August); Northwest Montana Fair and Rodeo in Kalispell (August); Montana State Fair and Rodeo, a major event held in Great Falls (August); Sweet Pea art festival in Bozeman (August); Western Montana Fair and Rodeo in Missoula (August); Threshing Bee and Antique Show in Culbertson (September).

October-December
Bison Roundup near Moiese (October); Northern International Stock Show and Rodeo in Billings (October); Fall Camp for Cross-Country Skiers in West Yellowstone (November); Christmas Stroll in Bozeman (December).

Land regions. Montana has two major land regions. The regions are (1) the Great Plains and (2) the Rocky Mountains.

The Great Plains of Montana are part of the vast Interior Plain of North America that stretches from Canada to Mexico. In Montana, this high, gently rolling land makes up the eastern three-fifths of the state. The land is broken by hills and wide river valleys. Here and there, groups of mountains rise sharply from the plains. These ranges include the Bears Paw, Big Snowy, Judith, and Little Rocky mountains. In the southeast, wind and water have created badland areas of gullies and colorful columns of red, yellow, brown, and white stone.

The Rocky Mountains cover the western two-fifths of Montana. This is a region of unusual beauty. The valleys have flat, grassy floors, and the mountains are forested with fir, pine, spruce, and other evergreens. In southwestern Montana, valleys may extend 30 to 40 miles (48 to 64 kilometers) between mountain ranges. In the northwest, most valleys are narrow—from 1 to 5 miles (1.6 to 8 kilometers) wide. Snow covers the higher mountains 8 to 10 months each year. There are many permanent snowfields and a few active glaciers in the higher mountain ranges. The glaciers that once covered this land carved the highest mountains into jagged peaks. The glaciers retreated, leaving a large number of clear, cold lakes.

There are more than 50 mountain ranges or groups in this area. The most important ranges include the Absaroka, Beartooth, Beaverhead, Big Belt, Bitterroot, Bridger, Cabinet, Crazy, Flathead, Gallatin, Little Belt, Madison, Mission, Swan, and Tobacco Root. The highest peaks rise in south-central Montana north of Yellowstone Park. Granite Peak in Park County is the highest mountain. It rises 12,799 feet (3,901 meters).

Faults (fractures in the earth's outer rocky shell, along which movement has taken place) create the danger of earthquakes in this region. The worst quake period recorded was in 1935, when more than 1,200 shocks were felt in 80 days in the Helena area.

Rivers and lakes. Montana is the only state drained by river systems that empty into the Gulf of Mexico, Hudson Bay, and the Pacific Ocean. The Missouri River system drains into the Gulf of Mexico by way of the Mississippi River. The Columbia system includes the Clark Fork and drains into the Pacific Ocean. The Belly, St. Mary's, and Waterton rivers reach Hudson Bay through the Nelson-Saskatchewan river system.

Montana's most important rivers are the Missouri and its branch, the Yellowstone. These rivers drain about six-sevenths of the state. The Missouri starts in southwestern Montana, as a smaller stream called the Jefferson River. At Three Forks, Montana, the Jefferson, Madison, and Gallatin rivers meet, and from this point the river is called the Missouri. The Missouri flows north past Helena, then through a deep scenic gorge called the Gates of the Mountains. It then curves eastward. Fort Peck Dam, on the Missouri in northeastern Montana, is one of the largest earth-fill dams in the United States. The Missouri leaves Montana at the North Dakota border. The main tributaries of the Missouri in Montana are the Marias, Milk, Sun, and Teton.

The Yellowstone flows north out of Yellowstone Park and then runs east and somewhat north. It joins the Missouri in North Dakota. The chief branches of the Yellowstone—the Bighorn, Clarks Fork, Powder, and Tongue rivers—flow into it from the south.

The *Continental Divide* winds through Montana. This height of land separates the waters running west into the Pacific Ocean from those that run east to the Atlantic Ocean.

The major rivers west of the divide are the Kootenai and the Clark Fork of the Columbia. The chief branches of the Clark Fork are the Bitterroot, Blackfoot, Flathead, and Thompson rivers. These western streams drain only about one-seventh of the land, but they carry as much water as the eastern Montana rivers.

One of Montana's largest lakes is Flathead Lake, which covers about 189 square miles (490 square kilometers) in the northwest. The state's largest artificially

Specially created for *The World Book Encyclopedia* by Rand McNally and World Book editors

created lake is Fort Peck Lake, on the Missouri River, which covers 383 square miles (992 square kilometers). Other important lakes include Canyon Ferry Lake and Hungry Horse and Tiber reservoirs. Yellowtail Dam, which was completed in 1966, creates a lake 71 miles (114 kilometers) long in Montana and Wyoming.

In 1967, army engineers began building the Libby Dam on the Kootenai River in northwestern Montana. The dam, which went into full operation in 1975, produces 525,000 kilowatts of power and provides flood control. It created Lake Koocanusa, which is 90 miles (145 kilometers) long and extends 42 miles (68 kilometers) into Canada. The dam is part of the Libby Dam hydroelectric project, which was completed in 1984. The $373-million project was made possible by the Columbia River Treaty between Canada and the United States.

Plant and animal life. Forests cover about one-fourth of Montana. Common trees include ashes, alders, aspens, birches, cedars, firs, larches, pines, and spruces. Flowers include the aster, bitter root, columbine, daisy, dryad, lily, lupine, poppy, and primrose. Grasslands cover much of the state.

Montana has large numbers of big-game animals. Deer are found both on the plains and in the mountains. Pronghorns thrive on the plains. Bear, moose, mountain goats, mountain sheep, bison, and elk live in the mountains. Such small fur-bearing animals as beaver, mink, and muskrat are found there. Common game birds include wild ducks and geese, grouse, pheasants, and partridges. Montana's many high, cold streams and lakes are famous for trout and grayling, two kinds of game fish.

Climate. Montana's climate varies considerably from one area to the other because the state is so large and has such great differences in elevation. The region west of the Continental Divide has cooler summers and warmer winters than the area east of the divide. In the western part of the state, the average January tempera-

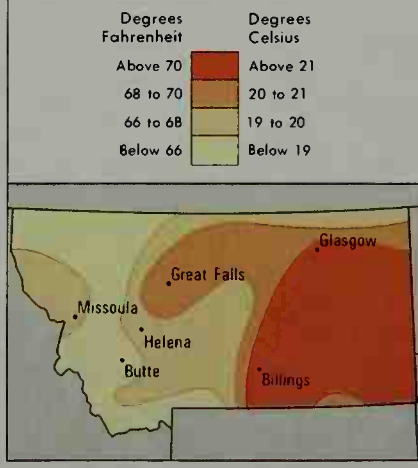
Ray Atkeson

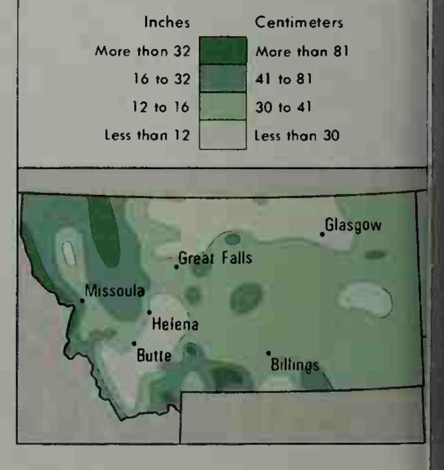
The Yellowstone River winds through Paradise Valley in the Rocky Mountain region of south-central Montana. Flat, fertile valleys stretch as far as 40 miles (64 kilometers) in this region.



Average January temperatures

Montana has cold winters. The region west of the Continental Divide has milder winters than the area east of the divide.

Average July temperatures



The state has mild summers with wide variations between the warmer east and cooler west and central areas.

Average yearly precipitation

Much of Montana has a dry climate. The mountainous western area receives more precipitation than the plains region.

ture is about 20 °F (−7 °C). Eastern Montana's January average is around 14 °F (−10 °C). July temperatures average 64 °F (18 °C) in the west, and 71 °F (22 °C) in the east. The state's record high temperature of 117 °F (47 °C) was recorded at Glendive on July 20, 1893, and at Medicine Lake on July 5, 1937. Before Alaska became a state in 1959, Rogers Pass had the lowest U.S. temperature ever recorded, −70 °F (−57 °C) on Jan. 20, 1954.

Most of Montana, except the western edge, has annual *precipitation* (rain, melted snow, and other forms of moisture) of 13 to 14 inches (33 to 36 centimeters). The western mountain areas receive more moisture than the plains. Snowfall in Montana ranges from 15 inches (38 centimeters) to 300 inches (760 centimeters) annually.

In winter, a *chinook* wind sometimes blows down the eastern mountain slopes. This warm, dry wind often melts the snow and exposes grazing land, allowing ranchers to graze cattle for part of the winter.

Economy

Service industries play a major role in Montana's economy. Taken together, they account for the largest portion of the *gross state product*—the total value of goods and services produced in the state in a year. Service industries also employ most of the state's workers. Leading service activities include education, health care, real estate, trade, and tourism.

In the rural areas of Montana's plains, major economic activities include cattle ranching, wheat farming, and the mining of coal and petroleum. In the mountains, metal mining and logging are important. Most of the manufacturing done in Montana involves the processing of farm and forest products.

The federal government owns about a fourth of the land in Montana. Federal agencies control livestock grazing, logging, and mining in those areas.

Natural resources of Montana include vast reserves of minerals and large areas of cropland, grassland, and forestland.

Soil. The soils of northern Montana are a mixture of clay, sand, and gravel left by melting glaciers. Much of the soil in the south was formed from the sediments of shallow seas that covered the area millions of years ago. Soils deposited by floods are found along the rivers and in the western valleys. The mountain soils were formed as mountain rocks eroded. In a few areas, fertile *loess* (fine-grained top soil) lies in a thick layer.

Minerals. Montana has huge deposits of two important materials—coal and petroleum. Montana's coal reserves lie under much of the plains region. Petroleum deposits also lie under the plains. Some of the petroleum deposits contain natural gas.

The western mountains of Montana have large ore reserves containing copper, gold, lead, platinum, silver, and zinc. Palladium and platinum are found in the mountains of south-central Montana, as are extensive gold and silver deposits. Other reserves include barite, clay, gemstones, gypsum, limestone, molybdenum, phosphate rock, sand and gravel, talc, and vermiculite.

Grasslands. About two-thirds of Montana is used for grazing. The most important grasses are buffalo grass, blue grama, and Western wheat grass.

Forests cover about 23 million acres (9.3 million hectares), or about one-fourth of Montana. About 8 ½ million acres (3.4 million hectares) are not available for logging. Some of these forests are in national parks and other reserves. Others are too poor in quality or too far from transportation. About half of the 14 ½ million acres (5.9 million hectares) of commercial timber is still virgin forest. Douglas-fir is the most important tree for logging. Cedar, pine, and spruce also are important.

Paul Conklin

Coal is one of Montana's most valuable mined products. This worker prepares to blast surface coal from a seam near Colstrip.

Service industries account for the largest part of the gross state product in Montana.

Community, business, and personal services contribute more to the gross state product than any other service industry group in Montana. Community, business, and personal services include private health care, motels, law firms, and repair shops. Billings and Great Falls are the leading centers of health care in Montana.

Ranking next among Montana's service industries is

Production and workers by economic activities

Economic activities	Percent of GSP* produced	Employed workers: Number of people	Employed workers: Percent of total
Community, business, & personal services	20	161,700	30
Wholesale & retail trade	17	126,900	23
Government	16	83,000	15
Finance, insurance, & real estate	14	34,700	6
Transportation, communication, & utilities	12	26,800	5
Manufacturing	8	29,500	6
Construction	5	33,200	6
Agriculture	4	40,800	8
Mining	4	6,700	1
Total	100	543,300	100

*GSP = gross state product, the total value of goods and services produced in a year.
Figures are for 1998.
Sources: *World Book* estimates based on data from U.S. Bureau of Economic Analysis and U.S. Bureau of Labor Statistics.

wholesale and retail trade. The wholesale trade of food products, mined products, and motor vehicles is important in Montana. Major types of retail businesses include discount and grocery stores, gas stations, and restaurants.

Government services rank next in terms of contributions to the gross state product. These services include the operation of public schools and hospitals, military bases, and Indian reservations. The public school system employs many people. State government offices are based in Helena. A missile base lies near Great Falls.

Finance, insurance, and real estate form Montana's fourth most important service industry. Real estate is a major part of the state's economy because of the large sums of money involved in the buying and selling of homes and other property. Many small investment companies are based in Montana.

Transportation, communication, and utilities rank fifth among the state's service industries. The transportation industry is vital to Montana's economy because goods must often be shipped great distances to reach markets. Trucking firms and railroads are the major means of transporting freight. Oil pipelines are also an important part of the transportation system. Telephone companies are the most important part of the communications sector. More information about transportation and communication appears later in this section.

Manufacturing. Goods made in Montana have a *value added by manufacture* of almost $2 billion a year. This figure represents the increase in value of raw materials after they become finished products.

Petroleum refining is the leading manufacturing activity in Montana. Most of the petroleum refineries operate in the Billings area.

The manufacture of lumber and wood products ranks second among Montana's manufacturing activities. The state has about 60 sawmills, most of them in the mountainous regions of far western Montana. Flathead, Gallatin, Lincoln, and Missoula counties produce much lumber. Columbia Falls, Libby, and Missoula have plywood plants. Other wood products include pencils, prefabricated houses, and telephone poles.

Ranking next among Montana's manufactures are machinery and food products. The state's factories make machinery for the agriculture, construction, and mining industries. Meat packing, milk processing, grain milling, and soft drink bottling are major parts of the food-processing industry. Other products made in Montana include aluminum, concrete, and paper products.

Mining. Coal and petroleum are the state's leading mined products. Almost all of Montana's coal is *subbituminous* (soft) coal, obtained from surface mines in Big Horn and Rosebud counties. Williston Basin, which is in eastern Montana, leads in petroleum production. Other oil-producing areas in the state include Carbon, Glacier, Musselshell, Pondera, Powder River, Rosebud, and Toole counties.

Montana's metals output varies widely, depending on prices and labor conditions. The state is an important source of gold, silver, copper, and lead. Many mines in the Rocky Mountain region yield metal ores. Some of the ores contain more than one type of metal. The state's largest gold mine is near Whitehall. Several metal mines lie in central Montana. Stillwater County has the nation's only mine that yields platinum-group metals.

Montana leads the nation in the production of talc and vermiculite, which are used primarily for insulation. Other products mined in Montana include gypsum, used in wallboard; limestone, used in cement; natural gas; and sand and gravel.

Agriculture. Farms and ranches cover about two-thirds of Montana's land area. Montana has approximately 27,500 farms and ranches.

Livestock and livestock products account for about half of Montana's farm income. Beef cattle are the state's leading farm product. Some of the nation's largest cattle ranches are in Montana. Farmers raise beef cattle throughout the state. They also raise dairy cattle, mainly in the river valleys of western Montana. Sheep graze in many parts of the state. The region just east of the Rocky Mountains has many hog farms.

Crops produce about half of Montana's farm income. Wheat is the state's leading crop. Wheat production is heaviest in the north-central and northeastern parts of the state. This region produces mainly spring wheat. Winter wheat is grown in the southern part of the state. Barley and hay are also important crops in Montana. Farms in the area north of Great Falls grow much of the

Economy of Montana

This map shows the economic uses of land in Montana and where the state's leading products are produced. Major manufacturing centers are shown in red.

- Mineral deposit

WORLD BOOK map

barley. Hay grows throughout Montana. The state is also an important producer of potatoes and sugar beets. Sweet black cherries are Montana's major fruit crop.

Electric power. Plants that burn coal provide about 60 percent of Montana's electric power. The state's hydroelectric plants produce almost all of the remaining power.

Transportation. Montana has about 70,000 miles (113,000 kilometers) of roads, and about 25 percent of them have a paved surface. Billings has the state's busiest airport. Three railroads provide freight service in Montana, and passenger trains serve about 10 cities. The Utah & Northern, the first railroad in Montana, entered the area in 1880.

Communication. Montana has about 85 newspapers, including about 10 dailies. The largest papers are *The Billings Gazette*, the *Great Falls Tribune*, and *The Missoulian.*

The first radio station, KFBB, began broadcasting at Great Falls in 1922. The first television stations, KXLF-TV and KOPR-TV, began operating in Butte in 1953. Today, the state has about 65 radio stations and 20 TV stations. Cable television systems and Internet providers serve many Montana communities.

Government

Constitution of Montana went into effect in 1973. It replaced a constitution that had been adopted in 1889 and amended about 30 times. Amendments may be proposed by (1) a two-thirds vote of the State Legislature, (2) a petition signed by a certain number of voters, or (3) a constitutional convention. To be adopted, a proposed amendment must be approved by a majority of the citizens voting in an election.

A constitutional convention may be proposed by either a two-thirds vote of the Legislature or a petition signed by a certain number of voters. Approval of proposals by a majority of the voters in an election is required in order to call a constitutional convention. The Constitution requires that the people vote at least once every 20 years on whether to call a constitutional convention.

Executive. The governor and lieutenant governor of Montana serve a four-year term and may be reelected any number of times. But they may not serve more than two terms in succession. These officials must remain out of office for eight years before serving in the same office again. The governor has powers of appointment involving key officials in executive departments and many state institutions. The governor also has strong veto powers over legislation. For example, the governor may veto individual items in an *appropriation* (money) bill and sign the rest of the bill into law.

The attorney general, auditor, secretary of state, and superintendent of public instruction are elected to four-year terms. These officials follow the same term limits as the governor and lieutenant governor.

Legislature consists of a 50-member Senate and a 100-member House of Representatives. Each of the 50 senatorial districts in Montana elects one senator, who serves a four-year term and may serve no more than two terms. Each of the 100 representative districts in the state elects one representative, who serves a two-year term and may serve no more than four terms.

Regular sessions of the State Legislature are held in odd-numbered years. Sessions begin on the first Monday in January and are limited to 90 legislative days. Special sessions may be called by the governor or the Legislature.

Courts. The highest court of appeals in Montana is the state Supreme Court. It consists of six associate justices and one chief justice. Justices of the Supreme Court are elected by the voters to eight-year terms. The trial courts for major civil and criminal cases are the district courts. District court judges are elected to six-year terms from each of 21 judicial districts. Municipal courts, police courts, and justice of the peace courts handle less serious cases.

Local government. Fifty-three of the state's 56 counties elect three county commissioners to govern the county. The commissioners serve six-year terms. Elected chief executives administer two of the other counties, and a manager appointed by commissioners runs the remaining county. About 120 of Montana's cities and towns have a mayor-council government. Several other cities in Montana, including Bozeman, Great Falls, and Helena, use the council-manager system.

Revenue. Taxes provide about half of the state government's *general revenue* (income) in Montana. Most of the rest comes from federal grants and programs. Much of the tax revenue in the state comes from income taxes and a tax on coal production. The state government also taxes motor fuels, property, and other items. Montana has no general sales tax.

Politics. In the early days, the Democratic Party dominated Montana politics. Many people voted Democratic

The governors of Montana

	Party	Term

*Democrat-Populist

because they came to Montana from the traditionally Democratic South. Montanans joked that part of the Confederate Army never surrendered, it just retreated to Montana.

During the 1900's, the Republican and Democratic parties shared power in Montana. About two-thirds of the state's governors were Democrats. Most of the Republican gubernatorial victories took place in the last half of the 1900's.

Montana has given its electoral votes to the Republican candidate in about 60 percent of the presidential elections. For more information on the state's voting record in presidential elections, see **Electoral College** (table).

History

Indian days. Before the white settlers arrived, two groups of Indian tribes lived in the region that is now Montana. The Arapaho, Assiniboine, Blackfeet, Cheyenne, Crow, and Gros Ventre (also called Atsina) tribes lived on the plains. The mountains in the west were the home of the Bannock, Flathead, Kalispel, Kutenai, and Shoshone tribes. Other nearby tribes such as the Sioux, Mandan, and Nez Perce hunted in the Montana region.

Exploration. French trappers may have visited the Montana area as early as the 1740's. The American explorers Meriwether Lewis and William Clark led their expedition across Montana to the Pacific Coast in 1805. They returned in 1806 and explored parts of Montana both going and coming. After 1807, fur traders became active there. In 1841, Jesuit missionaries established St. Mary's Mission, the first attempt at a permanent settlement, near what is now Stevensville. In 1847, the American Fur Company built Fort Benton on the Missouri River. The town that formed there is Montana's oldest continuously populated town.

The United States got most of what is now Montana as part of the Louisiana Purchase (see **Louisiana Purchase**). The northwestern part was gained by treaty with Britain in 1846. At various times, parts of Montana were in the territories of Louisiana, Missouri, Nebraska, Dakota, Oregon, Washington, and Idaho.

The gold rush. In 1862, prospectors found gold in Grasshopper Creek in southwestern Montana. Other gold strikes followed, and wild mining camps grew around the gold fields. These included Bannack, Diamond City, Virginia City, and others.

The mining camps had almost no effective law enforcement. Finally, the citizens took the law into their own hands. One famous incident involved the two biggest gold camps—Bannack and Virginia City. The settlers learned that their sheriff, Henry Plummer, was actually an outlaw leader. The men of Bannack and Virginia City formed a *vigilance committee* to rid themselves of the outlaws. These vigilantes hanged 21 men, including Plummer, in January 1864. The vigilantes adopted as their symbol the numbers 3-7-77. These numbers may have referred to dimensions of a grave—3 feet wide, 7 feet deep, and 77 inches long. Or the symbol may have been associated with masonic ritual because many of the vigilantes were members of the Masons, a fraternal organization. Many outlaws were hanged or driven from Montana.

Many of the early prospectors came from the South, some from Confederate Army units that broke up early in the Civil War (1861-1865). One of the major gold fields was called Confederate Gulch, because three Southerners found the first gold there.

During the boom years, gold dust was the principal money. For example, missionaries did not pass collection plates at services. They passed a tin cup for gold dust. Chinese laundries even found gold in their wash water when they had finished washing the miners' clothing.

Sidney Edgerton, an Idaho official, saw the need for better government of the wild mining camps. At the time, Montana was part of the Idaho territory. Edgerton traveled to Washington, D.C., to lobby for territorial status. Montana became a territory on May 26, 1864, and Edgerton served as its first governor.

The cattle industry began in Montana in the mid-1850's, when Richard Grant, a trader, brought the first herd to the area from Oregon. In 1866, Nelson Story, a cattleman, drove a thousand longhorn cattle from Texas to Montana. Story's herd started the Montana cattle industry in earnest. The coming of the Northern Pacific Railroad in 1883 opened the way to the eastern markets and caused even more growth. However, disaster struck the cattle industry in the bitterly cold winter of 1886-1887. Cattle died by the thousands during the severe winter. Ranching continued after this, but on a smaller scale.

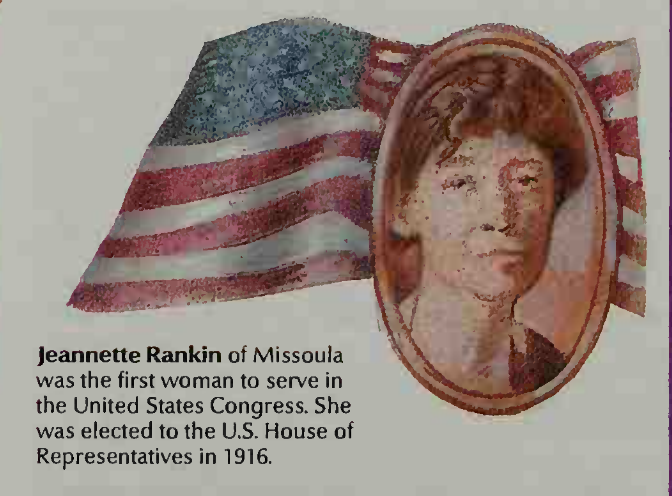
Indian fighting. Two of the most famous Indian campaigns in American history were fought in the Montana Territory. On June 25, 1876, Sioux and Cheyenne Indians wiped out part of the 7th Cavalry Regiment under Lieutenant Colonel George A. Custer. This famous battle, known as "Custer's Last Stand," was fought near the Little Bighorn River in southeastern Montana. The last serious Indian fighting in Montana started when the U.S. gov-

Montana Historical Society

The gold rush brought prospectors to Montana. Helena, shown here in 1866, sprang up after gold was discovered at Last Chance Gulch in 1864.

Historic Montana

Pompey's Pillar, a famous landmark for pioneers migrating westward, rises 200 feet (61 meters) above the Yellowstone River. Explorer William Clark first saw it in 1806.



Copper mining increased in 1882 after copper was discovered in the Anaconda silver mine in Butte.

Custer's Last Stand took place in 1876 when Custer and about 210 of his troops were killed in the Battle of the Little Bighorn.

Chief Joseph and the Nez Perce Indians surrendered to federal troops at Bears Paw Mountains in 1877. This ended Indian fighting in Montana.

Jeannette Rankin of Missoula was the first woman to serve in the United States Congress. She was elected to the U.S. House of Representatives in 1916.

Important dates in Montana

1803 Eastern Montana became U.S. territory through the Louisiana Purchase.

1805-1806 Lewis and Clark explored part of Montana on their journey to and from the Pacific Coast.

1846 The Oregon treaty with England made northwestern Montana part of the United States.

1862 Gold was discovered on Grasshopper Creek.

1864 Congress established the Montana Territory.

1876 The Sioux and Cheyenne Indians defeated U.S. Cavalry troops at the Battle of the Little Bighorn.

1877 Chief Joseph and the Nez Perce Indians surrendered to federal troops after several battles.

1889 Montana became the 41st state on Nov. 8.

1910 Congress established Glacier National Park.

1940 Fort Peck Dam was completed.

1951 The first oil wells in the Montana section of the Williston Basin started production.

1955 The Anaconda Aluminum Company dedicated a $65-million plant at Columbia Falls.

1966 Construction of Yellowtail Dam was completed.

1973 A new state constitution went into effect.

1984 The Libby Dam hydroelectric project, begun in 1967, was completed.

2000 Judy Martz became the first woman to be elected governor of Montana.

ernment tried to move the Nez Perce Indians from their lands in Oregon. Chief Joseph of the Nez Perce led his tribe toward Canada through Montana. The Indians and U.S. troops fought several small battles in Idaho, and then a two-day battle at Big Hole in southwestern Montana. Troops under Colonel Nelson A. Miles captured Chief Joseph's Indians about 40 miles (64 kilometers) from the Canadian border. See **Indian wars** (The Sioux wars; The Nez Perce War).

Statehood. Between 1880 and 1890, the population of Montana grew from about 39,000 to nearly 143,000. The people of Montana first asked for statehood in 1884, but they had to wait five years. Finally, Montana was admitted to the United States as the 41st state on Nov. 8, 1889. Joseph K. Toole of Helena became the first governor of the state.

Much of Montana's growth during the 1880's and 1890's came because of the mines at Butte. The earliest mines produced gold. Then silver was discovered in the rock ledges of Butte Hill. Later, the miners found rich veins of copper. Miners came to Butte from Ireland, England, and other areas of Europe. Smelters were built in Anaconda and Great Falls, and more men were hired to operate them. Butte Hill became known as the *Richest Hill on Earth.*

Marcus Daly and William A. Clark led the development of Butte copper and controlled many of the richest mines. The two men became rivals in both business and politics. The great wealth produced by the mines gave both men great power. Daly built the town of Anaconda and spent large sums of money in a campaign to make it the state capital. Clark opposed Daly's plan, and the voters picked Helena as the capital.

Clark wanted to be a U.S. senator, but Daly opposed him. In the campaign of 1899, Clark was accused of bribery. He won the election but resigned rather than face an investigation by a Senate committee. Two years later, Clark won his Senate seat in a second election. He was helped by F. Augustus Heinze, another mine owner. Heinze had arrived in Butte long after Daly and Clark became millionaires. But Heinze became wealthy through clever use of mining law and court suits.

First Daly, then the others sold their properties to a single corporation, which became the Anaconda Company. The company organized an electric power company, built a railroad, and constructed dams. It also controlled forests, banks, and newspapers. Anaconda became so important in the life of the state that Montanans referred to it simply as "The Company."

Progress as a state. During the early 1900's, Montana made increasing use of its natural resources. New dams harnessed the state's rivers, providing water for irrigation and electric power for industry. The extension of the railroads assisted the processing industries. New plants refined sugar, milled flour, and processed meat. In 1910, Congress created Glacier National Park, which became an attraction for the tourists.

Jeannette Rankin of Missoula, a leader in the campaign for women's rights, was elected to the U.S. House of Representatives in 1916. She was the first woman to serve in Congress. She won fame in 1941 as the only member of Congress to vote against U.S. entry into World War II. Rankin said she did not believe in war and would not vote for it.

Depression years. Montana suffered during the Great Depression of the 1930's. Demand for the state's metals dropped because of the nationwide lag in production. Drought contributed to the drop in farm income brought on by the Depression.

However, state and federal programs continued to develop Montana's resources during the 1930's. The building of the giant Fort Peck Dam helped provide jobs. Completion of the dam in 1940 provided badly needed water for irrigation. Other projects included insect control, irrigation, rural electrification, and soil conservation. Construction of parks, recreation areas, and roads also continued under government direction.

The mid-1900's. Montana's economy boomed during World War II (1939-1945). The state's meat and grain were in great demand, and its copper and other metals were used in the war effort. After the war, lower prices for grain reduced agricultural income. Many people moved from farming areas to towns and cities to find jobs. Some small farming towns were abandoned.

Montana's petroleum industry expanded rapidly in the early 1950's, when major oil fields were discovered in the Williston Basin along the Montana-North Dakota border. Wells in the new Montana fields began pumping oil in 1951. In 1955, the Anaconda Aluminum Company opened a $65-million plant in northwestern Montana, and aluminum products became important to the state's economy. During the 1960's, Anaconda spent more than $50 million to improve operations at the Butte mines and to make better use of the remaining ore there.

Tourism grew as an important source of income in Montana during the mid-1900's. The state developed more parks and historic sites, and private developers opened dude ranches, summer resorts, and skiing centers. Such ski areas as Big Mountain, near Whitefish, helped extend the tourist season through winter.

The state's irrigation and water conservation programs were also expanded. In 1966, Yellowtail Dam on the Bighorn River in southern Montana was completed. This dam provides water for electric power, irrigation, and recreation. Work began in 1967 on the $373-million Libby Dam hydroelectric project on the Kootenai River in northwestern Montana. The power plant there began operation in 1975. The project was completed in 1984.

The late 1900's. In 1972, Montana voters narrowly approved a new state Constitution. The Constitution went into effect in 1973.

Montana's gas, oil, and coal industries expanded rapidly during the 1970's, when an energy shortage developed in the United States. Coal production increased sharply, from less than 3 million to almost 40 million tons per year. Huge, open-pit strip mines operated at Colstrip and other southeastern Montana sites. The Montana Power Company built four coal-fired electric power plants at Colstrip. A 30 percent coal severance tax contributed needed funds to the state. But in the early 1980's, fuel prices fell, and Montana's production leveled off.

Montana's traditionally important industries experienced major difficulties during the 1980's. Farmers suffered hardships brought on by drought, insect pests, and low farm product prices. The lumber and mining industries reduced their work forces. But the economy improved in the 1990's, as farm problems eased and the

state's construction and manufacturing industries gained strength.

Recent developments. Montana today remains a state rich in natural resources. But technological changes have cost jobs. State leaders seek to broaden the economy and ensure a successful future for the state by expanding the manufacturing and travel, recreation, and retirement industries. The Science and Technology Alliance, a state agency created in 1985, helps finance research to look for new uses for raw materials.

In 2000, voters elected Judy Martz governor. When Martz took office in 2001, she became the first woman to serve as the state's governor.

Montana, Joe (1956-), was one of the greatest quarterbacks in professional football history. Montana became known for his leadership, his accurate passing, and his durability. He led the San Francisco 49ers of the National Football League (NFL) to Super Bowl victories at the end of the 1981-1982, 1984-1985, 1988-1989, and 1989-1990 seasons. Montana holds several Super Bowl passing records as well as an NFL record for passing for more than 3,000 yards in each of six seasons.

Joseph Clifford Montana, Jr., was born in Monongahela, Pennsylvania. He attended the University of Notre Dame from 1975 to 1979. He led Notre Dame to the unofficial national college football championship in 1977. Montana was selected by San Francisco in 1979 in the third round of the college players' draft and became the team's starting quarterback in 1981. Montana was traded to the Kansas City Chiefs in 1993. He announced his retirement as a player in 1995. Carlton Stowers

Montana, University of, is a coeducational state-supported school in Missoula, Montana. It has a college of arts and sciences and schools of fine arts, forestry, law, business administration, education, journalism, and pharmacy. The university awards associate, bachelor's, master's, doctor of education, and doctor of philosophy degrees. It also has a biological station and a 30,000-acre (12,000-hectare) forest experiment station. In addition, it operates a bureau of business and economic research, a wildlife research unit, a wood chemistry laboratory, an immunological research institute, a center for Asian studies and ethics in public affairs, and the Montana Entrepreneurship Center. It was chartered in 1893 and is part of the Montana University System.

Critically reviewed by the University of Montana

Montana State University is a state-assisted coeducational school with campuses in Billings, Bozeman, and Havre, Montana. It has colleges of agriculture, arts and architecture, business, education, engineering, letters and sciences, and nursing. Courses lead to bachelor's, master's, and doctor's degrees. Montana State was founded in 1893. Eastern Montana College and Northern Montana College became campuses of the university in 1994. Montana State University is part of the Montana University System.

Montcalm, *mahnt KAHM* or *mawn KAHLM,* **Marquis de,** *mahr KEE duh* (1712-1759), a French general, was killed in one of the last great battles between the French and British in America. Montcalm was wounded on the Plains of Abraham in the battle for the city of Quebec. He died in the city a few hours later. The British commander, General James Wolfe, also died in the action.

Montcalm defeated the British in the first part of the French and Indian War (1754-1763). He captured Oswego and Fort William Henry on Lake George, and successfully defended Ticonderoga. But lack of support from the French government handicapped him.

As the war progressed, Montcalm realized that a decisive battle would be fought between the French and British at Quebec. He gathered his main forces to defend the city, and threw back the first British attacks. But Wolfe appeared with his whole force on the Plains of Abraham on Sept. 13, 1759. Montcalm led the French attack, but his troops broke under the heavy fire of the British. The American historian Francis Parkman described Montcalm's death in the dramatic climax of his book *Montcalm and Wolfe* (1884).

Detail of a portrait by an unknown artist. Marquis de Montcalm, Paris (Public Archives of Canada)

Marquis de Montcalm

Louis Joseph de Montcalm-Gozon was born in France, near Nîmes. He joined the French army at the age of 12, and became a captain at 17. By 1756, he had become commander of the French troops in America.

Fred W. Anderson

Monte Albán, *MOHN tay ahl BAHN,* was the capital and largest city of the empire of the Zapotec Indians. It stood on a mountaintop near what is now the southern Mexican city of Oaxaca (see **Mexico** [political map]). *Monte Albán* means *White Mountain* in Spanish and also refers to the mountain on which the city's ruins stand. No one knows what the Zapotec called the city.

The Zapotec founded Monte Albán about 500 B.C. The city developed trade links with the city of Teotihuacán in what is now Mexico and the Maya city of Tikal in present-day Guatemala. Monte Albán's population grew to about 25,000 between the A.D. 200's and 700's.

The architecture and culture of Monte Albán influenced cultures in other parts of what are now Mexico and Central America. The city had many stone structures, including pyramids with temples on top, palaces, plazas, and tombs. Large stone slabs were decorated with carvings of the city's defeated enemies and included their names in *hieroglyphics* (picture writing).

The decline of Teotihuacán contributed to the abandonment of Monte Albán about A.D. 750. The Mixtec Indians later buried their leaders in the deserted city. Today, Monte Albán is a major archaeological site and tourist attraction. Jose A. Fernandez Valbuena

See also **Zapotec Indians.**

Monte Carlo, *MAHN tee KAHR loh* (pop. 11,599), is the tourist region of the principality of Monaco. Monte Carlo lies on the Riviera, which is 9 miles (14 kilometers) from Nice, France, and overlooks the Mediterranean Sea. Monte Carlo is a popular resort area. Exports from the region include olive oil, oranges, and perfumes.

Monte Carlo has been famous as a gambling center since the middle of the 1800's. It has a government-owned casino and two privately owned gambling establishments. Citizens of Monaco are forbidden to gamble at any of these facilities. But each year thousands of visitors come to play roulette, baccarat, and other games of chance. Janet L. Polasky

See also Monaco.

Monte Cassino, *MAHN tee kuh SEE noh,* is an abbey in Italy, located between Rome and Naples. Here St. Benedict founded the Roman Catholic Benedictine order (see **Benedictines**). About A.D. 529, St. Benedict sought refuge from persecution inside the ruined city of Cassino. Later, St. Benedict and his followers built the monastery on a height above the town.

The Benedictine order at Monte Cassino reached the height of its influence from 1058 to 1087. Abbot Desiderius, who later became Pope Victor III, ruled it during that time. The monks of Monte Cassino produced manuscripts and paintings which became famous throughout the world. In 1071, a new abbey church was consecrated. It was named a cathedral in 1321.

In 1866, when Italy dissolved many of its monasteries, Monte Cassino became a national monument. Its buildings held a monastery, a school for laymen, and two seminaries. The abbey's library contained an excellent collection of manuscripts. During World War II, the Allied advance was held up at Cassino and the abbey was bombarded. However, most of Monte Cassino's treasures were saved. By 1952, the Italian government had rebuilt the buildings along their original lines. They put the masterpieces of the monastery on public display.

Stanley K. Stowers

Monte Cristo, *MAHN tee KRIHS toh* or *MOHN tay KREES toh,* is a small, barren Italian island in the Mediterranean Sea. For location, see **Italy** (terrain map). The island covers 4 square miles (10 square kilometers). In ancient times it was known as *Oglasa.* It became famous through Alexandre Dumas's novel, *The Count of Monte Cristo.* The novel tells how the hero discovered a treasure there. Most of the island is a mountain of granite, rising 2,000 feet (610 meters) above sea level. Benedictine monks once had a monastery on Monte Cristo. But they abandoned it after pirates attacked them in 1553. More than 300 years later, the Italian government tried to establish a *penal colony* (prison settlement) on Monte Cristo. It soon gave up the attempt. David I. Kertzer

Montenegro, *MAHN tuh NEH groh,* is one of the two republics of Yugoslavia. Serbia is the other. In 1918, Montenegro became part of the Kingdom of the Serbs, Croats, and Slovenes, later renamed Yugoslavia. In 1946, Yugoslavia was organized as a federal state consisting of six republics, one of which was Montenegro. Between June 1991 and March 1992, four of the republics—Bosnia-Herzegovina, Croatia, Macedonia, and Slovenia—declared their independence. In April 1992, Montenegro joined Serbia in forming a new, smaller Yugoslavia. In 2002, the leaders of Montenegro, Serbia, and the federal government of Yugoslavia developed plans to rename the country Serbia and Montenegro.

Montenegro covers 5,333 square miles (13,812 square kilometers) and has about 650,000 people. Montenegro's name in Serbo-Croatian, the republic's language, is *Crna Gora,* which means *black mountain.* The capital and largest city is Podgorica (formerly Titograd).

Government. A president heads Montenegro's government. A 125-member assembly makes the republic's laws. The voters elect the president and the assembly members to 4-year terms. The Montenegrin Democratic Party of Socialists (formerly the Montenegrin League of Communists) is the republic's chief political party.

People. About 68 percent of the people of Montenegro are Montenegrins, a people closely related to the Serbs. Like the Serbs, the Montenegrins speak Serbo-Croatian, use the Cyrillic alphabet, and, traditionally, have belonged to the Serbian Orthodox Church. Minority groups in Montenegro include Albanians, Muslim Slavs, and Serbs. Children in Montenegro are required to attend school from the ages of 7 to 15. Montenegro has a university in Podgorica.

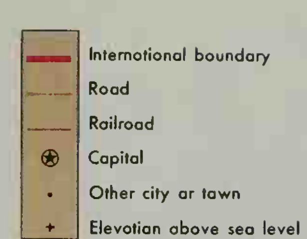
Montenegro's urban population began to grow in the 1950's, as people moved to the cities to seek jobs. Between 1953 and 1981, the percentage of city dwellers rose from 14 to about 50 percent.

Land and climate. Mountains cover most of Montenegro, and thick forests grow over much of the republic. A narrow strip of land lies along the Adriatic Sea. Most of Montenegro has cold, snowy winters. Summers are warm in the valleys but cool in the mountains. The coast has a mild climate.

Economy. When Montenegro was part of the larger Yugoslavia, it had one of the weakest economies of the six republics. For many years, a poor network of roads and railroads held back economic development. But the opening in 1976 of a railroad line between Bar, Montenegro's major seaport, and Belgrade, Yugoslavia's capital, improved the transportation system and helped the economy somewhat. Montenegro has large deposits of bauxite, coal, and lead. Factories manufacture aluminum, cement, iron and steel, and paper. The most important crops are corn, olives, potatoes, tobacco, and wheat. Farmers also grow cherries, figs, grapes, peaches, pears, and plums, and raise cattle, hogs, and sheep.

Tourism is a major source of income for Montenegro. Many vacationers come to Montenegro's coast to enjoy the warm climate and scenic beaches. People who fish, hike, hunt, and ski also visit the mountains.

Montenegro has airports in Ivangrad, Podgorica, and Tivat. The leading daily newspaper is *Pobjeda.*



History. Present-day Montenegro became part of the Roman Empire in about 11 B.C. Slavs settled in the region in the 600's. It became part of Serbia in the late 1100's. The Ottoman Empire, based in modern-day Turkey, defeated the Serbs in the Battle of Kosovo Polje in 1389. Local nobles ruled Montenegro on behalf of the Ottomans until 1516, when Serbian Orthodox bishops of the monastery at Cetinje began to rule part of it. By the late 1700's, their rule extended to all of Montenegro. In 1852, Montenegro's ruler took the title of prince, and the position of bishop became a separate office.

In 1878, the Congress of Berlin, a meeting of European leaders, formally recognized Montenegro as independent. The congress granted new lands to Montenegro, about doubling its size. Prince Nicholas took the throne in 1860 and declared himself king in 1910.

In the early 1900's, a movement to unite Serbs and other Slavic peoples gathered strength in the region. In 1918, townspeople deposed the king, and Montenegro became part of the new Kingdom of the Serbs, Croats, and Slovenes. But rural villagers organized militias to resist incorporation into the kingdom. Their resistance continued until the mid-1920's.

During World War II (1939-1945), Italian and then German troops occupied parts of Montenegro. A resistance movement led by a group of Communists called Partisans fought the Italian and German troops. By 1945, the Communists had gained control of all of Yugoslavia. In

Montenegro

WORLD BOOK maps

Montenegro is one of the two republics of Yugoslavia. Serbia is the other. Montenegro lies on the Balkan Peninsula of Europe.

Montenegro's coastline rises sharply to the mountains at Petrovac, a town on the Adriatic Sea. Olive trees grow on the mountain slopes surrounding the town. Montenegro's name in Serbo-Croatian means *black mountain,* and mountains cover most of the republic.

Schmied, ZEFA

1946, Montenegro became one of the six republics of Yugoslavia.

In 1990, Montenegro held its first multiparty elections. Between June 1991 and March 1992, four Yugoslav republics—Croatia, Slovenia, Macedonia, and Bosnia-Herzegovina—declared their independence. In April 1992, Serbia and Montenegro formed a new Yugoslavia. See **Podgorica; Serbia; Yugoslavia.**

In 2000, many people in Montenegro began pressing for independence from Serbia, which held most of the power in Yugoslavia. In response, the leaders of the two republics announced plans in 2002 to create a new constitution and to rename the country Serbia and Montenegro. Sabrina P. Ramet

Monterey, *MAHN tuh RAY,* California (pop. 29,674), is a port city that lies along the southern end of Monterey Bay (see **California** [political map]). It is on the Monterey Peninsula, home to many artists and writers.

Sebastián Vizcaíno, a Spanish explorer, landed in what is now Monterey in 1602. The area was settled in 1770, when the Spaniards founded a *presidio* (military fort) there. The city was California's capital under Spanish and Mexican rule, and its capital as a United States territory until 1850.

Today, the Salinas metropolitan area, which includes Monterey, has a population of 401,762. Tourists, conventions, and music festivals provide much of the area's income. The Monterey Bay Aquarium is one of the world's largest aquariums. The shops, restaurants, and other attractions of Cannery Row, near the aquarium, draw many visitors. The Defense Language Institute, a language school for U.S. military personnel, and the Naval Postgraduate School are in the city. California State University at Monterey Bay is nearby. Monterey has a mayor-council-manager government. James J. Rawls

Monterrey, *mohn tehr RAY* (pop. 1,108,499; met. area pop. 3,273,332), is one of the largest cities in Mexico. Monterrey is located in a fertile valley near the Texas border (see **Mexico** [political map]). The Pan American Highway links Monterrey with Laredo, Texas, 140 miles (225 kilometers) to the northeast.

Monterrey is known for its iron and steel foundries, and for its breweries. More than 500 factories produce textiles, cement, and other products. A natural gas pipeline between Texas and Monterrey aided the city's industrial growth. Monterrey has old Spanish-style buildings and many modern structures. The nearby Technological Institute attracts many U.S. students. Spanish settlers founded Monterrey about 1560. It was incorporated as a city in 1596. James D. Riley

Montesquieu, *MAHN teh SKYOO* (1689-1755), was a French philosopher. His major work, *The Spirit of the Laws* (1748), influenced the writing of many constitutions, including the Constitution of the United States.

Montesquieu believed that laws underlie all things—human, natural, and divine. One of philosophy's major tasks was to discover these laws. It was difficult to study humanity because the laws governing human nature were complex. Yet Montesquieu believed these laws could be found by *empirical* (experimental) methods of investigation (see **Empiricism**). Knowledge of the laws would ease the ills of society and improve life.

Montesquieu said there were three basic types of government—monarchal, republican, and despotic. A monarchal government had limited power placed in a king or queen. A republican government was either an aristocracy or a democracy. In an aristocracy, only a few had power. In a democracy, all had it. A despotic government was controlled by a tyrant, who had absolute authority. Montesquieu believed legal systems should vary according to the basic type of government.

Bettmann Archive

Montesquieu

Montesquieu supported human freedom and op-

posed tyranny. He believed that political liberty involved separating the legislative, executive, and judicial powers of government. He believed that liberty and respect for properly constituted law could exist together.

Montesquieu, whose real name was Charles de Secondat, was born near Bordeaux. He inherited the title Baron de la Brède et de Montesquieu. He gained fame with his *Persian Letters* (1721), which ridiculed Parisian life and many French institutions. He also criticized the church and national governments of France. Montesquieu was admitted to the French Academy in 1727. He lived in England from 1729 to 1731 and came to admire the British political system. James Creech

Montessori, *MAHN tuh SAWR ee,* **Maria** (1870-1952), was an Italian educator and physician. She won international fame for designing an educational system to aid children in the development of intelligence and independence. Her educational approach became known as the *Montessori method* (see **Montessori method**). Montessori schools exist worldwide.

Granger Collection
Maria Montessori

Montessori was born in Chiaravalle, near Ancona, Italy. She became the first Italian woman to receive a medical degree when she graduated from the University of Rome in 1896. Early in her medical career, Montessori worked with children in mental asylums. In 1899, she became codirector of the State Orthophrenic School for underdeveloped children. The educational methods she devised were so successful that her learning-disabled students passed reading and writing examinations for normal children. In 1907, she opened her first school, where she taught normal preschool children from poor families. Montessori lectured extensively on her methods throughout the world and wrote several books, including *The Montessori Method* (1912) and *The Absorbent Mind* (1949). Paula P. Lillard

Montessori method, *MAHN tuh SAWR ee,* is an educational system designed to aid children in the development of intelligence and independence. The system was developed by Maria Montessori, an Italian educator and physician, in the early 1900's (see **Montessori, Maria**). Thousands of schools throughout the world use the Montessori method.

Montessori educators establish special environments to meet the needs of students in three distinct age groups: infancy to $2\frac{1}{2}$ years, $2\frac{1}{2}$ to $6\frac{1}{2}$ years, and $6\frac{1}{2}$ through 12 years. The students learn through activities that involve exploration, manipulation, order, repetition, abstraction, and communication.

Children from infancy through the age of 6 develop mentally through their senses. Thus, Montessori educators encourage students in the first two age groups to use their senses of touch, sight, hearing, smell, and taste to explore and manipulate materials in their immediate environment. Children from 6 through 12 years of age can deal with abstract concepts based on their newly developed powers of reasoning, imagination, and creativity. Montessori educators assist these children by presenting special lessons and materials. After a presentation, instructors help the students explore the topic independently. In most cases, Montessori students carry out their exploration in groups. The groups are made up of classmates who are of different ages and who have chosen to work with one another. The groups then report their findings to the entire class, both orally and in writing.

The Association Montessori Internationale (AMI) sets international standards for the education of Montessori teachers and teacher trainers and for Montessori schools. In the United States, the American Montessori Society (AMS) also trains teachers and certifies schools. But many U.S. schools that use the name *Montessori* do not have AMS or AMI certification. The AMS has headquarters in New York City. AMI headquarters are in Amsterdam in the Netherlands. Paula P. Lillard

Monteux, *mawn TUH,* **Pierre** (1875-1964), was a leading French conductor of the 1900's. He conducted a broad repertory with great authority and finesse, using a technique notable for its restraint.

Monteux was born in Paris. He first gained attention as a conductor in 1911 with the Diaghilev Ballets Russes. He conducted several important premieres for this ballet company, particularly the first performance of Igor Stravinsky's *The Rite of Spring* (1913).

In 1917, Monteux went to the United States to conduct at the Metropolitan Opera. From 1919 to 1924, he conducted the Boston Symphony Orchestra. Monteux conducted in Europe from 1924 to 1936. He conducted the San Francisco Symphony Orchestra from 1936 to 1952. From 1960 until his death, Monteux served as principal conductor of the London Symphony Orchestra.

Martin Bernheimer

Monteverdi, *MAHN tuh VAIR dee,* **Claudio,** *KLOW dyoh* (1567-1643), was an Italian composer. His works greatly influenced the change from the strict style of Renaissance music to the emotional style of the baroque movement (see **Baroque**). He is often considered the first important composer of opera, and his *Orfeo* (1607) the first modern opera. Only two of his other operas have survived in complete form—*The Return of Ulysses* (1641) and *The Coronation of Poppea* (1642), a great masterpiece.

Bettmann Archive
Claudio Monteverdi

Monteverdi was a genius at composing for orchestra. In writing for strings, he pioneered in using an agitated effect called *tremolo* and a plucking technique called *pizzi-*

cato. He was also one of the great composers of religious music and madrigals (see **Madrigal**). Monteverdi's *Vespers* (1610) combined church chants with devices that were previously associated with *secular* (nonreligious) music using chords. These devices included *arias* (vocal solos) and *recitative* (speech recited to music).

Monteverdi was born in Cremona. From 1590 to 1612, he was employed as a musician and composer by the Duke of Mantua. From 1613 until his death, Monteverdi served as choirmaster of the Cathedral of St. Mark in Venice. Beginning in 1637, Monteverdi also served as composer for the first public opera house in Venice.

Charles H. Webb

Montevideo, *MAHN tuh vih DAY oh* (pop. 1,303,182), is the capital, largest city, and chief port of Uruguay. It lies at the midpoint of Uruguay's coast, where an *estuary* (bay) called the Río de la Plata meets the Atlantic Ocean. For location, see **Uruguay** (map).

The center of the city is Independence Plaza, a park surrounded by highly decorative buildings. These buildings include the Government House, the Museum of Natural History, the Salvo Palace, the Solís Theatre, and the Victoria Plaza Hotel. The Avenida 18 de Julio runs east from the plaza and passes through the main business district. This avenue gets its name from July 18, 1830, the date Uruguay adopted its first constitution. West of the plaza, an arch leads to a historic district called Old Town. This district has many buildings that date from the 1700's or 1800's.

Most of Montevideo's people are of European descent. A small minority of people are of African descent. About two-fifths of all Uruguayans live in Montevideo. Most people in the city dwell in single-family houses or modern apartment buildings. There are few slums. The city has an excellent system of public education and is the home of the University of the Republic and the Technical University of Uruguay.

The Uruguayan government employs more than one-third of the workers of Montevideo. The city's important industries include textile manufacturing, banking, and tourism. Most of Uruguay's exports and imports pass through Montevideo's port.

Montevideo was founded in 1726 by Bruno Mauricio de Zabala, the Spanish colonial governor of Buenos Aires, Argentina. Beginning in the late 1800's, the city expanded rapidly as the result of immigration from European countries, including Spain, Italy, France, and the United Kingdom. This heritage makes Montevideo seem much like a European city. Since 1990, the city has been governed by the Broad Front, a leftist coalition party.

Montezuma II, *MAHN tuh ZOO muh* (1466?-1520), was an Aztec emperor who ruled in what is now Mexico from 1502 to 1520. The Spaniards took control of the Aztec empire in 1521, shortly after his death. His name is also spelled Moctezuma (pronounced *MAHK tay SOO mah*) or Motecuhzoma (*maw TAY kwah SOH mah*).

During his reign, Montezuma extended the Aztec domain to cover much of south-central Mexico. However, the people Montezuma conquered disliked him because he taxed them heavily.

In 1519, Hernando Cortés, the leader of a Spanish expedition, arrived in Mexico. Some historians believe that Montezuma and his people thought Cortés might be Quetzalcóatl—the White God of the Aztec—or his representative. At first, Montezuma welcomed the Spaniards with gold ornaments and other gifts. He hoped that the gifts would satisfy the Europeans and that they would leave his empire. But the gifts only made the Spaniards eager to see the riches of the Aztec capital, Tenochtitlan (now Mexico City).

In late 1519, Cortés took Montezuma hostage and tried to control the empire with Montezuma as a puppet ruler. In 1520, the Aztec rebelled against the Spaniards and attacked the emperor's palace. During the attack, a stone hit and injured Montezuma. He died several days later. The Aztec claim the Spaniards slit Montezuma's

Montfort, *MAHNT fuhrt* or *mawn FAWR,* **Simon de,** *see MAWN duh* (1208?-1265), an English statesman and soldier, contributed to the growth of parliamentary government in England. He has been called "the father of the House of Commons."

For many years, Montfort was a favorite of King Henry III. But he lost favor because of his desire for political reform. Henry III wanted to rule as he pleased, and Montfort led a rebellion aimed at limiting the king's power by law. King Henry and his son (later Edward I) took up arms, but Montfort captured them both at the battle of Lewes in 1264. Shortly after, Montfort assembled a parliament that won him fame.

Parliament had been only another name for the king's Great Council of barons and prelates, though some commoners had served in the past. Montfort wished to give more people a voice in affairs. He called to this Parliament of January 1265 two representatives from each shire and two from each town and borough.

Montfort was killed a few months later in the battle of Evesham. His tomb became an English shrine.

Montfort was born in France. When he was 21, he came to England to claim the lands and title formerly held by his great-grandfather. Ten years later, he received the title Earl of Leicester. John Gillingham

Montgolfier brothers, *mahnt GAHL fee uhr* or *mawn gawl FYAY,* were French papermakers who in-

vented the hot-air balloon. Jacques Étienne Montgolfier (1745-1799) and Joseph Michel Montgolfier (1740-1810) experimented with large bags filled with hot gases produced by burning wool and moist straw.

The Montgolfier brothers were born in Annonay. They first launched small balloons in 1782 and demonstrated a larger balloon in June 1783. In September, they launched a balloon carrying a sheep, a duck, and a rooster as King Louis XVI looked on. The next month, a French scientist, Jean F. Pilâtre de Rozier, ascended in a Montgolfier balloon anchored to the ground. On Nov. 21, 1783, he and a French nobleman, the Marquis d'Arlandes, made the first human free flight in history. They drifted over Paris for about 25 minutes in a Montgolfier balloon. Richard P. Hallion

Montgomery, *mahnt GUHM uh ree* or *muhn GUHM rih* (pop. 201,568; met. area 333,055), is Alabama's state capital and second largest city. Only Birmingham has more people. Montgomery is an agricultural center of the South. It is known as the *Cradle of the Confederacy.* Southerners established the Confederate States of America there in 1861, and the city was the first Confederate capital. It lies along the Alabama River in south-central Alabama (see **Alabama** [political map]).

Two towns—East Alabama and New Philadelphia—united in 1819 and formed a single city. The people named it Montgomery in honor of Brigadier General Richard Montgomery, a Revolutionary War hero.

Description. Montgomery, the seat of Montgomery County, covers about 133 square miles (344 square kilometers). Alabama State University, Faulkner University, Huntingdon College, and campuses of Auburn University and Troy State University are in Montgomery.

Tourist attractions include the State Capitol, the Montgomery Museum of Fine Arts, and the Old North Hull Street Historic District. The district, which lies near the Capitol, includes over 20 buildings from the 1800's. The First White House of the Confederacy is in Montgomery. It was the home of Jefferson Davis, who was president of the Confederacy. See **Alabama** (picture: State Capitol).

Government operations—on the federal, state, and local levels—and retail and wholesale trade have an important part in the city's economy. Government activities and trade each employ about 20 percent of the work force. Federal employers include nearby Gunter Air Force Station and Maxwell Air Force Base. Montgomery's chief industries include the manufacture of furniture, glass products, machinery, paper, and textiles.

Government and history. Montgomery has a mayor-council government. The mayor and the nine city council members are elected to four-year terms.

Alibamu and Creek Indians lived in what is now the Montgomery area before white settlers arrived. In 1817, a group led by Andrew Dexter of Massachusetts founded the town of New Philadelphia at the site of Montgomery. That same year, a group headed by General John Scott of Georgia established Alabama Town nearby. In 1818, Scott's group moved its town nearer to New Philadelphia and renamed its settlement East Alabama. After the two towns united and formed Montgomery in 1819, commerce and population increased.

The city became the state capital in 1846. Its population grew slowly but steadily during the late 1800's and early 1900's. It leveled off in the 1960's. Montgomery became a major steamboat landing and an important exporter of Alabama products, including cotton.

© Arvis D. Williams

The First White House of the Confederacy was in Montgomery, the capital of Alabama. Jefferson Davis lived here in 1861.

The civil rights leader Martin Luther King, Jr., lived in Montgomery and began his crusade there in 1955. In 1956, Montgomery became one of the first Southern cities to stop racial segregation on buses. See **King, Martin Luther, Jr.**

In 1973, the United States Army Corps of Engineers completed a project that included construction of three dams on the Alabama River. The dams enabled barges to travel on the river for the first time. This development helped increase trade in Montgomery. In 1985, workers completed a theater complex to house the Alabama Shakespeare Festival. The complex, situated in a large meadowland, includes two theaters; costume, scenery, and properties workshops; administrative offices; a cafe; and a gift shop. In 1989, a memorial to people who were killed in the civil rights movement in the United States was dedicated in Montgomery. David C. Weaver

Montgomery, *mahnt GUHM uh ree* or *mahnt GUHM ree,* **Bernard Law** (1887-1976), was a British Army commander in World War II. His victories in North Africa and Europe made him the idol of the United Kingdom.

Montgomery was born in London. He became an infantry lieutenant in 1908. At the outbreak of World War II in 1939, Montgomery was a major general. He took command of the Third Division and led it for nine months in France. He was rescued with his men from Dunkerque in May 1940 (see **Dunkerque**). Montgomery then commanded the defense zone of southeastern England, where he prepared defenses against an expected German invasion.

In 1942, Montgomery took charge of the Eighth Army in North Africa and restored its weakened morale. That October, he attacked German Field Marshal Erwin Rom-

United Press Int.

Lord Montgomery

mel's Afrika Korps at El Alamein, Egypt, and eventually drove the Germans into Tunisia.

After the African campaign, Montgomery took part in the invasion of Sicily and in early fighting on the Italian mainland. He then helped plan the invasion of France. Montgomery led the 21st Army Group that landed in Normandy in June 1944 and was promoted to field marshal in August.

After the war, Montgomery became head of the British zone of occupation in Germany. In 1946, he received the title Viscount Montgomery of Alamein in recognition of his war service. He served as chief of the British Imperial General Staff from 1946 to 1948, and then as chairman of the commanders in chief of the Western European Union from 1948 to 1951. Montgomery served as Deputy Supreme Allied Commander of the North Atlantic Treaty Organization (NATO) from 1951 to 1958.

Ian F. W. Beckett

Montgomery, *mahnt GUHM uh ree* or *mahnt GUHM ree,* **Lucy Maud** (1874-1942), was a Canadian author best known for her novel *Anne of Green Gables* (1908). The novel describes an adolescent girl's search for independence from the adult world. Montgomery based it on her childhood experiences living with her grandmother at Cavendish in the Canadian province of Prince Edward Island. The novel's lovable heroine and pleasing setting on Prince Edward Island gained Montgomery an international reputation. Montgomery described Anne's career and marriage in seven later novels.

Montgomery was born Nov. 30, 1874, in Clifton (now New London), Prince Edward Island. After attending Dalhousie University, she worked as a journalist and teacher in Halifax, Nova Scotia. She moved to Cavendish in 1898 to take care of her grandmother, who was ill. There, she began writing short stories and poems for children's magazines. Montgomery was awarded the Order of the British Empire in 1935. The Green Gables Farmhouse at Cavendish, believed to be the scene of Montgomery's famous novel, is now a national museum. See **Prince Edward Island** (picture). Rosemary Sullivan

Month. The calendar year is divided into 12 parts, each of which is called a *month.* But the word *month* has other meanings. Several kinds of months are measured by the moon's motion. At one point in the moon's path, it is closest to the earth. This point is called the *perigee.* The time the moon takes to revolve from one perigee to the next is an *anomalistic month.* This period averages 27 days, 13 hours, 18 minutes, and 33.1 seconds.

If the moon were looked at from a distant star, it would seem to make a complete revolution around the earth in 27 days, 7 hours, 43 minutes, and 11.5 seconds. This period is a *sidereal month.* The *proper lunar month,* which is called the *synodical month,* is the period between one new moon and the next, an average of 29 days, 12 hours, 44 minutes, and 2.8 seconds.

The synodical month is one of three natural divisions of time. The other two are the rotation of the earth on its axis, or a day, and the revolution of the earth around the sun, or a year. Another astronomical month is the *solar month,* which is one twelfth of a solar year. The solar month is the time taken by the sun to pass through each of the 12 signs of the zodiac (see **Zodiac**).

Our calendar months vary in length from 28 days to 31 days. The lengths of calendar months have no relation to astronomy. At first, the 12 months were 29 and 30 days alternately. Later, days were added to the months to make the year come out closer to a *solar year*—the time the earth takes to go once around the sun.

In the Gregorian calendar which we use today, each day of the month is called by its number. June 1 is the "first of June," and so on. The ancient Greeks divided the month into 3 periods of 10 days, and the French Revolutionary calendar used months of equal length divided into 3 parts of 10 days each. The fifteenth day of the month was called the fifth day of the second decade.

The Roman system was even more complicated. The Roman calendar had three fixed days in each month, the *calends,* the *nones,* and the *ides.* The Romans counted backward from these fixed days. They would say something would happen, for example, three days before the nones. The calends were the first day of the month. The ides were at the middle, either the 13th or 15th of the month. The nones were the ninth day before the ides, counting both days. When the soothsayer told Julius Caesar to "beware the Ides of March," he meant a very definite day. James Jespersen

See also the articles in *World Book* on each month of the year. See also **Calendar; Day; Moon** (The movements of the moon); **Ramadan.**

Monticello, *MAHN tih CHEHL oh* or *MAHN tih SEHL oh,* is the home Thomas Jefferson designed and built for himself on a hilltop just outside Charlottesville, Virginia. He started planning Monticello in 1768, and construction began in 1770. The first part was completed in 1775, but alterations and expansions continued until 1809.

In designing Monticello, Jefferson drew on his knowledge of local traditions, ancient Roman buildings, and especially the work of Andrea Palladio, an Italian architect of the 1500's. Palladio's Villa Rotonda near Vicenza, Italy, is the major source for Monticello's symmetrical plan and central dome. Jefferson also added several original and practical elements, such as a revolving desk and an enclosed bed that opened onto both his bedroom and study. William J. Hennessey

See also **Jefferson, Thomas** (picture).

Montmorency River, *MAHNT muh REHN see,* is a short, swift river in Quebec. It is named for the Duc de Montmorency, an admiral of France. The river rises in Snow Lake and flows southward for about 62 miles (100 kilometers). It empties into the Saint Lawrence River about 6 miles (10 kilometers) northeast of Quebec City. Montmorency Falls, which are about 150 feet (46 meters) wide and 251 feet (77 meters) high, lie at the mouth of the river. They are Quebec's highest waterfall.

Carman Miller

Montpelier, *mahnt PEEL yuhr* (pop. 8,035), is the capital of Vermont. It stands along the Winooski River in the central part of the state. For the city's location, see **Vermont** (political map).

The life insurance industry and the state government employ many of the city's people. Other industries include printing and the manufacture of plastics, machinery, and stone-finishing and sawmill equipment.

Montpelier has the smallest population of any state capital in the United States. Chartered in 1780, Montpelier became a city in 1895. It has a council-manager government. John McCardell

Montreal is the second largest city in Canada, after Toronto, and one of the largest French-speaking cities in the world. Many modern office towers stand in downtown Montreal.

Montreal

Montreal, *MAHN tree AWL,* is the second largest city in Canada, after Toronto, and the largest city in the province of Quebec. Montreal is also one of the world's largest French-speaking cities. More than half of Montreal's people speak French as their first language.

Montreal is a major center of Canadian education, culture, business, and industry. Since the 1940's, Toronto has gradually replaced Montreal as Canada's most important economic center. However, Montreal remains more important than Toronto in higher education.

The city of Montreal lies on an island and is built around a mountain. The Island of Montreal sits in the St. Lawrence River, near where the St. Lawrence and Ottawa rivers meet in southern Quebec. A tree-covered mountain, Mount Royal, rises 763 feet (233 meters) in the island's center. This mountain gave the city its name.

The name *Montreal* can refer to the city itself or the broader metropolitan area. The broader area, known as Greater Montreal, includes the city of Montreal and surrounding suburbs.

Montreal is a modern metropolis with office towers, universities, a casino, luxury shopping areas, a subway, deluxe hotels, professional sports teams, major museums, and glittering nightlife. Residents take pride in making the best of the sometimes fierce winter weather. Montreal's National Hockey League team, the Canadiens, has had one of the most successful histories of any team in professional sports. The city also is known for the fashion sense of *les montrealaises* (the women of Montreal).

Brian Kappler, the contributor of this article, is Political Editor at The Gazette *in Montreal.*

In 1535, the French explorer Jacques Cartier became the first European to reach the site that is now Montreal. Cartier climbed the mountain and named it Mont Réal (Royal Mountain, or Mount Royal). The first permanent European settlement on the site was established in 1642. That year, Paul de Chomedey, Sieur (Lord) de Maisonneuve—a former French Army officer—brought a small group of Roman Catholic missionaries and settlers to the island from France. The settlement was first called Ville-Marie (Mary's City) in honor of the Virgin Mary. But by the early 1700's, the town had become identified with the mountain and was called Montreal.

Today, Montreal faces challenges related to changes in its ethnic population. Many French-speaking people have moved to suburbs off the Island of Montreal, while many immigrants have moved into the city. As a result, there is social and political tension between people who welcome Montreal's growing ethnic diversity and people who wish to maintain the city's French character.

Tension also exists between Montreal and the rest of Quebec. Montreal has many immigrants, English speakers with ties to other Canadian provinces, and French Quebecers who also speak English. But the rest of Quebec remains deeply French in identity.

Montreal also faces problems common to other large cities. These problems include poverty, declining quality and availability of public services, drug abuse, criminal gangs, and pollution. However, Montreal has a reputation for being a safe, low-crime city.

The city

In 2000, the Quebec provincial legislature passed a law to combine the 28 municipalities on the Island of Montreal and some adjacent islands. This law, which

Vieux-Montréal (Old Montreal) is the city's historic district. Its streets are lined with many old stone buildings, charming stores and restaurants, and historic houses.

© Stephan Poulin, Tourism Montreal

took effect at the beginning of 2002, provides for one city of Montreal stretching over the entire area. The former city of Montreal covered 68 square miles (177 square kilometers). The enlarged city covers 193 square miles (500 square kilometers).

The Island of Montreal is triangular, measuring about 32 miles (51 kilometers) long and 10 miles (16 kilometers) wide at its widest point. It covers 191 square miles (495 square kilometers). Greater Montreal includes all of the Island of Montreal, Jésus Island to the north, several smaller islands, and parts of the Quebec mainland. The official Montreal metropolitan area covers 1,554 square miles (4,024 square kilometers).

The Montreal downtown area, called *le centre-ville* in French, lies between the St. Lawrence River and Mount Royal. A huge park covers the top of the mountain. The city's historic district, next to downtown and bordering the river, is called Vieux-Montréal (Old Montreal). Residential areas stretch away from downtown to the geographic north, south, and west.

Montrealers have an unusual way of describing directions in Montreal. For example, Boulevard St.-Laurent, one of Montreal's chief streets, is described by residents as running from south to north, away from the river. Geographically, however, this street runs more southeast to northwest. The lively, ethnic St.-Laurent divides east and west street addresses in Montreal.

Boulevard St.-Laurent was long considered the dividing line between the heavily *francophone* (French-speaking) east side and the more *anglophone* (English-speaking) west side. Geographically, the east and west sides are more nearly the northern and southern parts of the city. During the 1980's and 1990's, Montreal saw increases in immigration, private-car travel, and *bilingualism* (ability to speak two languages). Today, as a result, English, French, and other languages can be heard anywhere in Montreal.

The St. Lawrence River and the Lachine Canal have historically been important commercial and industrial corridors. The canal, which crosses the southern part of the Island of Montreal, served as a detour around the river's Lachine Rapids. Since about 1940, however, changes in technology and transportation have reduced heavy industrial activity along the river and the canal. While the river remains an important route for cargo vessels, the canal is no longer in use for commercial shipping. Homes, stores, and recreational areas are replacing old industrial structures along the waterways.

Downtown Montreal has several streets with special characteristics. The wide Boulevard René-Lévesque (formerly Dorchester Boulevard) crosses the heart of downtown Montreal and is known for its skyscrapers. The city's best-known skyscraper, commonly called Place Ville Marie, is one of Montreal's most respected office centers. *Place* is the French word for *square*. The building rises 615 feet (187 meters) and is laid out in the shape of a cross. The height and shape of the building have made it a city landmark.

Rue Ste.-Catherine, a block away from Boulevard René-Lévesque, is noted for its shops, restaurants, and theaters. The fashionable Rue Sherbrooke, two blocks away from Rue Ste.-Catherine, attracts many visitors to its luxurious antique shops and art galleries. *Rue* is the French word for *street*.

The city's harsh winter climate has led to the growth of the Cité Souterrain (Underground City). The Underground City is a network of passages beneath the downtown streets. Shops and restaurants line the passages,

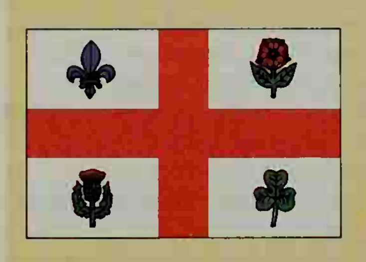
Montreal is in southern Quebec.

Facts in brief



Population: *City**—1,039,534. *Metropolitan area*—3,426,350.
Area: *City**—68 mi² (177 km²). *Metropolitan area*—1,554 mi² (4,024 km²).
Altitude: 187 ft (57m) above sea level.
Climate: *Average temperature*—January, 15 °F (-9 °C); July, 70 °F (21 °C). *Average annual precipitation* (rainfall, melted snow, and other forms of moisture)—40 in (102 cm). For information on the monthly weather in Montreal, see **Quebec** (Climate).
Government: Mayor-council. *Terms*—4 years for the mayor and the 73 council members.
Founded: 1642. Incorporated as a city in 1832.

*Figures are for the 2001 census. The city of Montreal now consists of 28 communities that merged on Jan. 1, 2002. The communities had a combined 2001 census population of 1,812,723. The city's post-merger area is 193 mi² (500 km²).

Largest communities in the Montreal area

Name	Population	Name	Population
Montreal	1,039,534	Saint-Hubert	75,912
Laval	343,005	LaSalle	73,983
Longueuil	128,016	Saint-Leonard	69,604
Montreal-Nord	83,600	Brossard	65,026
Saint-Laurent	77,391	Verdun	60,564

Symbols of Montreal. The city flag and the coat of arms of Montreal include the national flowers of France (fleur-de-lis), England (rose), Scotland (thistle), and Ireland (shamrock). Immigrants from these lands played important roles in the founding and growth of the city.

which link many public buildings and also provide access to several stations of the Métro, Montreal's subway.

Old Montreal borders the St. Lawrence River between Rue Berri and Rue McGill. Many of the old stone buildings of Old Montreal stand side by side with tall, modern structures. Charming restaurants, historic houses, and *boutiques* (small stores) line the area's narrow streets. Several of these streets are paved with cobblestones. Because Old Montreal has a European feel, producers often film movies and TV shows there. Old Montreal opens onto the Vieux-Port (Old Port), now a waterfront area of museums and other attractions.

© Thomas Kitchin, Tom Stack & Associates

The Cité Souterrain (Underground City) consists of stairways and passages beneath Montreal's downtown streets. Shops and restaurants line the passages, which link many public buildings.

Old Montreal has many reminders of Montreal's rich history. The city's oldest church, Notre-Dame-de-Bon-Secours, stands on Rue St.-Paul in Old Montreal. This Roman Catholic stone chapel was built in 1771 on the foundations of an earlier church. The St. Sulpice Seminary is on Rue Notre-Dame. Also known as the Vieux-Séminaire (Old Seminary), it is the oldest building in Montreal. Ville-Marie's first priests opened it in 1685, and priests have lived in the building ever since.

Two historic squares are near the seminary. Across Rue Notre-Dame is Place d'Armes (Parade Ground). The first clash between Ville-Marie's founders and the Iroquois Indians took place there in 1644. The Maison-

The Métro, Montreal's subway system, opened in 1966. Brightly colored mosaics decorate many Métro walls. The Métro has been called "the largest underground art gallery in the world."

Montreal

The small map shows the Montreal area. The large map shows downtown Montreal.

WORLD BOOK maps

neuve Monument in the square honors the city's founder. Also near the seminary, on Rue St.-Paul, is Place Royale (Royal Square). This square was the site of Fort Montreal, built by Ville-Marie's pioneers in 1642.

Bank and insurance company offices border Place d'Armes. The area also has several government buildings, including courthouses and Montreal's Hôtel de Ville (City Hall). The city's large, modern Palais des Congrès (Convention Centre) stands where Old Montreal merges into downtown.

Metropolitan area. Greater Montreal is Canada's second largest urban area. Only the Toronto metropolitan area is larger. Montreal's largest suburbs by population are Longueuil, on the south (geographic east) shore of the St. Lawrence; and Laval, on Jésus Island.

People

Montrealers call themselves *francophone, anglophone,* or *allophone,* depending upon whether their main language is French, English, or another language. The Island of Montreal is more than half francophone. Signs posted throughout the city appear mainly in French, the official language of the province of Quebec. Approximately half of Montreal's people speak both French and English. About 30 percent of the city's people speak only French, and about 13 percent speak only English.

Since the mid-1900's, hundreds of thousands of immigrants have settled in Montreal. Today, immigrants make up about a fourth of the city's people and almost a fifth of the metropolitan population.

Ethnic groups. More than half of Montreal's people have French ancestry. The city has well-established Italian, Greek, Jewish, and black communities. During the late 1900's, many people came to the city from South America, Africa, South Asia, Haiti and other parts of the West Indies, Lebanon and other Middle Eastern countries, China, Vietnam, and Portugal. Today, a stroller can often hear four or five languages on a single block in Montreal. More than 25 percent of Montrealers are descended from more than one ethnic group.

Religion. A large majority of Montreal's people are Roman Catholics, and most of the Catholics are of French descent. Historically, the Roman Catholic Church has strongly influenced Montreal public affairs and public opinion, especially among French speakers. However, the church's power has declined since about 1940. The majority of English-speaking Montrealers are Protestants. Anglicans and Presbyterians form the city's largest Protestant denominations. Jews make up another large religious group in Montreal.

Housing. Most Montrealers rent their dwellings. Because many leases expire at the end of June, Montrealers often find themselves moving into new living spaces on Canada Day, Canada's national day on July 1. Greater Montreal has a lower proportion of homeowners and a higher proportion of tenants than any other Canadian metropolitan area. However, rapid suburban growth since about 1970 has made home ownership more common, especially off the Island of Montreal.

Two- or three-story apartment buildings with outside staircases are a common sight in the city of Montreal. Buildings in this style, constructed chiefly during the 1920's and 1930's, were designed to make maximum use of inside space. Row houses—rows of similarly designed dwellings that share common walls—also are common in the city. Many row houses, especially on the east side, have winding exterior staircases, often in black wrought iron.

Montreal is the site of one of the most unusual apartment developments in the world. This development, known as Habitat, stands on Cité du Havre, a strip of land that extends into the St. Lawrence River. Designed by Canadian architect Moshe Safdie, Habitat consists of 158 apartments that look like a stack of concrete boxes. The roof of one apartment serves as the terrace of another.

Montreal's city government strives to ensure decent housing, even in the poorest neighborhoods. The city has long had generous programs to help landlords make repairs and improvements. The city also spends a significant amount on "social housing," a local term describing tax-supported rent for the poor.

Education. Until 1998, the public school system in Montreal was organized on the basis of language and religion. There were four kinds of schools within the public school system. They were: (1) Roman Catholic schools that taught entirely in English, (2) Roman Catholic, French-language schools, (3) Protestant, English-language schools, and (4) Protestant, French-

Barbara K. Deans

Balconies and outdoor staircases are a distinctive feature of many apartment buildings in the city. Montreal has a higher proportion of renters than any other Canadian metropolitan area.

language schools. But in 1998, school systems across Quebec were reorganized on the basis of language only. In Montreal, three school boards administer French-language schools, and two school boards administer English-language schools. Montreal also has numerous religious and nonreligious private schools.

Montreal is the home of two internationally known research universities, the University of Montreal and McGill University. Courses at the University of Montreal are taught in French, and courses at McGill are conducted in English. Montreal's other institutions of higher learning include Concordia University, an English-language university; and the University of Quebec at Montreal, which teaches in French. Specialized business and engineering schools also operate in Montreal.

Social problems. Montreal faces many familiar urban problems. One of these problems is poverty. Montreal ended the 1900's with a rapidly growing economy, and the city has a well-educated work force. But Montreal also attracts thousands of jobseekers from rural Quebec, some of whom lack necessary skills or training. As a result, many people live in Montreal with little income other than public assistance.

Beginning in the early 1970's, higher-income people, particularly francophones, began moving away from the Island of Montreal into off-island suburbs. As a result, lower-income people and immigrants became a higher proportion of Montreal's population.

In 1974, the Quebec government made French the official language of the province. In 1976, the Parti Québécois (PQ), which favors Quebec's independence from Canada, first gained control of the provincial legislature. The PQ has been in and out of power since then. These political developments have created tension between francophones and anglophones in Montreal and the rest of Quebec. Many English-speaking people, and some important companies that conduct business in English, have left Montreal and Quebec rather than switch to French.

Cultural life

Montreal is one of North America's leading cultural centers. It has outstanding dance, drama, and musical groups, and its art galleries and museums rank among the finest in Canada. The city is also known for its many beautiful churches and well-planned parks. Montreal's sports attractions include professional baseball, football, and hockey.

Each year, millions of tourists visit Montreal. Many restaurants in Montreal specialize in French cooking. Visitors can also find restaurants featuring a wide variety of other ethnic foods.

The arts. The world-famous Montreal Symphony Orchestra and the Montreal Metropolitan Orchestra make their home in the city. Other musical organizations in Montreal include I Musici, Musica Camerata Montreal, and the Montreal Baroque Orchestra. Montreal also has Les Grands Ballets Canadiens, a major ballet company; several jazz dance companies; and a number of French-language theater groups, including Le Théâtre du Nouveau Monde, Le Théâtre du Rideau Vert, and Le Théâtre Jean Duceppe. The Centaur Theatre features English-language productions.

Summer is "festival season" in Montreal. Cultural events, performances, and shows run almost nonstop from June through August, drawing thousands of people downtown. The major festivals include the International Jazz Festival, the World Film Festival, and the Just for Laughs/Juste pour Rire comedy festival.

Place des Arts at Rue Ste.-Catherine and Rue St.-Urbain is one of North America's finest centers for the performing arts. The center includes the Salle Wilfrid-Pelletier concert hall, which can seat 3,000 people. The center also houses the smaller Maisonneuve and Port-Royal theaters, both of which offer stage productions.

Libraries. The public library system in the city of Montreal consists of a main library and many branches. The system's most important books and other items are in French. But English-language collections and items in other languages are also available. Other libraries in Montreal include the Fraser-Hickson Library, the Jewish Public Library, the Quebec National Library, and the libraries of the city's four universities.

The Quebec government plans to build a major provincial library at Rue Berri and Boulevard de Maisonneuve. The new library is scheduled to open in 2003.

Museums. The downtown Musée des Beaux-Arts (Museum of Fine Arts) is Montreal's principal museum. It hosts major traveling exhibitions and also has a permanent collection of 25,000 objects. These items include major European works, Inuit art, other Canadian works, Asian and South American pieces, and collections of furniture, glass, lace, and silver. Founded in 1860, it is one of Canada's oldest museums.

The Centre Canadien d'Architecture (Canadian Centre for Architecture) includes a museum, library, and conference center focusing on architecture past and present. The city also has a Musée d'Art Contemporain (Museum of Contemporary Art) and a planetarium.

The Château Ramezay, in Old Montreal, dates from 1705. It was once the home of Claude de Ramezay, the second French governor of Montreal. The building has been a history museum since 1895. Other important history museums are the McCord Museum of Canadian History; the David M. Stewart Museum; and the Musée Pointe-à-Callière, which focuses on the city's early history and archaeological findings.

Churches. Montreal is famous for its more than 300 churches. Several are noted for their Gothic-style architecture. St. Patrick's Church, in downtown Montreal, serves English-speaking Roman Catholics. Basilique Notre-Dame (Notre Dame Basilica), in Old Montreal, is attended by French-speaking Catholics. This church has two towers, one of which houses a huge bell. This bell, called Le Gros Bourdon (the Great Bell), weighs 12 tons (11 metric tons). Notre Dame Basilica is also noted for its magnificently carved wooden interior.

Notre-Dame-de-Bon-Secours is a well-known chapel in Old Montreal. Some Montrealers call it the Sailors' Church. A statue of the Virgin Mary on the roof was once believed to perform miracles to help sailors.

The Basilique-Cathédrale Marie-Reine-du-Monde (Cathedral-Basilica of Mary, Queen of the World) stands in the heart of downtown Montreal. The designers of this church patterned it after St. Peter's Basilica in Vatican City. The church serves as the seat of the Catholic archdiocese of Montreal. The seat of the Anglican diocese, Christ Church Cathedral, is also downtown. St.

Place des Arts is one of the finest performing arts centers in North America. The center includes a concert hall that can seat 3,000 people.

Joseph's Oratory stands on the west slope of Mount Royal. Every year, hundreds of thousands of people visit this Roman Catholic shrine. The dome of the shrine is a major landmark.

Parks. Montreal has hundreds of parks and recreation areas. Mount Royal Park covers 494 acres (200 hectares) on the mountain. The park was designed by Frederick Law Olmsted, who designed New York City's Central Park. Mount Royal Park includes Beaver Lake, a popular spot for ice skating during the winter. Mount Royal also has lookout spots that offer visitors magnificent views of the Montreal area. An iron cross rises about 100 feet (30 meters) on the mountain's east side. The cross, illuminated at night, is a memorial to Ville-Marie's survival of a flood in 1642.

A world-class Jardin Botanique (Botanical Garden) lies in Montreal's east end near the Olympic Stadium. This vast attraction features gardens with various themes, including the Chinese Garden, the Japanese Garden, and the Rose Garden. Also on the Botanical Garden grounds is the Montreal Insectarium, which displays thousands of live and mounted insects.

Another large park, Parc Jean-Drapeau (formerly Parc des Îles), covers Île Ste.-Hélène and Île Notre-Dame. These two islands lie in the St. Lawrence River south (geographically east) of the Island of Montreal. Parc Jean-Drapeau includes numerous green spaces, the Montreal casino, and La Ronde amusement park, open during the summer months. La Ronde stands on the site of Expo 67, a world's fair held in Montreal in 1967.

Basilique Notre-Dame (Notre Dame Basilica) is noted for its magnificent interior.

© Bernard Boutrit, Woodfin Camp, Inc.

The Musée d'Art Contemporain (Museum of Contemporary Art) has a permanent collection of about 6,000 works of art, including paintings and sculptures. The museum is popular with both children and adults.

Sports. The Montreal Canadiens of the National Hockey League have won more Stanley Cup championships than any other team in professional hockey. Montreal is also the home of the Montreal Expos baseball team of the National League and the Montreal Alouettes of the Canadian Football League.

Winter sports are a major attraction in the Montreal area. Cross-country skiers and tobogganers rush to Mount Royal after a snowfall. Downhill skiing is popular in the nearby Laurentian Mountains and Eastern Townships.

Economy

Montreal is one of Canada's chief transportation centers. It is the second most important Canadian city in finance and industry. Only Toronto is more important. In addition, Montreal lies in the most fertile and productive agricultural region of Quebec. As a result, the city has become a food-processing center.

Montreal's economy was once controlled by private companies that used English as the language of business. As a result, Montrealers needed a good knowledge of English to obtain a well-paying job. Since 1977, however, the Quebec government has required all companies that employ 50 or more people to use French as the language of business.

Transportation. The St. Lawrence River links Montreal with the Atlantic Ocean, about 1,000 miles (1,600 kilometers) to the northeast. The St. Lawrence Seaway extends shipping services about 1,300 miles (2,100 kilo-

meters) inland. It makes Montreal a major stopover point for ships sailing between the Great Lakes and the Atlantic (see **Saint Lawrence Seaway**).

The Port of Montreal, also called Montreal Harbour, stretches 15 miles (24 kilometers) along the north (geographic west) bank of the St. Lawrence River. It serves oceangoing, coastal, and inland vessels and handles about 23 million tons (21 million metric tons) of cargo yearly. This amount includes about 2 $\frac{1}{5}$ million tons (2 million metric tons) of grain.

Montreal ranks as one of Canada's largest railroad centers. Canadian National Railway, a transcontinental rail line, has its headquarters in the city. This railroad carries freight east to the Atlantic seaboard and west to the Pacific Coast. Several railways connect Montreal and cities in the United States.

Major airlines use Montreal International Airport (Dorval), which lies in the western part of the Island of Montreal. Montreal International Airport (Mirabel), northwest of the island, handles mainly air freight. Air Canada, the nation's largest commercial airline, has its headquarters in the city. The International Civil Aviation Organization, a specialized agency of the United Nations, also has its headquarters there.

Several major highways serve Montreal. The Trans-Canada Highway, which runs from coast to coast, crosses the Island of Montreal. Nearly 20 railroad and highway bridges connect the island with Laval and the south (geographic east) shore of the St. Lawrence River.

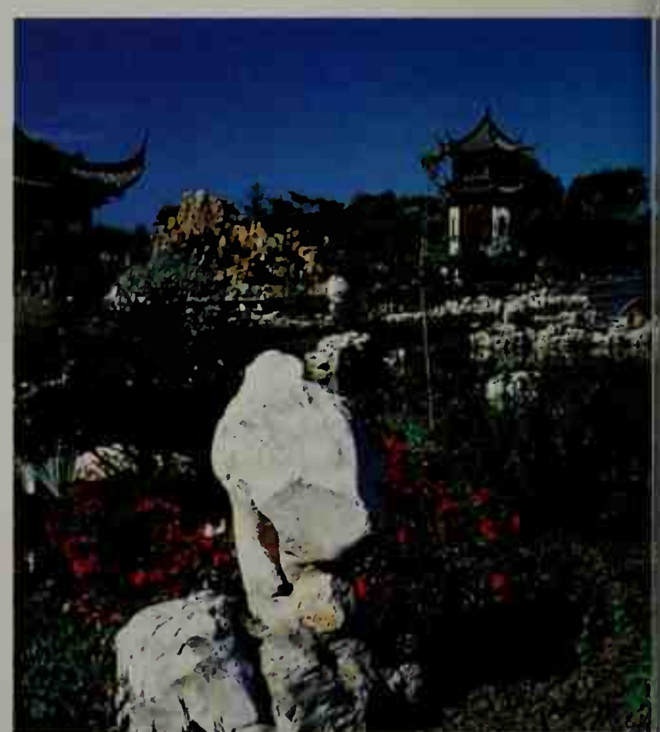
A subway system called the Métro, buses, and commuter trains provide public transportation on the Island of Montreal. The Métro, which opened in 1966, was the first subway in the Western Hemisphere to use cars with rubber tires. Brightly colored mosaics and architectural designs decorate many Métro walls. Because of these decorations, the Métro has been called "the largest underground art gallery in the world."

Industry. Manufacturing is a leading source of employment in Greater Montreal. The more than 5,000 factories in the area employ about a fourth of its workers. These plants account for about two-thirds of Quebec's industrial production.

Greater Montreal's leading industries include the manufacture of aircraft and parts, the manufacture of telecommunications equipment, and food processing. The area's chief food products are beer, canned goods, and sugar.

Greater Montreal is also one of Canada's major centers for the manufacture of chemicals, clothing, and tobacco products. Pharmaceuticals are an important chemical product. Petroleum refineries in Montreal produce much of Canada's gasoline. Montreal's historic fur industry still thrives, as do newer firms that produce computer software and other high-technology products.

Trade and finance. Companies in Greater Montreal play an important role in Canada's international trade. Montreal's bilingual culture gives it special access to French and other European trade.



Companies engaging in wholesale and retail trade within Canada employ many people in Greater Montreal. Wholesale companies sell goods to retail stores, while retail companies sell goods to consumers. Area retail stores include some of Canada's largest department stores. Place Bonaventure, in downtown Montreal, is one of the largest commercial buildings in the world. It has more than 3 million square feet (300,000 square meters) of space.

Montreal has branches of all of Canada's government-

Hockey fans watch the Montreal Canadiens of the National Hockey League play. The Canadiens have had one of the most successful histories of any team in professional sports. Hockey is the most popular sport in Montreal and the rest of Canada.

Montreal Botanical Garden

The Chinese Garden is one of several specialty theme gardens in Montreal's vast Jardin Botanique (Botanical Garden). The Jardin Botanique is among the most noted botanical gardens in the world. It also serves as the site of the Montreal Insectarium.

approved banks. Two of these banks, the Banque Nationale and Laurentian Bank, are based in Quebec. Banks, credit organizations, savings firms, and other financial companies in the area employ many people. Loans by these companies contribute to the growth of business and industry throughout Canada. The Bank of Montreal, which was founded in 1817, was the first bank in Canada.

The Montreal Exchange, Canada's first stock market, opened in the city in 1874. As a result of the reorganization of Canadian stock markets in 1999, major stock trading no longer takes place on the Montreal Exchange. The exchange, now called the Bourse de Montréal, instead specializes in the buying and selling of investment contracts called *derivatives.*

Communication. Four daily newspapers are published in Montreal. Three of these newspapers—*La Presse, Le Devoir,* and *Le Journal de Montréal*—are written in French. *The Gazette* is the only Montreal daily in English. *Le Journal de Montréal* has the largest circulation of any of Quebec's daily newspapers. *The Gazette,* founded in 1778, was the first newspaper published in Montreal.

Several radio and television stations broadcast from the city, about half of them in French and half in English. Station CFCF of Montreal was Canada's first radio station. It began broadcasting in 1919. Radio-Canada, the French-language network of the Canadian Broadcasting Corporation (CBC), is based in Montreal. More French-language TV programs are produced in Montreal than in any other city in the world except Paris. Television station CBFT, one of the first two Canadian stations, began broadcasting from Montreal in 1952. The other pioneer station was CBLT of Toronto.

Government

The city of Montreal has a mayor-council form of government. Voters elect the mayor and the 73 City Council members to four-year terms. The mayor acts as the administrative head of the city government. He or she supervises the various city departments. The City Council passes the city's ordinances. It also appoints and dismisses directors of city departments and adopts the annual city budget.

In 2000, the Quebec legislature passed a law to combine the 28 municipalities on the Island of Montreal and some adjacent islands. This law, which took effect on Jan. 1, 2002, provides for one city of Montreal stretching over the entire area. The city is divided into 27 *boroughs* (divisions) based partly on the boundaries of the former city of Montreal and its suburbs. Each borough has at least one representative on the City Council. In addition to the City Council, there are also 27 borough councils that have responsibility for matters within each borough. These responsibilities include local roads and recreational facilities.

More than 40 percent of the city of Montreal's revenue comes from taxes on property. The rest of the city's funds come from taxes on businesses, water, and amusements, and from aid given by the province.

Like most other big cities, Montreal has difficulty finding ways to pay for the rapidly rising costs of government services. The major problems faced by Montreal's government include building more low-cost housing and maintaining the city's *infrastructure* (public services and facilities).

History

Algonquin and Iroquois Indians lived in the Montreal region before European settlers arrived. The area's rivers and lakes provided the Indians with a plentiful supply of fish. The waterways also served as excellent transportation routes.

Exploration. In 1535, the French explorer Jacques Cartier sailed up the St. Lawrence River. The Lachine Rapids, geographically south of what is now Montreal, prevented Cartier from going farther by ship. He then explored the Island of Montreal and found the Iroquois village of Hochelaga at the foot of Mount Royal. Several thousand Indians lived in the village.

Another famous French explorer, Samuel de Champlain, visited the site of Montreal in 1603 and 1611. By that time, the Iroquois had abandoned the site.

French settlement. In 1639, Jérôme Le Royer, Sieur de la Dauversière, a French tax collector, formed a company in Paris to establish a colony on the Island of Montreal. In 1641, the company sent a Roman Catholic missionary group to the island to convert the Indians to Christianity. The group, led by Paul de Chomedey, Sieur de Maisonneuve, arrived in 1642. The colonists built a fort at what is now Place Royale in Old Montreal and established the settlement of Ville-Marie.

Iroquois Indians attacked the colony, hoping to stop the profitable fur trade that the French had established with the Algonquin and Huron. The Algonquin and Huron were the chief rivals of the Iroquois. Despite the attacks, the colony prospered as a religious center and fur-trading post. The French and the Iroquois made peace in 1701.

By the early 1700's, Ville-Marie had become known as Montreal. It had a population of about 3,500 in 1710 and ranked as the commercial heart of France's North American empire, which was called New France. Montreal's location on the St. Lawrence River made it an important center of trade. European goods passed through Montreal on the way to the North American west. Fur traders shipped pelts from Canada's interior to Europe by way of Montreal.

British settlement. British troops under General Jeffery Amherst captured Montreal in 1760, during the French and Indian War (1754-1763). The surrender of Montreal marked the end of the fighting in this war and led to the collapse of New France. The Treaty of Paris, signed in 1763, officially ended the French and Indian War and made Canada a British colony. A few English-speaking settlers then came to Montreal.

General Richard Montgomery's American forces occupied Montreal in November 1775, during the Revolutionary War in America (1775-1783). Benjamin Franklin and other American diplomats tried to gain French-Canadian support against the British. But their efforts failed, partly because most French Canadians regarded the war as just a quarrel between Britain (now the United Kingdom) and its colonies. In June 1776, the arrival of British troops forced the American soldiers to withdraw, and Montreal became a British possession again.

Fur traders in Montreal founded the North West Company as a rival to the Hudson's Bay Company fur

Lithograph (1843) by James Duncan; Public Archives of Canada

Montreal's waterfront district was the city's chief center of activity in the early 1800's, *shown here.* Today, the district is known as Old Montreal and has many historic sites.

trade. The new firm was first organized in the 1770's.

Montreal began to expand on the Island of Montreal in the late 1700's. English-speaking merchants began to establish businesses in Montreal during this period. They gradually gained control of the town's economy, in part because many French merchants had returned to France after British troops captured the city in 1760.

The early 1800's. By 1800, Montreal's population had reached 9,000. Canada's first steamboat, the *Accommodation,* sailed the St. Lawrence River from Montreal to the city of Quebec in 1809. In 1821, the Hudson's Bay Company bought the North West Company. The Hudson Bay area then became the chief market for furs, and Montreal declined as a fur-trading center.

The Lachine Canal, which crosses the southern edge of Montreal, opened in 1825. It provided a detour for small vessels around the river's Lachine Rapids and led to a sharp increase in trade and travel between Montreal and the Great Lakes. Shipping replaced fur trading as Montreal's chief industry, and Montreal grew in importance as a port.

In 1832, Montreal was incorporated as a city. From 1844 until 1849, it served as the capital of the Province of Canada. By 1850, the city's population had soared to about 50,000. For a short period, the majority of Montreal's population was English-speaking.

The growing city. Montreal continued to develop as a transportation center during the mid-1800's, when railways linked it to areas west of Toronto and to Portland, Maine. Investment by wealthy English-speaking merchants helped Montreal become a major industrial center during this period. Many industries were built along the Lachine Canal. Thousands of British immigrants, and French Canadians from other parts of Quebec, came to Montreal to find jobs in the new factories. By 1871, about 107,000 people lived in Montreal. About half of these people were of French ancestry.

The Canadian Pacific Railway Company, based in Montreal, completed Canada's first transcontinental railroad in 1885. The railroad attracted more industry and brought new prosperity to the city. By 1901, Montreal's population had risen to about 268,000. The *annexation* (addition) of several neighboring communities helped it reach about 468,000 by 1911.

The war issue. During World War I (1914-1918), Canada fought on the side of the Allies, which included France, the United Kingdom, and the United States. Some French Canadians in Montreal supported the government's policy and volunteered for the war, as did many of the city's English-speaking citizens. But many French Canadians, feeling little loyalty to the United Kingdom, took almost no interest in the war. In 1917, Canada's government introduced a military draft, also known as *conscription.* Many French Canadians opposed this policy.

During World War II (1939-1945), conscription again caused unrest among French Canadians. In 1940, Montreal Mayor Camillien Houde urged Montrealers to defy a Canadian government plan to register the country's men for possible military service. Houde charged that the registration would lead to a military draft for overseas service. Most French Canadians opposed a draft, and Canadian government leaders had pledged not to establish one. Federal authorities arrested Houde and kept him in a prison camp until 1944. Tensions increased when the Canadian government introduced a draft for overseas service in 1944.

The changing city. By the early 1950's, Montreal's population had topped 1 million. During the late 1950's, the city entered a period of great economic growth. In 1958, a city development program enlarged Montreal Harbour. The opening of the St. Lawrence Seaway in 1959 attracted hundreds of industries.

During the 1960's, a construction boom in downtown Montreal gave the city a new skyline. Private developers tore down old structures throughout the area and re-

placed them with huge banks, hotels, and office buildings. Important downtown developments during this period included the Place Ville Marie and Place Victoria skyscrapers; Place Bonaventure, a trade mart; and Place des Arts, a cultural center. An underground shopping network was also constructed.

The city built new highways and a new subway, the Métro, to help serve visitors attending Expo 67, a world's fair held in Montreal in 1967. More than 50 million people attended the exhibition.

In 1975, the Montreal International Airport (Mirabel) opened. Montreal hosted the 1976 Summer Olympic Games. Construction for the event included housing for the athletes and a new sports stadium. Montreal officials began to rent the housing to the public in 1978. Jean Drapeau, the city's longest-serving mayor, held office from 1954 to 1957 and again from 1960 until 1986.

The separatist movement. In 1960, the Rassemblement pour l'Indépendence Nationale (Assembly for National Independence) was founded in Montreal. Its chief aim was to bring about the separation of Quebec from the rest of Canada and make the province an independent nation.

The Front de Libération du Québec (Quebec Liberation Front), a terrorist organization, began to use violence to promote separatism in 1963. At first, the FLQ attacked armories and other symbols of the federal government. The organization soon became involved in labor disputes. During the period from 1963 to 1968, the FLQ claimed responsibility for bombings and armed robberies in the Montreal area.

In October 1970, members of the FLQ kidnapped British Trade Commissioner James R. Cross and Quebec Labor Minister Pierre Laporte. Canadian Prime Minister Pierre Trudeau, a French Canadian born in Montreal, sent federal army troops to Montreal and other Quebec cities to guard government officials. The murder of Laporte later in the month increased tension in Montreal. Federal troops withdrew in January 1971, after police arrested four members of the FLQ and charged them with the kidnapping and murder of Laporte. Cross's kidnappers had released him after government officials guaranteed the kidnappers safe passage to Cuba.

In 1977, Quebec's government passed a law that required all companies with 50 or more employees to use French as the language of business. As a result, several major corporations based in Montreal that had primarily used English in the course of business left the city.

The late 1900's. In 1982, Montreal annexed the northern suburb of Pointe-aux-Trembles. This annexation increased the area of Montreal by about 10 percent. Development of downtown Montreal continued in the 1980's and 1990's. The Old Port area was developed for recreation and tourism during this period.

In the 1980's and 1990's, the focus of Montreal's economy changed greatly. Old manufacturing plants closed, and new high-technology companies moved into the city. Montreal's unemployment rate, which has often been high, dropped in the late 1990's as high-technology firms competed for skilled workers.

Recent developments. In 2000, the Quebec legislature passed Bill 170, a law to merge the 28 municipalities on the Island of Montreal and some adjacent islands. This law, which took effect at the beginning of 2002, provides for one city of Montreal stretching over the entire area.

Questions

What is the largest ethnic group in Montreal?
Why did the Iroquois Indians attack Ville-Marie in the 1600's?
Montreal's public school system is organized on what basis?
Who founded Montreal? When?
The design of the Cathedral-Basilica of Mary, Queen of the World, is patterned after what other church?
In what ways has the population of the city of Montreal changed since the 1970's?
What have been some of the consequences for Montreal of the French language law passed by the Quebec provincial legislature in 1974?
Why has the Métro been called the "world's largest underground art gallery"?
What is Habitat? Who designed it?
What is Montreal's Underground City?

Montreal, University of, or Université de Montréal, is a private, coeducational university in Montreal. All courses are taught in French. They lead to bachelor's, master's, and doctor's degrees. The university has faculties of architecture, arts and science, business administration, dentistry, education, engineering, graduate

University of Montreal

The University of Montreal, the largest French-language university outside France, stands on the slopes of Mount Royal.

studies, law, medicine, music, nursing, optometry, pharmacy, physical health and education, theology, and veterinary medicine. It also offers interdisciplinary studies. The faculty of continuing education conducts evening and summer courses.

A large computer center serves all university departments. Research is conducted in all fields of study, especially in the medical, natural, physical, and social sciences. The university includes the Polytechnic School, or École Polytechnique; and a business school, the École des Hautes Études Commerciales.

The University of Montreal was founded in 1876. The university was controlled by the Roman Catholic Church until 1967, when it became nondenominational.

Monts, *mawn,* **Sieur de** (1560?-1630?), was a French explorer and colonizer who settled the region of Acadia in Canada. King Henry IV of France made de Monts a lieutenant general and the governor of Acadia. The king also granted de Monts a monopoly over the fur trade in Acadia on the condition that he bring settlers to the region.

De Monts sailed for America in March 1604 with Jean de Biencourt de Poutrincourt and Samuel de Champlain. They explored the Bay of Fundy and settled at the mouth of the Saint Croix River. In 1605, they founded Port Royal, Nova Scotia. De Monts then returned to France, leaving Poutrincourt as governor.

De Monts never returned to Canada. His monopoly over the fur trade ended in 1608. But he remained active in the trade until 1617. In 1608, de Monts sent Champlain to Canada to found Quebec, establish a warehouse, and explore the country. De Monts was born in Saintonge, France. His given and family name was Pierre du Gua.

John A. Dickinson

Montserrat, *MAHNT suh RAT,* is one of the Leeward Islands in the West Indies. It is an overseas territory of the United Kingdom. It lies about 250 miles (402 kilometers) southeast of Puerto Rico (see **West Indies** [map]). Montserrat has an area of 39 square miles (101 square kilometers). Montserrat has three groups of mountains. The highest group is the Soufrière Hills, which rise to about 3,000 feet (910 meters) in the southern part of the island.

Christopher Columbus reached Montserrat in 1493 and named the island after a mountain in Spain. Irish settlers came to Montserrat in 1632, and today many of the people speak with a *brogue* (Irish accent). Britain has controlled the island since 1783. In 1989, Hurricane Hugo struck Montserrat, severely damaging most of its buildings. In 1995, a volcano in the Soufrière Hills began a series of eruptions. In 1996, the capital, Plymouth, was evacuated. Today the city is covered in rock and ash. After the eruptions began, thousands of Montserrat's people were moved into temporary shelters in the northern part of the island or were evacuated to neighboring islands. Prior to the evacuations, Montserrat had a population of about 13,000. Some people who were evacuated have since returned to the island. Gerald R. Showalter

Montserrat, *MAHNT suh RAT,* is a famous Benedictine monastery about 30 miles (48 kilometers) northwest of Barcelona, Spain. It is in a scenic mountainous area, also called Montserrat. The monastery was established about A.D. 1025. Its great treasure is the Black Virgin, a figure of the Virgin Mary said to have been carved by Saint Luke and brought to Spain by Saint Peter about A.D. 30. The small black wooden figure is one of the most sacred images in Spain. It is known as Our Lady of Montserrat, Patron of Catalonia.

The area's spectacular and rugged peaks, spires, and deep ravines inspired the original Latin name, *mons serratus* (notched or saw-toothed mountain). The name became *monte serrado* in Spanish and *Montserrat* in the Catalan language of the region. Leland M. Roth

Monument is a structure, usually a building or statue, built in memory of a person or an event. *National monuments* are places of historic, scientific, or scenic interest set aside by a government as public property. They include such structures as historic forts and such natural features as canyons. For a list of national monuments that have separate articles in *World Book,* see **National Park System** (table). William J. Hennessey

Mood is a person's state of mind or outlook on life. Everyone's mood may change from day to day, or, sometimes, from hour to hour. But in certain mental illnesses, usually called *bipolar disorder* or *manic-depressive disorder,* the patient's mood is obviously disturbed. Patients may be sad, or happy and excited, for no visible reason. Their mood changes often. Some psychiatrists believe that the basic trouble with such patients is a disturbance of their mood. They have suggested calling such illnesses *primary mood disturbances.* Psychoanalysts believe that an apparently unexplainable mood can be caused by unconscious thoughts, wishes, or guilt feelings. But there are as yet no data to prove this belief.

Paula J. Clayton

Mood, or *mode,* is a term applied to verb forms that distinguish among certain kinds of meaning. For example, the verb *is* in "He is my brother" is an *indicative* mood form—that is, it states a fact. But the verb *were* in "if he were my brother" is a *subjunctive* mood form—that is, it expresses a condition contrary to fact.

Some languages have elaborate mood forms, but in English not many contrasts remain between the indicative and the subjunctive mood. For the verb *be,* the indicative forms of the present tense are *I am, you are, he is, we are,* and *they are.* The subjunctive forms are *I be, you be, he be, we be,* and *they be.* In the past tense, the indicative forms are *I was, you were, he was, we were,* and *they were,* and the subjunctive forms are *I were, you were, he were, we were,* and *they were.* Other

verbs have a distinction at only one point: the third person singular of the present tense. For instance, *she calls* is indicative, but *she call* is subjunctive.

Subjunctive uses. Although the subjunctive has limited forms and uses in English, it is useful as a way of expressing a wish, a request, urgency, or a condition contrary to fact:

I wish it *were* true. (wish)
She asked that we *be* admitted. (request)
It is necessary that he *stay*. (urgency)
If words *were* deeds, we would be finished. (condition contrary to fact)

Older English usage employed the present subjunctive frequently in clauses introduced by *if* and *though*, such as "If it *be* he, let him be admitted," and "Though she *call* repeatedly, I shall not answer."

Other older uses of the subjunctive survive in many expressions, most of which are blessings or prayerful wishes: *God bless you, Long live the king, Heaven forbid, Suffice it to say,* and *God be with you.*

Imperative mood. The term *imperative mood* is commonly given to verbs that express commands or requests. "*Stop* the music," "*Leave* the room," and "*Give* this to your mother" are examples. In English, the imperative form is the *base* (simple) form of the verb. Imperative sentences usually have no subjects, and the omission of the subject is one of the chief signals that the sentence is a command or a request. But sometimes, imperative sentences do have subjects, as in "You do it, George."

Verb phrases. The terms *mood* and *mode* are also applied sometimes to verb phrases like *might go, should stay,* and *may try.* Words like *may, might, should,* and *would* are often called *modal auxiliaries.* They express the same meanings conveyed by mood endings on the verb in such languages as Greek or Latin. In English, however, modern grammarians usually limit the term *mood* to the indicative, subjunctive, and imperative forms, omitting the modals. William F. Irmscher

Moodie, Susanna (1803-1885), was a Canadian author. Her best-known book is her autobiography, *Roughing It in the Bush* (1852). The book gives an accurate account of the hardships of pioneer life in Canada in the 1830's. But it also includes humorous stories and lively sketches of people living on the Canadian frontier. Moodie based the book on her experiences as a pioneer farmer in what is now Ontario.

Moodie was born into a wealthy family in Bungay, England, near Norwich. Her maiden name was Susanna Strickland. In 1832, she married Lieutenant J. W. D. Moodie, an officer in the British army. In that year, Moodie immigrated with her husband to the area north of Lake Ontario in what was then called Upper Canada. From 1839 to 1851, Moodie wrote fiction and poetry for the *Literary Garland,* a Canadian magazine.

Rosemary Sullivan

Moody, Dwight Lyman (1837-1899), was an American evangelist. He founded the interdenominational Moody Memorial Church, the Moody Bible Institute, and the Moody Press in Chicago (see **Moody Bible Institute**). He also established a private high school for girls and another for boys near Northfield, Mass.

Moody was born in East Northfield, Mass. He left a job as a clerk in a Boston shoe store to become a shoe salesman in Chicago in 1856. He devoted all his time to Sunday school and YMCA activities after 1860. He conducted great evangelistic campaigns in the United States and Britain, appearing with Ira D. Sankey, a gospel singer and hymn writer. Henry Warner Bowden

Moody, Helen Wills. See Wills, Helen N.

Moody, Maryon Elspeth. See Pearson, Lester Bowles (Education and war service).

Moody, William Vaughn (1869-1910), was an American dramatist, poet, teacher, and literary historian. Critics hailed his play *The Great Divide* (1906) as a landmark in American drama because of its frank, naturalistic treatment of the collision between eastern puritanism and western frontier individualism. Moody planned a verse *trilogy* (three related plays) on the theme of "the unity of God and man." He completed *The Masque of Judgment* (1900) and *The Fire Bringer* (1904), but died before finishing the third play, *The Death of Eve.* He also wrote *The Faith Healer* (1909).

Moody's *Poems* (1901) contain the well-known lyrics "Gloucester Moors" and "The Quarry." While teaching at the University of Chicago, Moody wrote *History of English Literature* (1902) with Robert Morss Lovett. Moody was born in Spencer, Ind. Frederick C. Wilkins

Moody Bible Institute, in Chicago, is an independent school that trains pastors, missionaries, and church-related workers. It offers bachelor's degrees, graduate and adult-education classes, and conducts a worldwide correspondence school. The institute operates 11 radio stations, the Moody Broadcasting Network, and Moody Press Publishers, and publishes *Moody Monthly* magazine. The Moody Institute of Science, in Whittier, Calif., produces religious and science films.

Dwight Lyman Moody, an evangelist, founded the institute in 1886. He established it to educate men and women in spreading the message of the Bible to the poor and working classes.

Lunar and Planetary Institute

The moon's surface shows striking contrasts of light and dark. The light areas are rugged highlands. The dark zones were partly flooded by lava when volcanoes erupted billions of years ago. The lava froze to form smooth rock.

Moon

Moon is Earth's only natural satellite and the only astronomical body other than Earth ever visited by human beings. The moon is the brightest object in the night sky but gives off no light of its own. Instead, it reflects light from the sun. Like Earth and the remainder of the solar system, the moon is about 4.6 billion years old.

The moon is much smaller than Earth. The moon's average *radius* (distance from its center to its surface) is 1,079.4 miles (1,737.1 kilometers), about 27 percent of the radius of Earth.

The moon is also much less massive than Earth. The moon has a *mass* (amount of matter) of 8.10×10^{19} tons (7.35×10^{19} metric tons). The latter number would be written out as 735 followed by 17 zeroes. Earth is about 81 times that massive. The moon's *density* (mass divided by volume) is about 3.34 grams per cubic centimeter, roughly 60 percent of Earth's density.

Because the moon has less mass than Earth, the force due to gravity at the lunar surface is only about $\frac{1}{6}$ of that on Earth. Thus, a person standing on the moon would feel as if his or her weight had decreased by $\frac{5}{6}$. And if that person dropped a rock, the rock would fall to the surface much more slowly than the same rock would fall to Earth.

Paul D. Spudis, the contributor of this article, is Deputy Director of the Lunar and Planetary Institute in Houston.

Despite the moon's relatively weak gravitational force, the moon is close enough to Earth to produce tides in Earth's waters. The average distance from the center of Earth to the center of the moon is 238,897 miles (384,467 kilometers). That distance is growing—but extremely slowly. The moon is moving away from Earth at a speed of about 1 $\frac{1}{2}$ inches (3.8 centimeters) per year.

The temperature at the lunar equator ranges from extremely low to extremely high—that is, from about −280 °F (−173 °C) at night to 260 °F (127 °C) in the daytime. In some deep craters near the moon's poles, the temperature is always near −400 °F (−240 °C).

The moon has no life of any kind on it. Compared with Earth, it has changed little over billions of years. On the moon, the sky is black—even during the day—and the stars are always visible.

A person on Earth looking at the moon with the unaided eye can see light and dark areas on the lunar sur-

face. The light areas are rugged, cratered highlands known as *terrae* (pronounced *TEHR ee*). *Terrae* is Latin for *lands*. The highlands are the original crust of the moon, shattered and fragmented by the impact of meteoroids, asteroids, and comets. Many craters in the terrae exceed 25 miles (40 kilometers) in diameter. The largest is the South Pole-Aitken Basin, which is 1,550 miles (2,500 kilometers) in diameter.

The dark areas on the moon are known as *maria (MAHR ee uh)*. *Maria* is Latin for *seas;* its singular is *mare (MAHR ee)*. The term comes from the smoothness of the dark areas and their resemblance to bodies of water. The maria are areas that were partly flooded by lava when volcanoes erupted billions of years ago. The lava then froze, forming smooth rock. Since that time, meteoroid impacts have created craters in the maria.

The moon has no substantial atmosphere, but small amounts of certain gases are present above the lunar surface. People sometimes refer to those gases as the lunar atmosphere. It can also be called an *exosphere,* defined as a *tenuous* (low-density) zone of particles surrounding an airless body. Mercury and some asteroids also have an exosphere.

In 1959, scientists began to explore the moon with robot spacecraft. In that year, the Soviet Union sent a spacecraft called Luna 3 around the side of the moon that faces away from Earth. Luna 3 took the first photographs of that side of the moon. The word *luna* is Latin for *moon*.

On July 20, 1969, the United States Apollo 11 lunar module landed on the moon in the first of six Apollo landings. Astronaut Neil A. Armstrong became the first human being to set foot on the moon.

In the 1990's, two U.S. robot space probes, Clementine and Lunar Prospector, detected probable evidence of frozen water at both of the moon's poles. The ice may have come from comets that hit the moon over the last 2 billion to 3 billion years. The ice apparently has lasted in the shadows of crater rims. Because the ice is in the shade, where the temperature is about −400 °F (−240 °C), the ice has not melted and evaporated.

The movements of the moon

The moon moves in a variety of ways. For example, it rotates on its *axis,* an imaginary line that connects its poles. The moon also orbits Earth. Different amounts of the moon's lighted side become visible in *phases* because of the moon's orbit around Earth. During events called *eclipses,* the moon is positioned in line with Earth and the sun. A slight motion called *libration* enables us to see about 59 percent of the moon's surface at different times.

Rotation and orbit. The moon rotates on its axis once every 29 $\frac{1}{2}$ days. That is the period from one sunrise to the next, as seen from the lunar surface, and so it is known as a *lunar day*. By contrast, Earth takes only 24 hours for one rotation.

The moon's axis of rotation, like that of Earth, is tilted. Astronomers measure axial tilt relative to a line perpendicular to the *ecliptic plane,* an imaginary surface through Earth's orbit around the sun. The tilt of Earth's axis is about 23.5° from the perpendicular and accounts for the seasons on Earth. But the tilt of the moon's axis is only about 1.5°, so the moon has no seasons.

The moon at a glance

Age: About 4.6 billion years.
Distance from Earth:
Shortest: 225,740 miles (363,300 kilometers).
Greatest: 251,970 miles (405,500 kilometers).
Average: 238,897 miles (384,467 kilometers).
Radius, distance from the moon's center to its surface: 1,079.4 miles (1,737.1 kilometers), about 27 percent of Earth's radius.
Volume: 5.27 billion cubic miles (22.0 billion cubic kilometers), about $\frac{1}{50}$ the volume of Earth.
Mass, amount of matter: 8.10×10^{19} tons. This number would be written out as 81 followed by 18 zeroes. It is equivalent to 7.35×10^{19} metric tons and is about $\frac{1}{81}$ the mass of Earth.
Density: 3.34 grams per cubic centimeter, about $\frac{3}{5}$ the density of Earth.
Surface gravity: About $\frac{1}{6}$ that of Earth.
Temperature at equator: −280 to 260 °F (−173 to 127 °C).
Atmosphere: An *exosphere* consisting of small amounts of various gases is present above the surface.
Rotation period:
Relative to the stars: 27 days 7 hours 43 minutes.
Relative to the sun: 29 days 12 hours 43 minutes.
Revolution period around Earth:
Relative to the stars: 27 days 7 hours 43 minutes.
Relative to the sun: 29 days 12 hours 43 minutes.
Average speed around Earth: 2,289 miles (3,683 kilometers) per hour.

Another result of the smallness of the moon's tilt is that certain large peaks near the poles are always in sunlight. In addition, the floors of some craters—particularly near the south pole—are always in shadow.

The moon completes one orbit of Earth with respect to the stars about every 27 $\frac{1}{3}$ days, a period known as a *sidereal month*. But the moon revolves around Earth once with respect to the sun in about 29 $\frac{1}{2}$ days, a period known as a *synodic month*. A sidereal month is slightly shorter than a synodic month because, as the moon revolves around Earth, Earth is revolving around the sun. The moon needs some extra time to "catch up" with Earth. If the moon started on its orbit from a spot between Earth and the sun, it would return to almost the same place in about 29 $\frac{1}{2}$ days. See Month.

A synodic month equals a lunar day. As a result, the moon shows the same hemisphere—the *near side*—to Earth at all times. The other hemisphere—the *far side*—is always turned away from Earth.

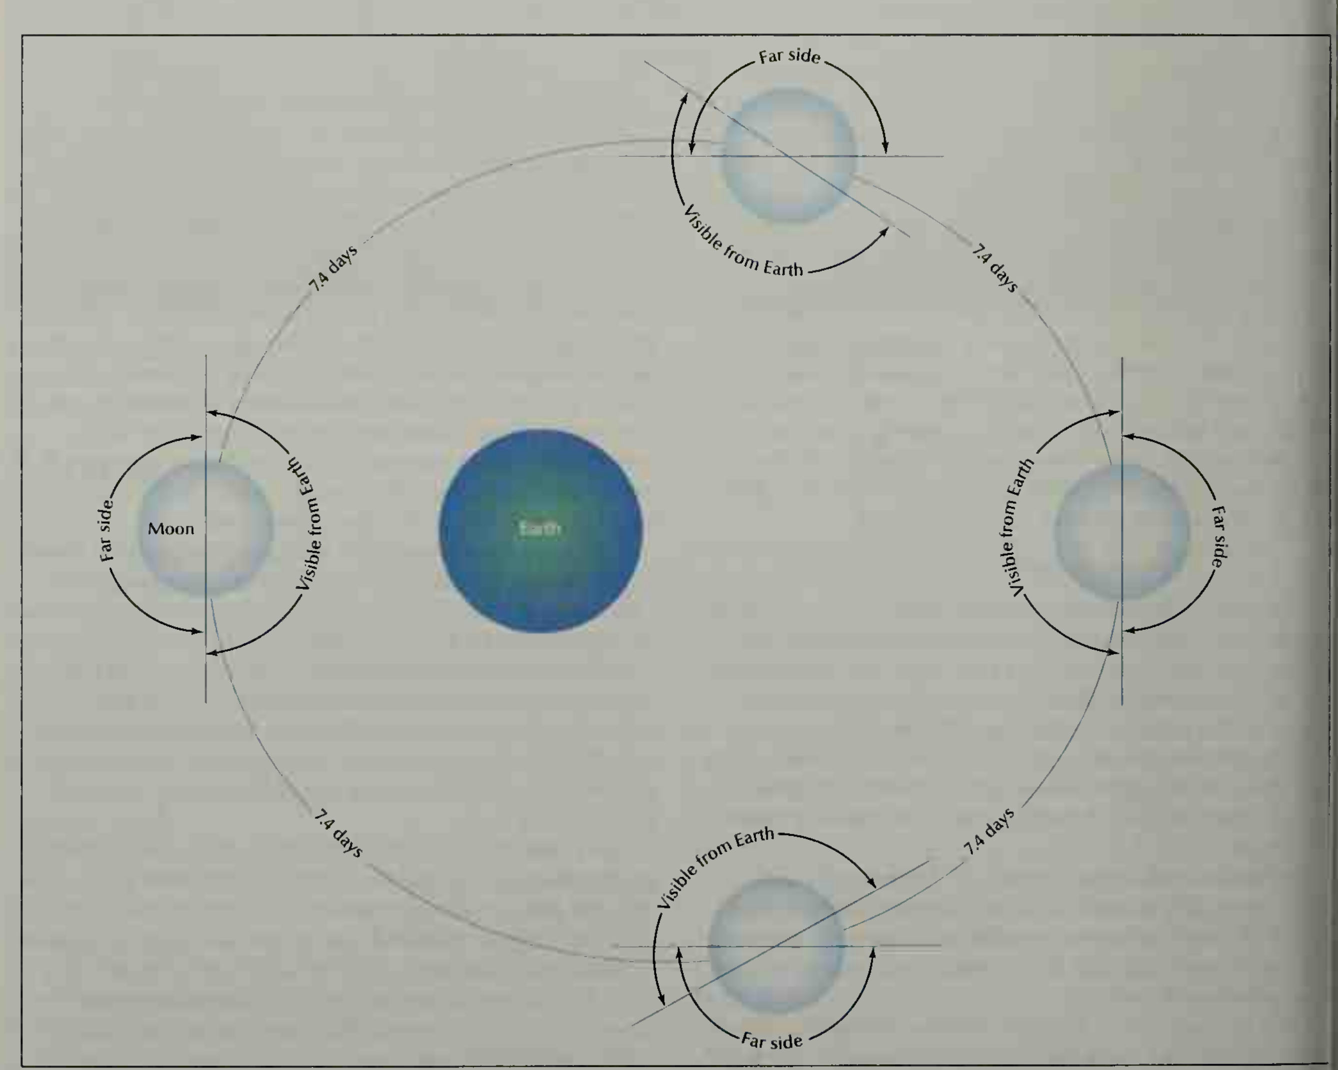
People sometimes mistakenly use the term *dark side* to refer to the far side. The moon does have a dark side—it is the hemisphere that is turned away from the sun. The location of the dark side changes constantly, moving with the *terminator,* the dividing line between sunlight and dark.

The lunar orbit, like the orbit of Earth, is shaped like a slightly flattened circle. The distance between the center of Earth and the moon's center varies throughout each orbit. At *perigee (PEHR uh jee),* when the moon is closest to Earth, that distance is 225,740 miles (363,300 kilometers). At *apogee (AP uh jee),* the farthest position, the distance is 251,970 miles (405,500 kilometers). The moon's orbit is *elliptical* (oval-shaped).

Phases. As the moon orbits Earth, an observer on Earth can see the moon appear to change shape. It seems to change from a crescent to a circle and back again. The shape looks different from one day to the next because the observer sees different parts of the

moon's sunlit surface as the moon orbits Earth. The different appearances are known as the *phases* of the moon. The moon goes through a complete cycle of phases in a synodic month.

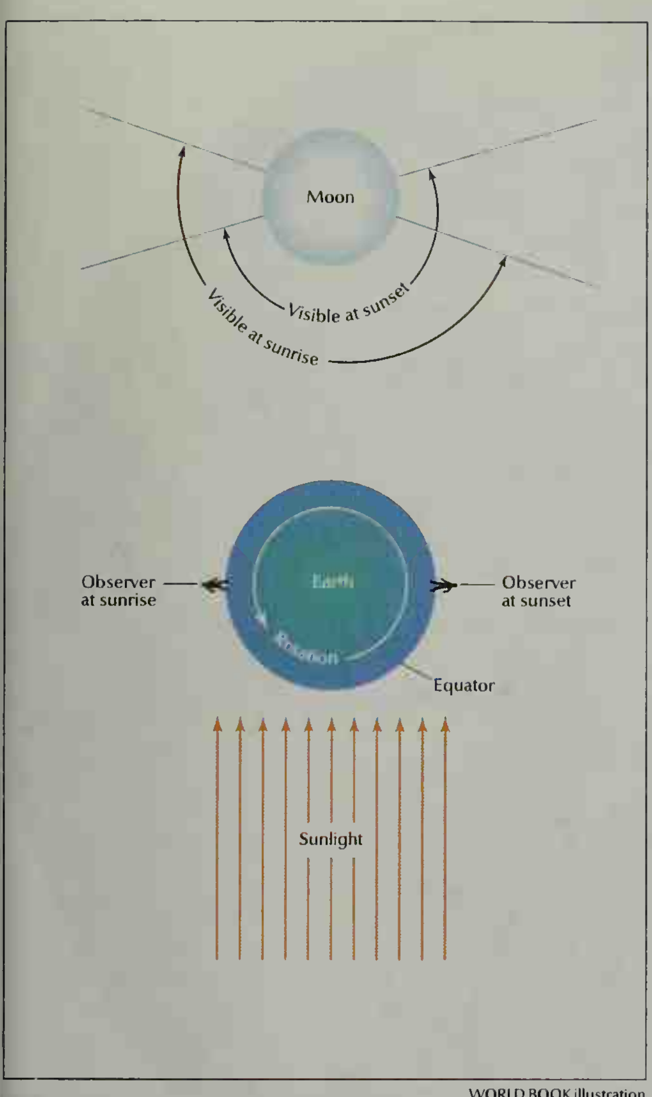
The moon has four phases: (1) new moon, (2) first quarter, (3) full moon, and (4) last quarter. When the moon is between the sun and Earth, its sunlit side is turned away from Earth. Astronomers call this darkened phase a *new moon.*



The next night after a new moon, a thin crescent of light appears along the moon's eastern edge. In clear skies, the remaining portion of the moon that faces Earth is faintly visible because of *earthshine,* sunlight reflected from Earth to the moon. Each night, an observer on Earth can see more of the sunlit side as the terminator, the line between sunlight and dark, moves westward. After about seven days, the observer can see half a full moon, commonly called a *half moon.* This phase is known as the *first quarter* because it occurs one-quarter of the way through the synodic month. About seven days later, the moon is on the side of Earth opposite the sun. The entire sunlit side of the moon is now visible. This phase is called *full moon.*

About seven days after full moon, the observer again sees a half moon. This phase is the *last quarter,* or *third quarter.* After another seven days, the moon is between Earth and the sun, and another new moon occurs.

As the moon changes from new moon to full moon, and more and more of it becomes visible, it is said to be *waxing.* As it changes from full moon to new moon, and less and less of it can be seen, it is *waning.* When the moon appears smaller than a half moon, it is called *crescent.* When it looks larger than a half moon, but is not yet a full moon, it is called *gibbous (GIHB uhs).*



Like the sun, the moon rises in the east and sets in the west. As the moon progresses through its phases, it rises and sets at different times. In the new moon phase, it rises with the sun and travels close to the sun across the sky. Each successive day, the moon rises an average of about 50 minutes later.

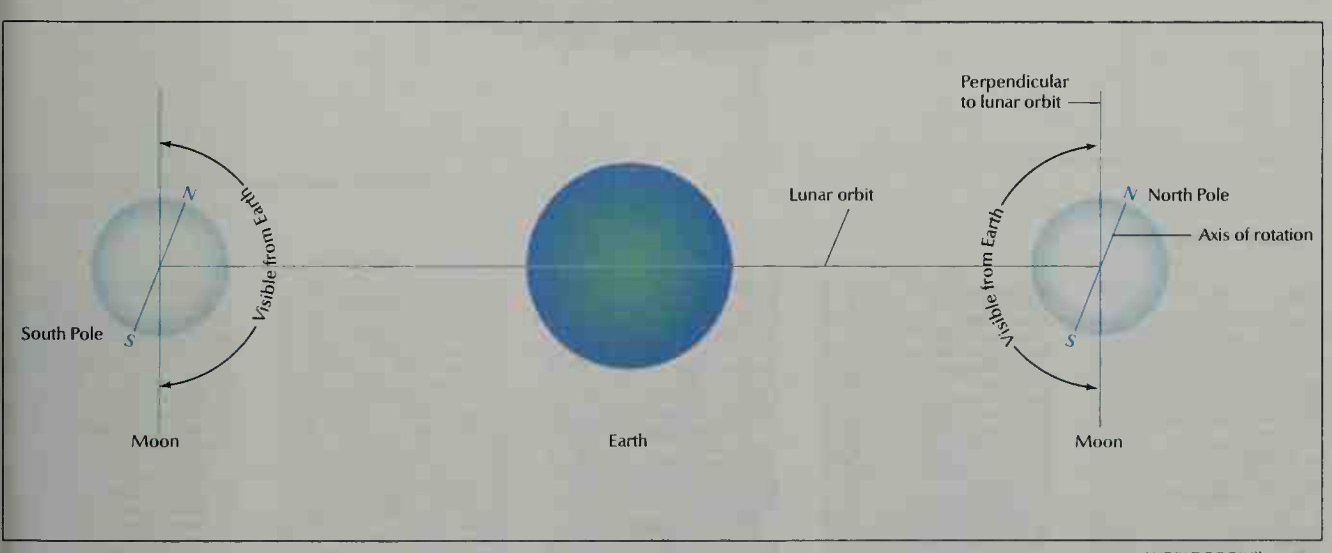
Eclipses occur when Earth, the sun, and the moon are in a straight line, or nearly so. A *lunar eclipse* occurs when Earth gets directly—or almost directly—between the sun and the moon, and Earth's shadow falls on the moon. A lunar eclipse can occur during only a full moon. A *solar eclipse* occurs when the moon gets di-

WORLD BOOK illustration

Libration in longitude enables observers on Earth to see one edge or the other of the far side of the moon. Libration in longitude occurs because the moon's rate of travel around Earth varies, but the moon always rotates on its own axis at the same speed. At certain times, the moon's orbital speed is so high that the far side does not face directly away from Earth. At other times, a low orbital speed prevents the far side from facing directly away. This diagram is not drawn to scale.

WORLD BOOK illustration

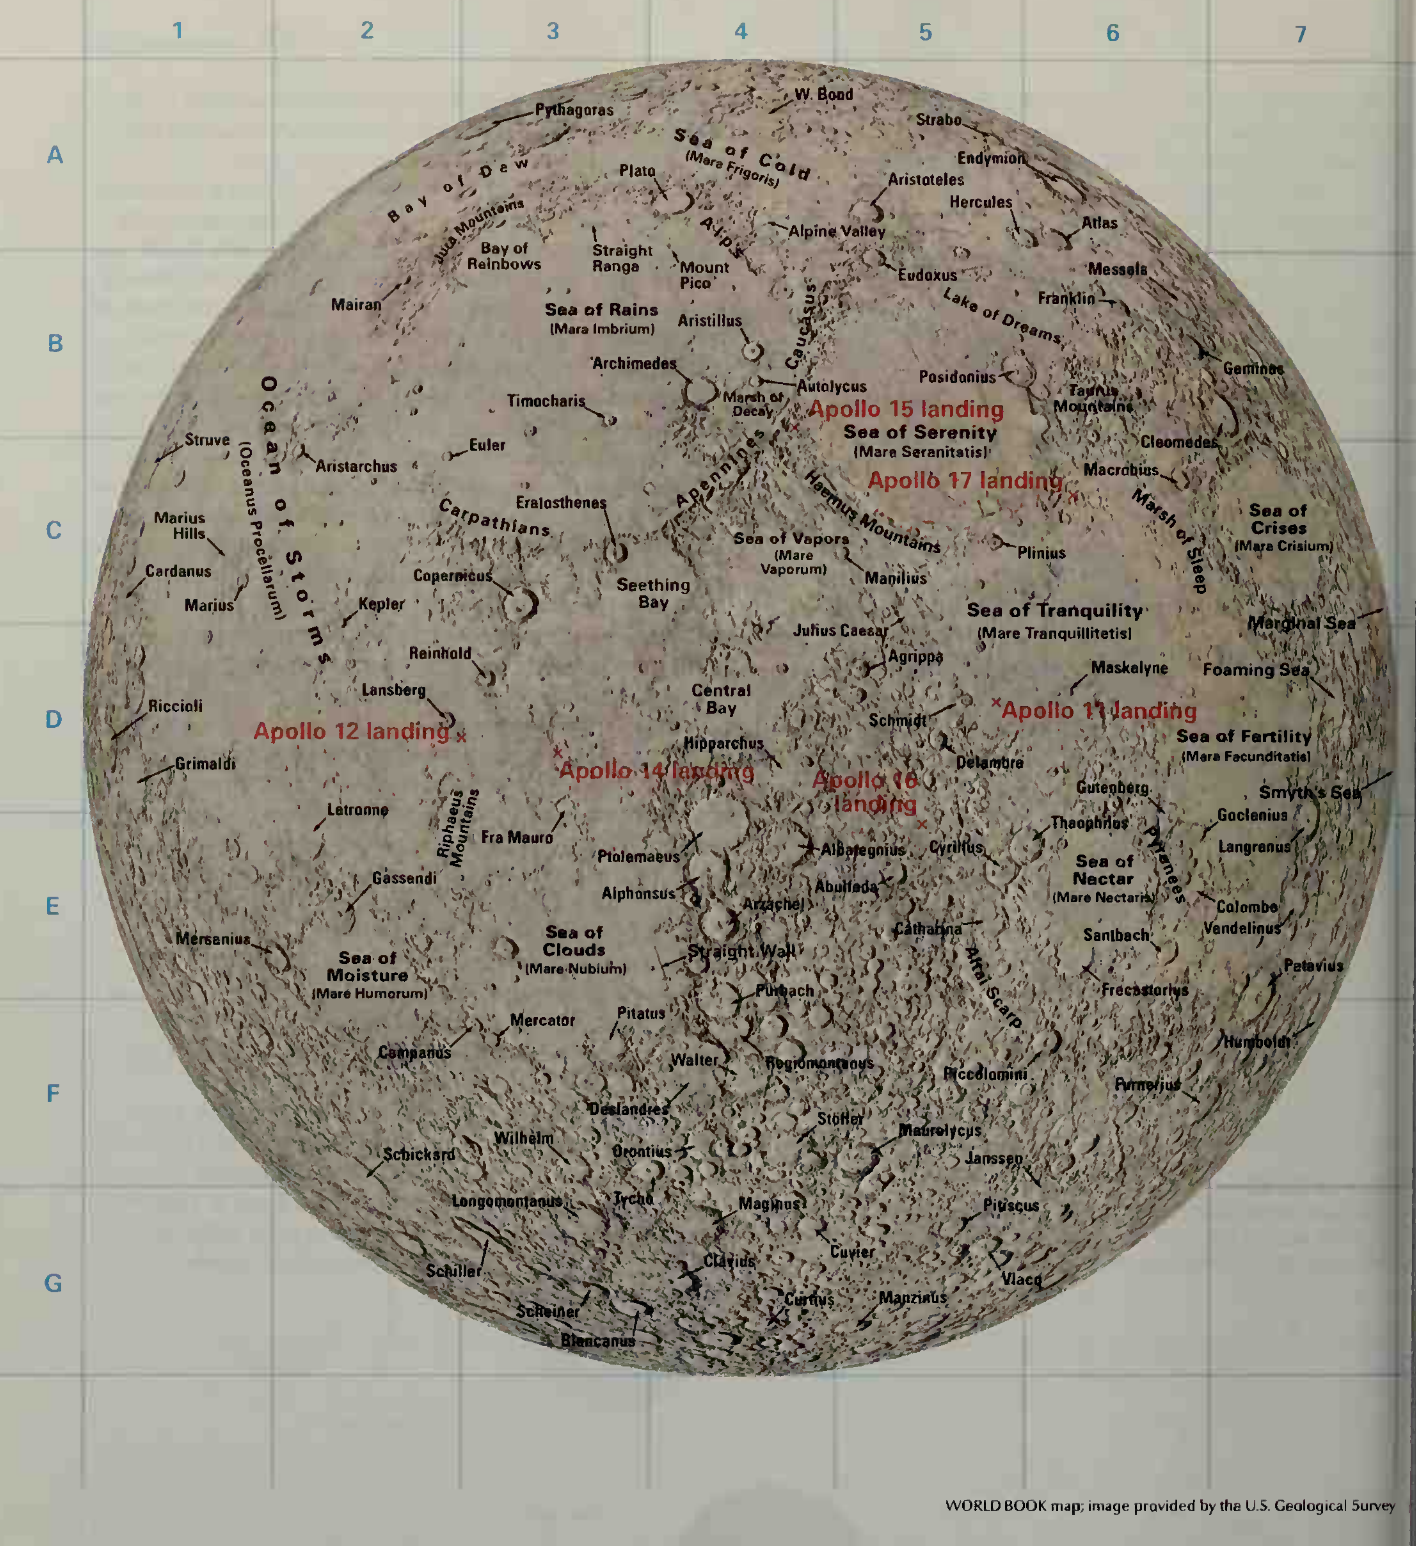
Diurnal libration enables an observer on Earth to see around one edge of the moon, then the other, during a single night. The libration occurs because Earth's rotation changes the observer's viewpoint by a distance equal to the diameter of the Earth.



rectly—or almost directly—between the sun and Earth, and the moon's shadow falls on Earth. A solar eclipse can occur during only a new moon.

During one part of each lunar orbit, Earth is between the sun and the moon; and, during another part of the orbit, the moon is between the sun and Earth. But in most cases, the astronomical bodies are not aligned directly enough to cause an eclipse. Instead, Earth casts its shadow into space above or below the moon, or the moon casts its shadow into space above or below Earth. The shadows extend into space in that way because the moon's orbit is tilted about 5° relative to Earth's orbit around the sun. See **Eclipse.**

Libration. People on Earth can sometimes see a small part of the far side. That area is visible because of lunar *libration,* a slight rotation of the moon as viewed from Earth. There are three kinds of libration: (1) libration in longitude, (2) *diurnal* (daily) libration, and (3) libration in latitude. Over time, viewers can see more than 50 percent of the moon's surface. Because of libration, about 59 percent of the lunar surface is visible from Earth.



Libration in longitude occurs because the moon's orbit is elliptical. As the moon orbits Earth, its speed varies according to a law discovered in the 1600's by the German astronomer Johannes Kepler. When the moon is relatively close to Earth, the moon travels more rapidly than its average speed. When the moon is relatively far from the Earth, the moon travels more slowly than average. But the moon always rotates about its own axis at the same rate. So when the moon is traveling more rapidly than average, its rotation is too slow to keep all of the near side facing Earth. And when the moon is traveling more slowly than average, its rotation is too rapid to keep all of the near side facing Earth.

Diurnal libration is caused by a daily change in the position of an observer on Earth relative to the moon. Consider an observer who is at Earth's equator when the moon is full. As Earth rotates from west to east, the observer first sees the moon when it rises at the eastern horizon and last sees it when it sets at the western hori-

WORLD BOOK illustration

Libration in latitude enables an observer on Earth to see beyond the moon's north pole during one part of the moon's revolution around Earth, and beyond the moon's south pole during another part of that revolution. Libration in latitude occurs because the moon's axis of rotation is not exactly perpendicular to its orbit. During each revolution, its north pole tilts first toward Earth, then away.

zon. During this time, the observer's viewpoint moves about 7,900 miles (12,700 kilometers)—the diameter of Earth—relative to the moon. As a result, the moon appears to rotate slightly to the west.

As the moon rises in the east and then climbs to its highest point in the sky, the observer can see around the western edge of the near side. As the moon descends to the western horizon, the observer can see around the eastern edge of the near side.

Libration in latitude occurs because the moon's axis of rotation is tilted about $6\frac{1}{2}°$ relative to a line perpendicular to the moon's orbit around Earth. Thus, during each lunar orbit, the moon's north pole tilts first toward Earth, then away from Earth. When the lunar north pole is tilted toward Earth, people on Earth can see farther than normal along the top of the moon. When that pole is tilted away from Earth, people on Earth can see farther than normal along the bottom of the moon.

Origin and evolution of the moon

Scientists believe that the moon formed as a result of a collision known as the Giant Impact or the "Big Whack." According to this idea, Earth collided with a planet-sized object 4.6 billion years ago. As a result of the impact, a cloud of vaporized rock shot off Earth's surface and went into orbit around Earth. The cloud cooled and condensed into a ring of small, solid bodies, which then gathered together, forming the moon.

The rapid joining together of the small bodies released much energy as heat. Consequently, the moon melted, creating an "ocean" of *magma* (melted rock).

The magma ocean slowly cooled and solidified. As it cooled, dense, iron-rich rocks sank deep into the moon. Those materials also cooled and solidified, forming the *mantle,* the layer of rock beneath the crust.

As the crust formed, asteroids bombarded it heavily, shattering and churning it. The largest impacts may have stripped off the entire crust. Some collisions were so powerful that they almost split the moon into pieces. One collision created the South Pole-Aitken Basin, one of the largest known impact craters in the solar system.

About 4 billion to 3 billion years ago, melting occurred in the mantle, probably caused by radioactive elements deep in the moon's interior. The resulting magma erupted as dark, iron-rich lava, partly flooding the heavily cratered surface. The lava cooled and solidified into rocks known as *basalts (buh SAWLTS).*

Small eruptions may have continued until as recently as 1 billion years ago. Since that time, only an occasional impact by an asteroid or comet has modified the surface. Because the moon has no atmosphere to burn up meteoroids, the bombardment continues to this day. However, it has become much less intense.

Impacts of large objects can create craters. Impacts of *micrometeoroids* (tiny meteoroids) grind the surface rocks into a fine, dusty powder known as the *regolith (REHG uh lihth).* Regolith overlies all the bedrock on the moon. Because regolith forms as a result of exposure to space, the longer a rock is exposed, the thicker the regolith that forms on it.

A tremendous collision between Earth and a smaller object led to the birth of the moon. Debris from the impact went into orbit in a ring around Earth, then gathered together to form the moon.

The exosphere of the moon

The lunar exosphere—that is, the materials surrounding the moon that make up that lunar "atmosphere"—consists mainly of gases that arrive as the *solar wind.* The solar wind is a continuous flow of gases from the sun—mostly hydrogen and helium, along with some neon and argon.

The remainder of the gases in the exosphere form on the moon. A continual "rain" of micrometeoroids heats lunar rocks, melting and vaporizing their surface. The most common atoms in the vapor are atoms of sodium and potassium. Those elements are present in tiny amounts—only a few hundred atoms of each per cubic centimeter of exosphere. In addition to vapors produced by impacts, the moon also releases some gases from its interior.

Most gases of the exosphere concentrate about halfway between the equator and the poles, and they are most plentiful just before sunrise. The solar wind continuously sweeps vapor into space, but the vapor is continuously replaced.

During the night, the pressure of gases at the lunar surface is about 3.9×10^{-14} pound per square inch (2.7×10^{-10} pascal). That is a stronger vacuum than laboratories on Earth can usually obtain. The exosphere is so tenuous—that is, so low in density—that the rocket exhaust released during each Apollo landing temporarily doubled its mass.

Surface features of the moon

The surface of the moon is covered with bowl-shaped holes called *craters,* shallow depressions called *basins,* and broad, flat plains known as *maria.* A powdery dust called the *regolith* overlies much of the surface of the moon.

Craters. The vast majority of the moon's craters are formed by the impact of meteoroids, asteroids, and comets. Craters on the moon are named for famous scientists. For example, Copernicus Crater is named for Nicolaus Copernicus, a Polish astronomer who realized in the 1500's that the planets move about the sun. Archimedes Crater is named for the Greek mathematician Archimedes, who made many mathematical discoveries in the 200's B.C.

The shape of craters varies with their size. Small craters with diameters of less than 6 miles (10 kilometers) have relatively simple bowl shapes. Slightly larger craters cannot maintain a bowl shape because the crater wall is too steep. Material falls inward from the wall to the floor. As a result, the walls become scalloped and the floor becomes flat.

Still larger craters have terraced walls and central peaks. Terraces inside the rim descend like stairsteps to the floor. The same process that creates wall scalloping is responsible for terraces. The central peaks almost certainly form as did the central peaks of impact craters on Earth. Studies of the peaks on Earth show that they result from a deformation of the ground. The impact compresses the ground, which then rebounds, creating the peaks. Central peaks of lunar craters may come from depths as great as 12 miles (19 kilometers).

Surrounding the craters is rough, mountainous material—crushed and broken rocks that were ripped out of the crater cavity by shock pressure. This material, called the *crater ejecta blanket,* can extend about 60 miles (100 kilometers) from the crater.

Farther out are patches of debris and, in many cases, irregular *secondary craters,* also known as *secondaries.* Those craters come in a range of shapes and sizes, and they are often clustered in groups or aligned in rows. Secondaries form when material thrown out of the *primary* (original) crater strikes the surface. This material consists of large blocks, clumps of loosely joined rocks, and fine sprays of ground-up rock. The material may travel thousands of miles or kilometers.

Crater rays are light, wispy deposits of powder that can extend thousands of miles or kilometers from some craters. Rays slowly vanish as micrometeoroid bombardment mixes the powder into the upper surface layer. Thus, craters that still have visible rays must be among the youngest craters on the moon.

Craters larger than about 120 miles (200 kilometers) across tend to have central mountains. Some of them also have inner rings of peaks, in addition to the central peak. The appearance of a ring signals the next major transition in crater shape—from crater to basin.

Basins are craters that are 190 miles (300 kilometers) or more across. The smaller basins have only a single inner ring of peaks, but the larger ones typically have multiple rings. The rings are *concentric*—that is, they all have the same center, like the rings of a dartboard. The spectacular, multiple-ringed basin called the Eastern Sea (Mare Orientale) is almost 600 miles (1,000 kilometers) across. Other basins can be more than 1,200 miles (2,000 kilometers) in diameter—as large as the entire western United States.

Basins occur equally on the near side and far side. Most basins have little or no fill of basalt, particularly those on the far side. The difference in filling may be related to variations in the thickness of the crust. The far side has a thicker crust, so it is more difficult for molten rock to reach the surface there.

In the highlands, the overlying ejecta blankets of the basins make up most of the upper few miles or kilometers of material. Much of this material is a large, thick layer of shattered and crushed rock known as *breccia (BREHCH ee uh).* Scientists can learn about the original crust by studying tiny fragments of breccia.

Maria, the dark areas on the surface of the moon, make up about 16 percent of the surface area. Some maria are named in Latin for weather terms—for example, Mare Imbrium (Sea of Rains) and Mare Nubium (Sea of Clouds). Others are named for states of mind, as in Mare Serenitatus (Sea of Serenity) and Mare Tranquillitatis (Sea of Tranquility).

Lunar and Planetary Institute

Euler Crater has central peaks and slumped walls. The peaks almost certainly formed quickly after the impact that produced the crater compressed the ground. The ground rebounded upward, forming the peaks. The crater walls are slumped because the original walls were too steep to withstand the force of gravity. Material fell inward, away from the walls. This crater, in Mare Imbrium (Sea of Rains), is about 17 $\frac{1}{2}$ miles (28 kilometers) across.

Lunar and Planetary Institute

A basalt rock that astronauts brought to Earth from the moon formed from lava that erupted from a lunar volcano. Escaping gases created the holes before the lava solidified into rock.

Landforms on the maria tend to be smaller than those of the highlands. The small size of mare features relates to the scale of the processes that formed them—volcanic eruptions and crustal deformation, rather than large impacts. The chief landforms on the maria include *wrinkle ridges* and *rilles* and other volcanic features.

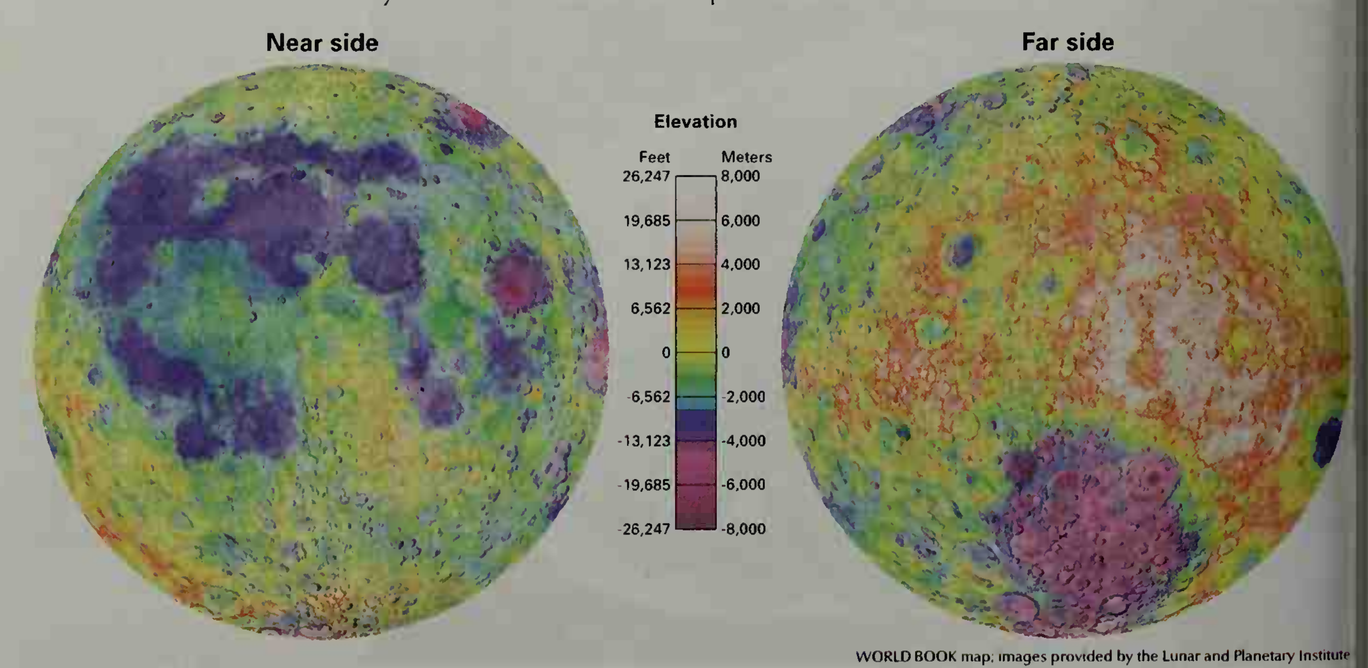
Wrinkle ridges are blisterlike humps that wind across the surface of almost all maria. The ridges are actually broad folds in the rocks, created by compression. Many wrinkle ridges are roughly circular, aligned with small peaks that stick up through the maria and outlining interior rings. Circular ridge systems also outline buried features, such as rims of craters that existed before the maria formed.

Rilles are snakelike depressions that wind across many areas of the maria. Scientists formerly thought the rilles might be ancient riverbeds. However, they now suspect that the rilles are channels formed by running lava. One piece of evidence favoring this view is the dryness of rock samples brought to Earth by Apollo astronauts; the samples have almost no water in their molecular structure. In addition, detailed photographs show that the rilles are shaped somewhat like channels created by flowing lava on Earth.

Volcanic features. Scattered throughout the maria are a variety of other features formed by volcanic eruptions. Within Mare Imbrium, *scarps* (lines of cliffs) wind their way across the surface. The scarps are *lava flow fronts,* places where lava solidified, enabling lava that was still molten to pile up behind them. The presence of the scarps is one piece of evidence indicating that the maria consist of solidified basaltic lava.

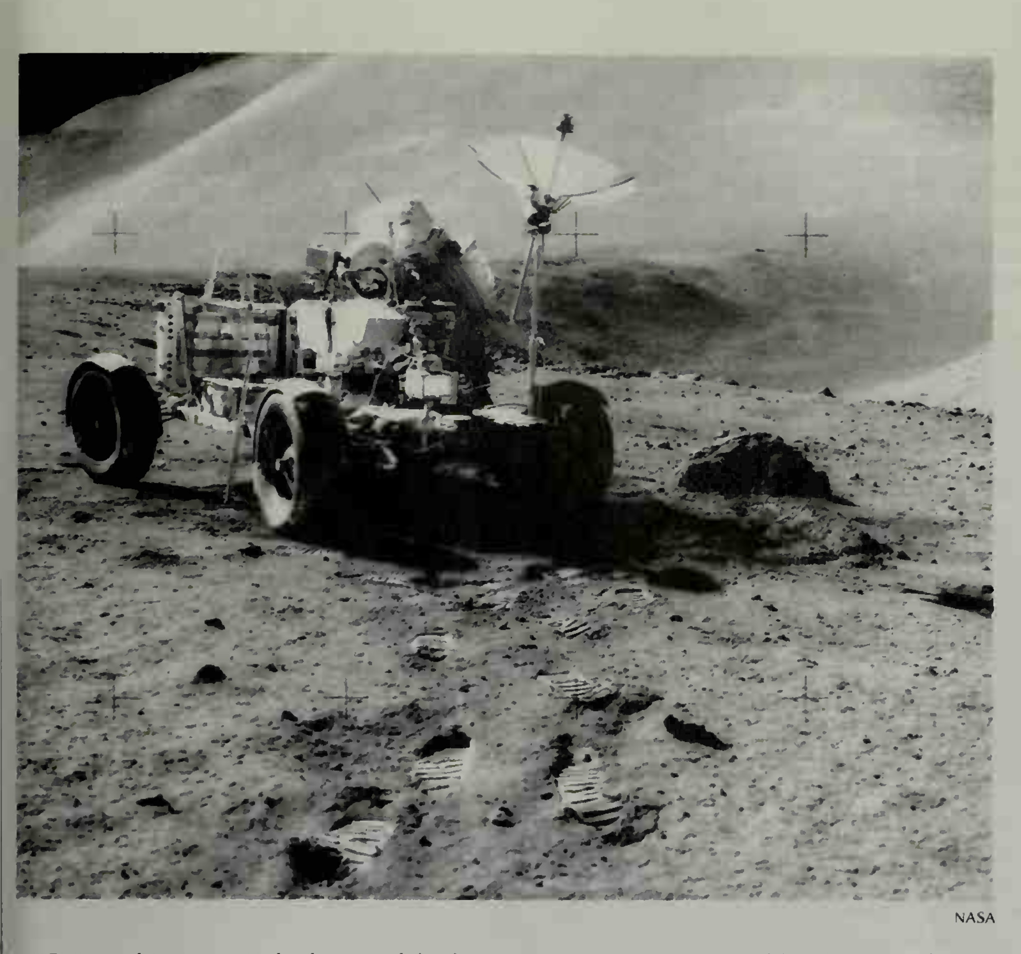
Small hills and domes with pits on top are probably little volcanoes. Both dome-shaped and cone-shaped volcanoes cluster together in many places, as on Earth. One of the largest concentrations of cones on the moon is the Marius Hills complex in Oceanus Procellarum (Ocean of Storms). Within this complex are numerous wrinkle ridges and rilles, and more than 50 volcanoes.

Large areas of maria and terrae are covered by dark material known as *dark mantle deposits.* Results from the Apollo missions confirmed that dark mantling is volcanic ash.



Much smaller dark mantles are associated with small craters that lie on the fractured floors of large craters. Those mantles may be *cinder cones*—low, broad, cone-shaped hills formed by explosive volcanic eruptions.

The interior of the moon



The moon, like Earth, has three interior zones—crust, mantle, and core. However, the composition, structure, and origin of the zones on the moon are much different from those on Earth.

Most of what scientists know about the interior of the Earth and the moon is learned by studying *seismic events*—earthquakes and moonquakes, respectively. The data on moonquakes came from scientific equipment set up by Apollo astronauts from 1969 to 1972.

The surface of the moon The elevations shown on these maps were measured by a laser device on the Clementine spacecraft that orbited the moon. The device determined the elevations by measuring the time taken by laser beams to travel from the spacecraft to the lunar surface and back.

WORLD BOOK map; images provided by the Lunar and Planetary Institute

NASA

A lunar rover is parked near the edge of Hadley Rille, a long channel probably formed by lava 4 billion to 3 billion years ago. The slopes in the background are part of a formation called the Swann Hills. This photo was taken during the Apollo 15 mission in 1971. Astronaut David R. Scott is reaching under a seat to get a camera.

Crust. The average thickness of the lunar crust is about 43 miles (70 kilometers), compared with about 6 miles (10 kilometers) for Earth's crust. The outermost part of the moon's crust is broken, fractured, and jumbled as a result of the large impacts it has endured. This shattered zone gives way to intact material below a depth of about 6 miles. The bottom of the crust is defined by an abrupt increase in rock density at a depth of about 37 miles (60 kilometers) on the near side and about 50 miles (80 kilometers) on the far side.

Mantle. The mantle of the moon consists of dense rocks that are rich in iron and magnesium. The mantle formed during the period of global melting. Low-density minerals floated to the outer layers of the moon, while dense minerals sank deeper into it.

Later, the mantle partly melted due to a build-up of heat in the deep interior. The source of the heat was probably the *decay* (breakup) of uranium and other radioactive elements. This melting produced *basaltic magmas*—bodies of molten rock. The magmas later made their way to the surface and erupted as the mare lavas and ashes. Although mare volcanism occurred for more than 1 billion years—from at least 4 billion years to fewer than 3 billion years ago—much less than 1 percent of the volume of the mantle ever remelted.

Core. Data gathered by Lunar Prospector confirmed that the moon has a core and enabled scientists to estimate its size. The core has a radius of only about 250 miles (400 kilometers). By contrast, the radius of Earth's core is about 2,200 miles (3,500 kilometers).

The lunar core has less than 1 percent of the mass of the moon. Scientists suspect that the core consists mostly of iron, and it may also contain large amounts of sulfur and other elements.

Earth's core is made mostly of molten iron and nickel. This rapidly rotating molten core is responsible for Earth's *magnetic field.* A magnetic field is an influence that a magnetic object creates in the region around it. If the core of a planet or a satellite is molten, motion within the core caused by the rotation of the planet or satellite makes the core magnetic. But the small, partly molten core of the moon cannot generate a global magnetic field. However, small regions on the lunar surface are magnetic. Scientists are not sure how these regions acquired magnetism. Perhaps the moon once had a larger, more molten core.

There is evidence that the lunar interior formerly contained gas, and that some gas may still be there. Basalt from the moon contains holes called *vesicles* that are created during a volcanic eruption. On Earth, gas that is dissolved in magma comes out of solution during an eruption, much as carbon dioxide comes out of a carbonated beverage when you shake the drink container. The presence of vesicles in lunar basalt indicates that the deep interior contained gases, probably carbon monoxide or gaseous sulfur. The existence of volcanic ash is further evidence of interior gas; on Earth, such eruptions are largely driven by gas.

History of moon study

Ancient ideas. Some ancient peoples believed that the moon was a rotating bowl of fire. Others thought it was a mirror that reflected Earth's lands and seas. But philosophers in ancient Greece understood that the moon is a sphere in orbit around Earth. They also knew that moonlight is reflected sunlight.

Some Greek philosophers believed that the moon was a world much like Earth. In about A.D. 100, Plutarch

even suggested that people lived on the moon. The Greeks also apparently believed that the dark areas of the moon were seas, while the bright regions were land.

In about A.D. 150, Ptolemy, a Greek astronomer who lived in Alexandria, Egypt, said that the moon was Earth's nearest neighbor in space. He thought that both the moon and the sun orbited Earth. Ptolemy's views survived for more than 1,300 years. But by the early 1500's, the Polish astronomer Nicolaus Copernicus had developed the correct view—Earth and the other planets revolve about the sun, and the moon orbits Earth.

Early observations with telescopes. The Italian astronomer and physicist Galileo wrote the first scientific description of the moon based on observations with a telescope. In 1609, Galileo described a rough, mountainous surface. This description was quite different from what was commonly believed—that the moon was smooth. Galileo noted that the light regions were rough and hilly and the dark regions were smoother plains.

The presence of high mountains on the moon fascinated Galileo. His detailed description of a large crater in the central highlands—probably Albategnius—began 350 years of controversy and debate about the origin of the "holes" on the moon.

Other astronomers of the 1600's mapped and cataloged every surface feature they could see. Increasingly powerful telescopes led to more detailed records. In 1645, the Dutch engineer and astronomer Michael Florent van Langren, also known as Langrenus, published a map that gave names to the surface features of the moon, mostly its craters. A map drawn by the Bohemian-born Italian astronomer Anton M. S. de Rheita in 1645 correctly depicted the bright ray systems of the craters Tycho and Copernicus. Another effort by the Polish astronomer Johannes Hevelius in 1647 included the moon's libration zones.

By 1651, two Jesuit scholars from Italy, the astronomer Giovanni Battista Riccioli and the mathematician and physicist Francesco M. Grimaldi, had completed a map of the moon. That map established the naming system for lunar features that is still in use.

Determining the origin of craters. Until the late 1800's, most astronomers thought that volcanism formed

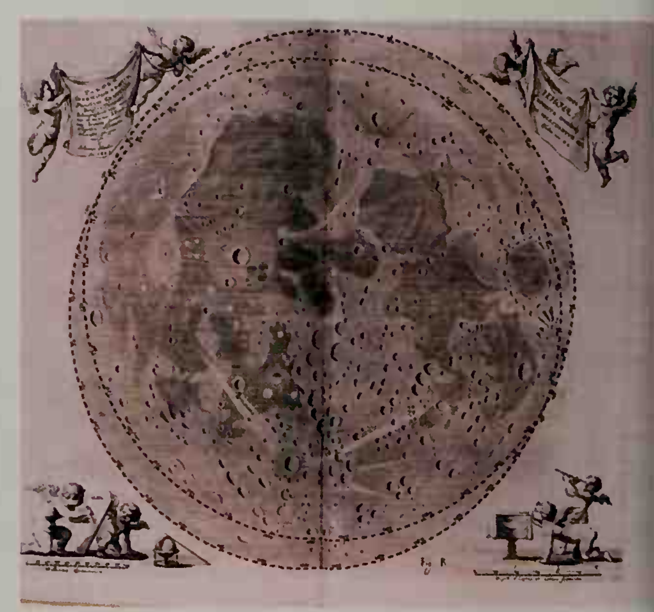


Illustration by Johannes Hevelius from Selenographia, Gdańsk, 1647; University of Chicago Library

An early moon map was drawn in 1647 by Johannes Hevelius, a city official of Gdańsk, Poland. Hevelius, an amateur astronomer, charted about 250 lunar formations with a telescope.

Milestones in moon study

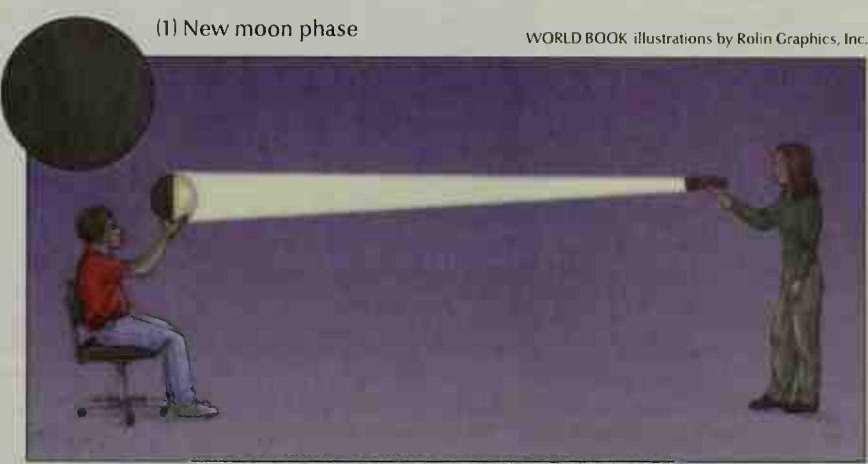
500's B.C. The Babylonians predicted the dates of eclipses.
c. 450 B.C. Anaxagoras, a Greek philosopher, noted that the moon's light comes from the sun.
c. 150 B.C. Hipparchus, a Greek astronomer, measured the period of the moon's revolution around Earth.
c. A.D. 150 Ptolemy, an astronomer in Egypt, said that the moon is Earth's nearest neighbor in space. But he also claimed that the moon and the sun orbit a motionless Earth.
1543 Nicolaus Copernicus, a Polish astronomer, revived the idea that Earth is a moving planet. Present-day astronomy is based on Copernicus's work.
c. 1600-1609 Johannes Kepler, a German astronomer, discovered basic laws of planetary and lunar motion.
1609-1610 Galileo, an Italian scientist, made the first practical use of the telescope to study the moon. He described a rough, mountainous lunar surface.
1645 Langrenus, a Dutch engineer and astronomer, completed a map that gave names to lunar craters and other features.
1647 Johannes Hevelius, a Polish astronomer, completed a map that included visible parts of the far side of the moon.
1687 A work written by Isaac Newton, an English scientist, explained the basis for the moon's motion and the moon's tidal effect on Earth.
1892 Grove Karl Gilbert, an American geologist, said that the moon is a complex body that was built up by countless impacts over a long period.
1949 Ralph B. Baldwin, an American astronomer and physicist, provided statistical evidence that lunar craters form by impact.
1959 The Soviet Union launched Luna 2, the first spaceship to hit the moon. The Soviet Union's Luna 3 sent the first pictures of the moon's far side back to Earth.
c. 1960 Eugene M. Shoemaker, an American geologist, showed that the relative ages of neighboring rock units on the moon can be determined and that the geological history of the lunar surface can therefore be studied.
1964-1965 U.S. Ranger spacecraft took the first close-up television pictures of the moon.
1966 The Soviet Union's Luna 9 became the first spacecraft to make a soft landing on the moon.
1966-1967 U.S. Lunar Orbiter craft mapped the moon's surface.
1966-1968 U.S. Surveyor spacecraft landed on the moon and sent close-up TV images of the lunar surface to Earth.
1968-1970 Soviet Zond spacecraft flew around the moon and returned to Earth.
1969 The Apollo 11 and Apollo 12 astronauts landed on the moon. They collected samples, took photographs, set up experiments, and explored areas near their landing sites.
1970 The Soviet Luna 16 craft landed on the moon and returned a sample of lunar soil to Earth.
1994 The U.S. orbiter Clementine took more than 2 million photos of the moon and measured its mountains and valleys. Radar signals bounced off the moon provided evidence of frozen water inside craters at the south pole.
1998-1999 Lunar Prospector, a U.S. orbiter, mapped concentrations of chemical elements on the moon, surveyed the moon's magnetic fields, and found strong evidence of ice at both poles.

A *World Book* science activity

Simulating the phases of the moon

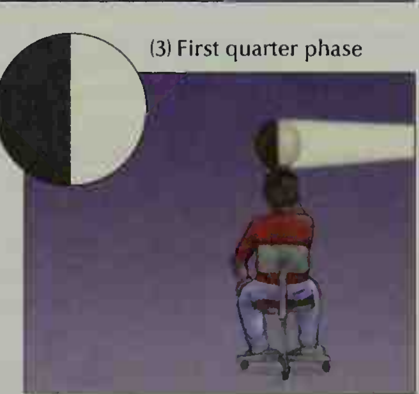
As the moon revolves around Earth, the appearance of the moon changes as viewed from Earth. Four of the appearances are known as *phases.* This activity will help you understand how the relationships between the sun, Earth, and moon in space create the phases of the moon. For this activity, you will need a swivel chair, a flashlight, a basketball—and an assistant. The light from the flashlight will represent sunlight, the ball will represent the moon, and you will represent an observer on Earth. Movements of the ball will simulate the revolution of the moon around Earth.

What to do:

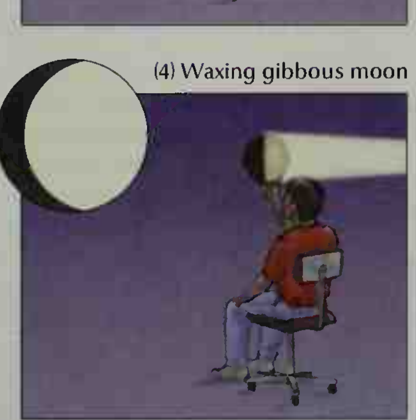


(1) Darken the room, then sit in the chair and hold the basketball as shown. Have your assistant stand about 10 feet (3 meters) away from you and shine the light on the ball. Your assistant should hold the flashlight so that you cannot see the light. In the position shown, you will see the dark side of the ball, which will represent a phase of the moon known as a *new moon.*

(2) Swivel one-eighth of a full turn counterclockwise without changing the position of your arm relative to the rest of your body. During this step and the remaining steps of this activity, your assistant should move the flashlight so that the full intensity of the light always shines on the ball and your head does not cast a shadow on the ball. In the position shown, you will see a sliver of light on the right-hand side of the ball. This appearance will represent a *waxing* (growing) *crescent* moon.



(3) Swivel another one-eighth of a turn counterclockwise. You will see light on the right-hand half of the ball, and the left-hand side of the ball will be dark. The corresponding phase is known as the *first quarter, half a full moon,* or a *half moon.*



(4) Swivel one-eighth of a turn five more times. At three-eighths of a full turn, you will see light corresponding to a *waxing gibbous* moon. At the succeeding turns, you will see light like that of (5) the *full moon* phase, (6) a *waning* (shrinking) *gibbous moon,* (7) the *third quarter* phase, and (8) a *waning crescent moon.*

the craters of the moon. However, in the 1870's, the English astronomer Richard A. Proctor proposed correctly that the craters result from the collision of solid objects with the moon. But at first few scientists accepted Proctor's proposal. Most astronomers thought that the moon's craters must be volcanic in origin because no one had yet recognized an impact crater on Earth as such, but scientists had found dozens of obviously volcanic craters.

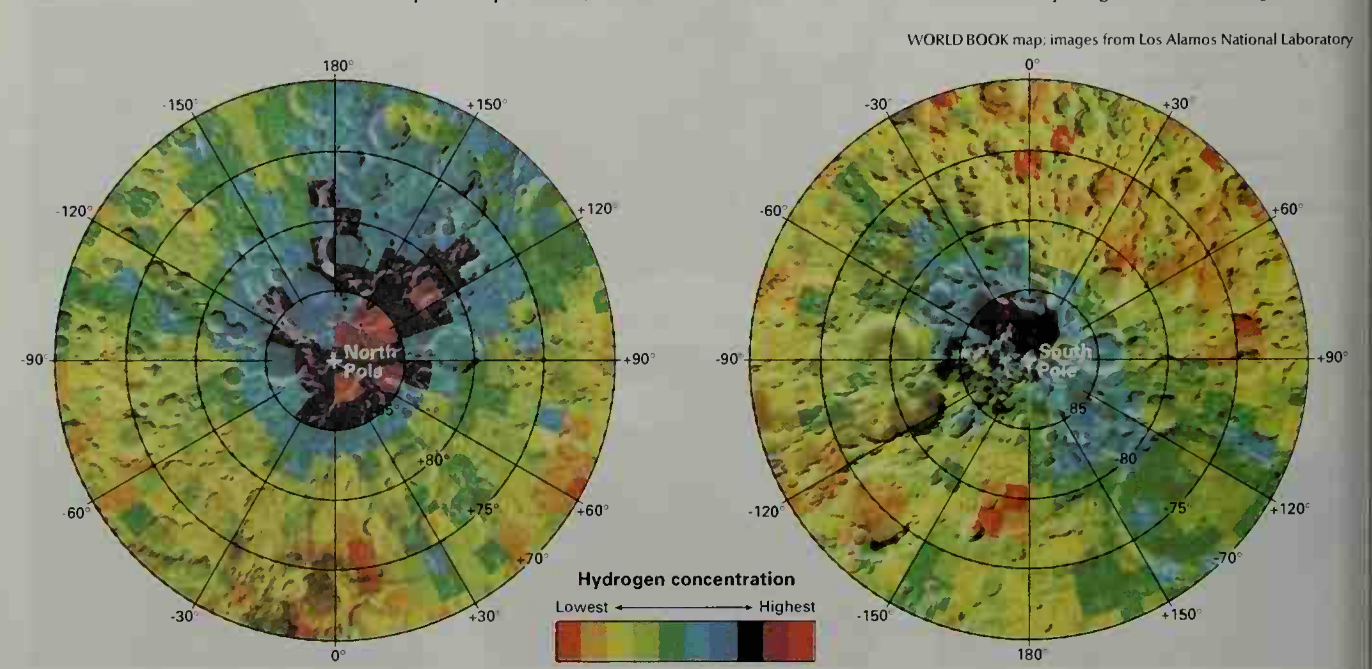
In 1892, the American geologist Grove Karl Gilbert argued that most lunar craters were impact craters. He based his arguments on the large size of some of the craters. Those included the basins. He was the first to recognize the basins as huge craters. Gilbert also noted that lunar craters have only the most general resemblance to *calderas* (large volcanic craters) on Earth. Both lunar craters and calderas are large circular pits, but their structural details do not resemble each other in any way.

In addition, Gilbert created small craters experimentally. He dropped clay balls and shot bullets into clay and sand targets.

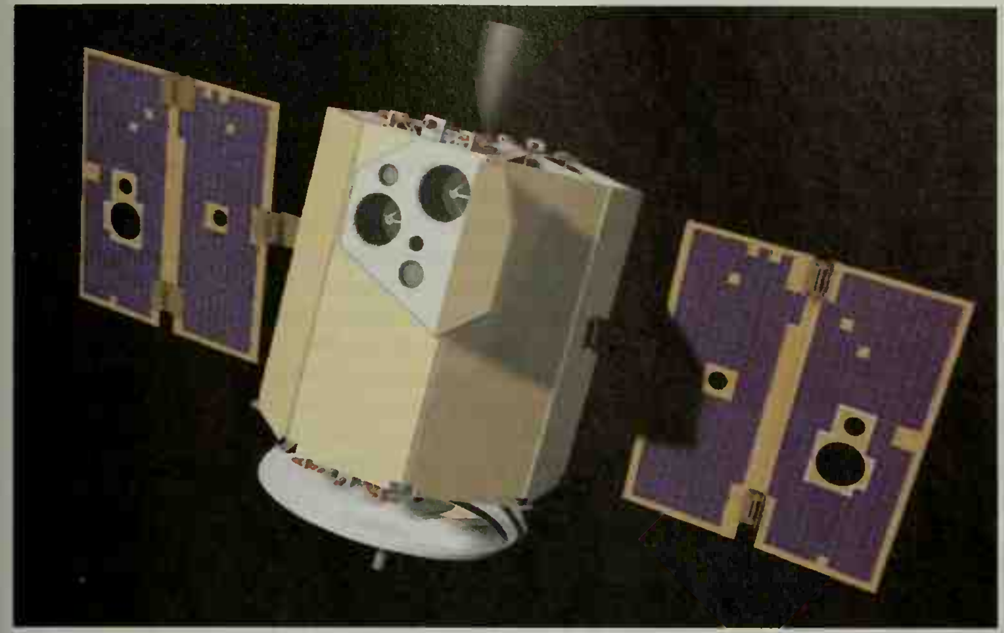
Gilbert was the first to recognize that the circular Mare Imbrium was the site of a gigantic impact. By examining photographs, Gilbert also determined which nearby craters formed before and after that event. For example, a crater that is partially covered by ejecta from the Imbrium impact formed before the impact. A crater within the mare formed after the impact.

Describing lunar evolution. Gilbert suggested that scientists could determine the relative age of surface features by studying the ejecta of the Imbrium impact. That suggestion was the key to unraveling the history of the moon. Gilbert recognized that the moon is a complex body that was built up by innumerable impacts over a long period.

In his book *The Face of the Moon* (1949), the American astronomer and physicist Ralph B. Baldwin further described lunar evolution. He noted the similarity in form between craters on the moon and bomb craters created during World War II (1939-1945) and concluded that lunar craters form by impact.



Baldwin did not say that every lunar feature originated with an impact. He stated correctly that the maria are solidified flows of basalt lava, similar to flood lava plateaus on Earth. Finally, independently of Gilbert, he concluded that all circular maria are actually huge impact craters that later filled with lava.



In the 1950's, the American chemist Harold C. Urey offered a contrasting view of lunar history. Urey said that, because the moon appears to be cold and rigid, it has always been so. He then stated—correctly—that craters are of impact origin. However, he concluded falsely that the maria are blankets of debris scattered by the impacts that created the basins. And he was mistaken in concluding that the moon never melted to any significant extent. Urey had won the 1934 Nobel Prize in chemistry and had an outstanding scientific reputation, so many people took his views seriously. Urey strongly favored making the moon a focus of scientific study. Although some of his ideas were mistaken, his support of moon study was a major factor in making the moon an early goal of the U.S. space program.

In 1961, the U.S. geologist Eugene M. Shoemaker founded the Branch of Astrogeology of the U.S. Geological Survey (USGS). Astrogeology is the study of celestial objects other than Earth. Shoemaker showed that the moon's surface could be studied from a geological perspective by recognizing a sequence of relative ages of rock units near the crater Copernicus on the near side. Shoemaker also studied Meteor Crater, Arizona, and documented the impact origin for this feature. In preparation for the Apollo missions to the moon, the USGS began to map the geology of the moon using telescopes and pictures. This work gave scientists their basic understanding of lunar evolution.

Evidence of ice on the moon

Large concentrations of hydrogen at the moon's polar regions were detected by the Lunar Prospector spacecraft, an almost certain indication of frozen water—hydrogen is the H in H_2O.

The Clementine orbiter used radar signals to find evidence of a large deposit of frozen water on the moon. The orbiter sent radar signals to various target points on the lunar surface. The targets reflected some of the signals to Earth, where they were received by large antennas and analyzed.

Lunar and Planetary Institute

Apollo missions. Beginning in 1959, the Soviet Union and the United States each sent a series of robot spacecraft to examine the moon in detail. Their ultimate goal was to land people safely on the moon. The United States finally reached that goal in 1969 with the landing of the Apollo 11 lunar module. The United States conducted six more Apollo missions, including five landings. The last of those was Apollo 17, in December 1972.

The Apollo missions revolutionized the understanding of the moon. Much of the knowledge gained about the moon also applies to Earth and the other inner planets—Mercury, Venus, and Mars. Scientists learned, for example, that impact is a fundamental geological process operating on the planets and their satellites.

After the Apollo missions, the Soviets sent four Luna robot craft to the moon. The last, Luna 24, returned small samples of lunar soil to Earth in August 1976.

Recent exploration. No more spacecraft went to the moon until January 1994, when the United States sent the orbiter Clementine there. From February to May of that year, Clementine's four cameras took more than 2 million pictures of the moon. A laser device measured the height and depth of mountains, craters, and other features. Radar signals that Clementine bounced off the moon provided evidence of a large deposit of frozen water. The ice appeared to be inside craters at the south pole.

The U.S. probe Lunar Prospector orbited the moon from January 1998 to July 1999. The craft mapped the concentrations of chemical elements in the moon, surveyed the moon's magnetic fields, and found strong evidence of ice at both poles. Small particles of ice are apparently part of the regolith at the poles. Paul D. Spudis

Questions

What causes the phases of the moon?
Why does the same side of the moon always face Earth?
What makes the moon "shine"?
In what year did the first astronaut set foot on the moon?
How do scientists believe the moon formed?
What are *maria?* How did they probably form?
What is the powdery material that overlies all the bedrock on the moon?
What is *libration?*
Where on the moon might there be deposits of frozen water?
Who wrote the first scientific description of the moon that was based on telescopic observation?

Moonflower is an attractive flower in the morning-glory family. It is a climbing vine that may grow 10 feet (3 meters) high. Its broad, heart-shaped leaves block sunlight and make an excellent screen for porches. The moonflower's pure white trumpet-shaped flowers may

WORLD BOOK illustration by Christabel King

The moonflower is an attractive climbing vine. The plant has broad, heart-shaped leaves and white trumpet-shaped flowers. Its large leaves make it a good sunscreen for porches.

be 3 to 6 inches (8 to 15 centimeters) across. These strongly scented flowers open at night and close in sunlight. The moonflower grows quickly. The parts of the plant aboveground die every year, but the roots remain alive. New parts grow from the roots each year.

Scientific classification. The moonflower is a member of the morning-glory family, Convolvulaceae. Its scientific name is *Ipomoea alba.* Daniel F. Austin

Moonies. See Cult.

Moonstone is a whitish variety of the mineral called *feldspar* (see **Feldspar**). Moonstone can be cut and used as a gem. It is a birthstone for June. Light will shine through it, but not so clearly as through glass. The stone also reflects light with a bluish to pearly-colored sheen that comes from inside the stone. Sri Lanka produces many moonstones. John C. Butler

See also **Birthstone; Gem** (picture).

Moor is a large area of open wasteland. A layer of peat that is usually wet covers some moors. The word is most often applied to the moors of Scotland and other parts of the British Isles, where heather grows in abundance. But there are also moors in northwest Europe and North America. Sphagnum moss grows on most moors, especially in North America. Many moors have special names. See also **Peat.** John W. Webb

Moore, Clement Clarke (1779-1863), an American scholar, is generally considered the author of the popular Christmas ballad "An Account of a Visit from St. Nicholas." The ballad is also known as "A Visit from St. Nicholas" and by its first line, "'Twas the Night Before Christmas." According to tradition, Moore wrote the poem in 1822 as a Christmas present for his children. The poem was first published anonymously in the *Troy* (N.Y.) *Sentinel* on Dec. 23, 1823. Some people have claimed that Henry Livingston, Jr., actually wrote the poem. Livingston was a New York land surveyor who also composed poetry.

Moore was born in New York City. He was a Biblical scholar and taught Greek and Oriental literature in the Episcopal seminaries of New York City from 1821 to 1850. Robert J. Myers

See also **Santa Claus** (Santa's appearance).

Moore, Douglas Stuart (1893-1969), was an American composer, best known for his operas on American subjects. He won the 1951 Pulitzer Prize for music for *Giants in the Earth,* based on Ole Rölvaag's novel about the hardships of Norwegian farmers in the Dakota Territory in the 1800's. Moore's most successful work, *The Ballad of Baby Doe* (1956), concerns a Colorado mining tycoon. *The Devil and Daniel Webster* (1939) is based on Stephen Vincent Benét's short story set in New England. Moore's other compositions include the symphonic suite *Pageant of P. T. Barnum* (1924) and the symphonic poem *Moby Dick* (1928).

Moore was born in Cutchogue, N.Y. He became a professor of music at Columbia University in 1926 and was head of its music department from 1940 to 1962. He wrote two books on music appreciation, *Listening to Music* (1932, enlarged 1937) and *From Madrigal to Modern Music* (1942). Richard Jackson

Moore, G. E. (1873-1958), a British philosopher, thought of philosophy as a rational approach to practical questions about the real world. In *ethics,* the branch of philosophy that deals with the nature of right and wrong, he was interested in how we know what is good. In his most widely read book, *Principia Ethica* (1903), Moore argued that we know good actions from bad ones by intuition, not by analyzing behavior according to logical concepts. Intuition must be used because it is not possible to define the idea of good.

Moore favored common sense as the best approach to argue against *idealism.* Idealism is the belief that the existence of things depends on the mind and ideas (see **Idealism**). He thought that common sense leads us to assume that material objects do exist independently of the mind.

Moore's impact on British philosophy was as much a result of his style as of his ideas. His habit of asking sharp and disturbing questions was compared to Socrates' method of posing questions. Moore's clear writing was compared to that of Plato. His other books include *Ethics* (1912), *Philosophical Studies* (1922), and *Some Main Problems in Philosophy* (1953).

George Edward Moore was born in London. He graduated from Trinity College in Cambridge where he taught from 1911 until 1939. Moore was editor of the philosophical journal *Mind* from 1921 until 1947.

David H. Richter

Moore, George Augustus (1852-1933), was an Irish author. His novels show the influence of Honoré de Balzac's realism and Émile Zola's naturalism. *Confessions of a Young Man* (1888) is a clever portrayal of experimental painters in Paris. *Esther Waters* (1894) is a grim story of a servant girl's misfortunes. *Héloïse and Abelard* (1921), an account of a famous medieval love story, is his fictional masterpiece. It is considered one of the few great imaginative reconstructions of life in the Middle Ages.

Moore was born in County Mayo. He worked to es-

tablish a native Irish drama and helped bring about the Irish Literary Revival. He described his efforts in *Hail and Farewell* (1911-1914), a memoir. *Avowals* (1919) and *Conversations in Ebury Street* (1924) are autobiographical works in the form of dialogues. Sharon Bassett

Moore, Henry (1898-1986), is considered the greatest English sculptor of the 1900's. Moore used holes in his work to emphasize its three-dimensional quality. The holes create a sense of mass. Moore associated the openings with ". . . the mysterious fascination of caves in hillsides and cliffs." A good example is Moore's elmwood *Reclining Figure* (1936), which is reproduced in **Sculpture** (Modern international sculpture).

Much of Moore's later work is based on the human form. Moore's bronze *Family Group* (1949) shows how he simplified his human figures, treating the proportion freely. His figures are composed of flowing *convex* (curving outward) and *concave* (curving inward) forms that create rich contrasts of light and dark. A good example is his stone *Family Group* (1955).

Several of Moore's later works, such as his *Reclining Figure* (1965) at Lincoln Center in New York City, are outdoor pieces. These large bronze works combine the human form with cliff or rock formations. His abstract works, which resemble wood or stone objects shaped by natural forces, convey a mysterious quality.

Moore was born in Castleford, near Leeds. He attended the Leeds School of Art and the Royal College of Art in London. As a young sculptor, Moore was inspired by Mexican and African carvings, and his early work shows the simple and monumental quality of such art.

Moore, Marianne (1887-1972), ranks with Emily Dickinson among America's finest woman poets. Although some of her verse is difficult to understand, Moore crafted her poems superbly. She generally used poetic forms in which the controlling element is the number and arrangement of syllables rather than conventional patterns of meter.

Wide World
Marianne Moore

Moore's subjects—often birds, exotic animals, and other things in nature—may seem to limit her range, but she used them as symbols of honesty and steadfastness. These virtues mark her work, from *Poems* (1921) through *Complete Poems* (1967) and her critical prose collected in *Predilections* (1955). Her *Collected Poems* won the 1952 Pulitzer Prize for poetry. *The Complete Prose of Marianne Moore* was published in 1986, after her death.

Marianne Moore was born in St. Louis, and became a teacher and a librarian. As the editor of *The Dial* magazine from 1925 to 1929, Moore played an important part in encouraging young writers and publishing their work. William Harmon

See also **Poetry** (Rhythm and meter).

Moore, Thomas (1779-1852), an Irish poet, wrote the words for some of the best-loved songs in the English language. They include "Believe Me If All Those Endearing Young Charms," "The Last Rose of Summer," and "Oft in the Stilly Night." Moore wrote much light, serious, and satirical verse, and much prose. His works were as widely read in his day as the works of Lord Byron and Sir Walter Scott. But he is remembered today mostly for his verse set to music.

Moore was born in Dublin and graduated from Trinity College. He studied law for a time in London. His works include a translation of Anacreon's poems (1800); *Lalla Rookh* (1817), a romance; and a biography of Byron (1830). William Harmon

Moors is a term that commonly refers to Muslims who speak Arabic and live in northwestern Africa. The term also refers to Muslims of Spanish, Jewish, or Turkish descent who live in northern Africa. Muslims of Arab descent who live in Sri Lanka are also called *Moors. Moro,* another form of the word, refers to Muslims who live in the southern Philippines.

In ancient history, the Romans called the people of northwestern Africa *Mauri* and the region they lived in *Mauritania.* These people belonged to a larger group of African people called *Berbers.* Many of the Berbers became Muslims, and they adopted Arabic in addition to their own Berber language. They became known as Moors.

The Moors joined the Arabs in conquering Spain during the 700's. Much of what is regarded as Moorish civilization of the Middle Ages was largely Arabic. The Moors lost much of their land in Spain by the late 1200's. In 1492, Ferdinand and Isabella of Spain conquered Granada, the last Moorish kingdom in Spain. In 1500, they ordered the people of Granada to either become Christians or leave the region. Those who stayed were called *Moriscos.* James W. Brodman

Moose live in northern regions that have dense forests and many lakes and swamps. A cow moose and her calf, *left,* stroll along a shore. About 10 days after birth, a moose calf can travel with its mother. A bull moose, *right,* has heavy antlers that it sheds each year.

Moose is the largest member of the deer family. The largest kind of moose lives in Alaska. These moose stand up to 7½ feet (2.3 meters) high at the shoulder and weigh as much as 1,800 pounds (816 kilograms).

Moose inhabit northern forests throughout the world. In Europe, they are known as elk and live in northern Scandinavia and eastward through Siberia. In North America, moose live in Canada and Alaska and southward into the Rocky Mountains to Utah and Colorado. They also live in parts of Maine, Michigan, Minnesota, New Hampshire, and North Dakota.

The body of a moose. A moose has big shoulders that form a hump. Its long legs and broad hoofs make the moose a strong swimmer and help it to walk in marshy areas and through deep snow. Moose fur is brownish-black on the upper parts, and grayish-brown on the belly and lower legs. A flap of skin and fur, called a *bell,* hangs from the moose's throat. Most moose stand about 6½ feet (2 meters) high at the shoulder and weigh 800 to 1,400 pounds (360 to 640 kilograms).

The male moose, called a *bull,* has antlers. Moose antlers are shaped like the palm of a hand with many short, pointed fingers. Bulls shed their antlers every winter and then begin to grow new ones in the spring. A pair of moose antlers may measure 5 to 6 feet (1.5 to 1.8 meters) wide and weigh as much as 85 pounds (39 kilograms).

The life of a moose. The moose's mating season lasts a few weeks in the fall. A bull will roam about in search of a female moose, called a *cow.* Both bulls and cows make calling sounds in the mating season, and a bull will move toward a calling cow. If a bull finds another bull with a cow, the bulls fight with their antlers to see which one will mate with her. A mature bull may mate with several cows in one mating season. Moose calves are born in the spring. A cow has one, two, or, rarely, three calves. A calf's fur is reddish-brown. A calf stays with its mother until she chases it away the next spring before having her next calf.

Moose eat woody plants, especially twigs of willows and such shrubs as hazel, dogwood, and mountain maple. In addition, moose eat plants that grow under the surface of shallow water. They wade into streams and ponds and put their heads underwater to get a mouthful of plants. They usually raise their heads to watch for enemies while they chew.

Moose usually live alone and do not form herds as do North American elk and caribou. However, sometimes a group of three or four moose will stay in one spot if the food there is plentiful.

The chief enemies of moose are bears and wolves. A wolf pack or a bear will kill and eat a calf if the calf can be separated from its mother. Once a moose is full-grown, even a wolf pack cannot kill it unless it is old or weak. A moose does not begin to suffer from old age until it is about 12 years of age or more.

Although moose and white-tailed deer both live in forests and eat similar food, the two animals are usually not found together in great numbers. Deer carry a disease that rarely is fatal to them but often kills moose. This disease is caused by a tiny worm. The worm lives harmlessly on the surface of a deer's brain or spinal cord. In a moose, however, the worm burrows into the central nervous system and causes paralysis and, eventually, death.

Moose and people. Before Europeans came to North America, the moose was an important source of food for Indians. Settlers hunted moose until the animals became scarce in some areas. They also cut down most of the forests where moose lived. Eventually, restrictions were placed on moose hunting in many areas, and some forests were allowed to regrow. Today, moose have become numerous enough to allow some hunting in some areas.

Scientific classification. Moose belong to the deer family, Cervidae. They are *Alces alces.* L. David Mech

Moose International, Inc., is a fraternal and service organization. It has more than 1,700,000 members in over 3,900 lodges and chapters in the United States, Canada, the United Kingdom, and Bermuda. Members participate in many civic and philanthropic endeavors.

Moose International has its headquarters in Mooseheart, Illinois, near Chicago. There, it maintains Mooseheart, The Child City, which provides housing and education for children from broken or unstable families. The children are sponsored by Moose lodges. Moose International also runs Moosehaven, a retirement community in Orange Park, Florida, for dependent retired members.

Moose International emblem

The Moose conduct and fund many community service projects, such as the Youth Awareness Program, which trains teen-agers to give an antidrug message to children 4 to 9 years old. The Loyal Order of Moose, the branch for men, was founded in Louisville, Kentucky, in 1888. The women's branch, the Women of the Moose, was established in 1913. Critically reviewed by Moose International, Inc.

Moose Jaw (pop. 32,131) is a center for service industries and manufacturing in southern Saskatchewan. For location, see **Saskatchewan** (political map). Farmers and ranchers of the surrounding area send their products to Moose Jaw's grain elevators and stockyards. They also rely on the city for many service needs, such as health care. Industries in Moose Jaw include the manufacture of asphalt, chemicals, clothing, and food products. Although the origin of the name Moose Jaw is uncertain, it may have come from an Indian name for the Moose Jaw River, which flows through the town. Moose Jaw was chartered in 1884 and became a city in 1903. It has a mayor-council government. Adrian A. Seaborne

Mora, *MOH ruh,* **Juan Rafael** (1814-1860), served as president of Costa Rica from 1849 to 1859. He was called "National Hero" for defending Central America against an American adventurer, William Walker, in 1856 and 1857 (see **Walker, William**). Mora established public schools in Costa Rica and made elementary education compulsory. He encouraged the coffee industry, built public buildings, and gave Costa Rica its first national bank and its first street-lighting system. Rebels drove Mora from Costa Rica in 1859. He returned in 1860, but was defeated in a revolt and was executed at Puntarenas. Mora was born Feb. 18, 1814, in San José and died on Sept. 30, 1860. John A. Booth

Moraine, *muh RAYN,* is the earth and stones that a glacier carries along and deposits when the ice melts. Moraine also means a band of such material in a glacier or on its surface, or an uneven ridge of material deposited at the edge of the melting ice. On each side of a glacier in a mountain valley are rock fragments that have rolled onto the ice from nearby slopes. These rock fragments form a *lateral moraine.*

When two mountain glaciers unite, they form a compound glacier. The lateral moraines between them merge into a *medial moraine* along the middle of the compound glacier. When the ice front of a mountain glacier or continental ice sheet remains stationary, the melting ice deposits rocks carried by the glacier. These rocks form an *end moraine* or *terminal moraine,* an irregular ridge with hills and hollows. Some end moraines formed by the glaciers of the Pleistocene Epoch, which ended about 11,500 years ago, are long ranges of hills. A *ground moraine* is a thin, uneven layer of material deposited under the ice or at its edge as the ice retreats. A *recessional moraine* forms when a retreating glacier pauses for a long time. Donald F. Eschman

See also Glacier.

Moral education is instruction focused on questions of right and wrong. Moral education also includes the development of *values,* the standards by which people judge what is important, worthwhile, and good.

People receive moral education from many sources, including their family, church, friends, and teachers—and even television. Schools have always been involved in such education, either intentionally or unintentionally. For example, many stories for young readers include a moral lesson. During the 1970's, educators in the United States began to develop special teaching methods to help students deal with moral questions.

Methods of moral education

Schools use four chief methods in moral education. These methods are (1) inculcation, (2) values clarification, (3) moral development, and (4) value analysis. Some schools use a combination of these methods in an approach called *comprehensive moral education.*

Inculcation is an effort to teach children the values that educators believe lead to moral behavior. These include honesty, compassion, justice, and respect for others. One way of teaching such standards is to provide appropriate praise and punishment. Another means is to have teachers reflect the values in their own behavior.

Values clarification helps students develop their own values and moral standards by teaching them a decision-making process. The learning procedures stress setting goals, choosing thoughtfully from alternatives, and acting on one's own convictions.

Moral development helps students improve their ability to judge moral questions. This method is based on the theory that people progress from lower to higher stages of moral reasoning. According to the theory, people progress from making moral decisions based on self-interest, to seeking the approval of others, to following rules, to respecting the rights of others, and so on. At the highest moral level, an individual might oppose the laws of society if they conflict with moral principles that are even higher.

Educators stimulate moral development primarily by having students discuss difficult questions called *moral dilemmas.* One dilemma might be, "Should Heintz steal food to feed his starving family?" Educators also stimulate moral development by establishing *just schools,* in

which students govern themselves according to the principles of fairness and justice.

Value analysis helps students apply techniques of logic and scientific investigation to matters involving values. Teachers stress the importance of exploring all alternatives, of gathering and evaluating the facts, and of making a logical decision.

Arguments about moral education

Some people oppose the teaching of moral education in schools. Many of these individuals feel that only the family and church should provide such instruction. Others argue that moral education takes class time that should be used for such basic subjects as reading, writing, and mathematics.

Surveys indicate that most parents favor some form of moral education in schools. Supporters of such education argue that the family and church need help in teaching moral behavior. Many believe that schools in a democratic society must teach such values as hard work, honesty, fairness, cooperation, tolerance, and respect. Howard Kirschenbaum

Morale is the general attitude or outlook of an individual or a group toward a specific situation. It influences, and is influenced by, such factors as optimism, confidence, and determination. Morale may seriously affect both well-being and performance, and is closely related to what is called *esprit de corps.* When morale is "high," the sense of confidence of an individual or a group are generally good, resulting in a high level of performance. When morale is "low," performance is usually correspondingly poor.

Business executives, military officers, college deans, athletics coaches, and other leaders have learned to analyze the morale in their groups. They recognize that the level of morale is a decisive factor in determining group or individual achievement. Kenneth J. Gergen

See also **Alienation; Group dynamics.**

Morality play is a form of drama that flourished in the 1400's. The morality play developed from the mystery play, which dramatized Biblical events, and the miracle play, which dramatized the lives of saints. Morality plays were essentially dramatized sermons. Their general theme was the struggle between good and evil for the allegiance of the human soul.

The style of the morality play was usually allegorical, with the actors portraying such figures as Virtue, Vice, Riches, Poverty, Knowledge, Ignorance, Grace, or the Seven Deadly Sins. The play was centered on an allegorical figure sometimes called Mankind or Humanity. The figure represented common people and their souls. The antagonist of the Mankind figure was usually the Vice figure, who sometimes appeared as the Devil or under several other names. Often Vice was a comic figure full of tricks and disguises. But despite his comedy, Vice represented eternal damnation for the Mankind figure foolish enough to be deceived by him. Unlike the mystery plays, which were performed by amateurs, morality plays were performed by professional and sometimes traveling actors. Albert Wertheim

Moratorium, *MAWR uh TAWR ee uhm,* is a postponement of the time for payment of debts or financial obligations. It is accomplished by executive or legislative decree. The moratorium delays legal action on debts. But the moratorium does not release the debtor from the obligation to pay. It merely postpones the day the debt is due.

A moratorium has frequently been declared following a money panic, political or industrial upheaval, or national calamity, such as flood or earthquake. However, today moratorium refers mostly to the postponement of payment on commercial debts. The instruments of the credit system, such as bills of exchange, drafts, and bank deposits, are the kinds of things that are affected by a moratorium.

Moratoriums were used only on occasions of public disaster before World War I (1914-1918). Great Britain declared the first war moratorium in 1914 on bills of exchange that were due in London. President Franklin D. Roosevelt declared a moratorium in 1933 to save the financial system of the United States from complete collapse. During the 1980's, groups of commercial banks in industrial countries declared moratoriums on the repayment of loan principal by developing countries.

Joanna H. Frodin

Moravia, *moh RAY vee uh,* is a geographic region of the Czech Republic. The region covers 10,076 square miles (26,097 square kilometers) and has a population of about 4 million. Brno is the largest city of Moravia and the second largest of the Czech Republic. Only Prague has more people. Moravia's name in the Czech language is *Morava.*

Moravia lies in the eastern part of the Czech Republic. The region slopes southwest from the Carpathian and Sudeten Mountains to the Morava River. The Morava empties into the Danube River, one of the chief waterways of Europe.

Flat, fertile farmland makes up most of Moravia. The principal crops of the region include barley, corn, flax,

Czech Travel Bureau

Pernštejn Castle in Moravia has served as a fortress and as an aristocratic residence. The castle, completed in the early 1500's, is one of Moravia's major architectural monuments.

oats, rye, sugar beets, and wheat. Many farmers also raise beef and dairy cattle.

The Czech Republic's largest coal mines and an important industrial district are located around the city of Ostrava, in northern Moravia. The Ostrava area has large steelworks and other heavy industries. Moravian factories also produce chemicals, leather goods, machinery, shoes, textiles, and tractors.

Almost all the people of Moravia are Czechs, a Slavic people who speak the Czech language. Many Moravians belong to the Roman Catholic Church. Moravia has two universities and several technical schools.

After the A.D. 400's, Slavic tribes settled in Moravia. During the 800's, these tribes united with other Slavic tribes and formed the Great Moravian Empire, which included a large part of central Europe. Beginning in the late 800's, the Magyars (Hungarians) invaded the Great Moravian Empire, and in time they destroyed it.

In the early 900's, Moravia became part of the territory ruled by the Duke of Bohemia. In 1526, Bohemia and Moravia came under the rule of the Habsburg family of Austria. The Habsburgs ruled the Czechs for almost 400 years.

In October 1918, shortly before World War I ended, the independent republic of Czechoslovakia was established, with Moravia as one of its provinces. During World War II (1939-1945), German troops occupied Czechoslovakia. The Germans set up Moravia and Bohemia as a single protectorate within Germany. This protectorate was dissolved after Soviet and United States forces drove the German troops from Czechoslovakia in 1945. In 1949, Czechoslovakia replaced its provinces, including Moravia, with smaller administrative units. In 1993, the independent countries of the Czech Republic and Slovakia were created to replace Czechoslovakia. Moravia became part of the Czech Republic. Vojtech Mastny

WORLD BOOK map

Moravia, which is a region in the eastern part of the Czech Republic, has industrial cities, rich mineral deposits, and fertile farmland. Brno is the largest city.

Moravian Church, *maw RAY vee uhn,* is a Protestant denomination that was formed after the death of religious reformer John Hus in Bohemia. In 1457, some supporters of the martyred Hus organized themselves as the *Unitas Fratrum* (Unity of Brethren). They stressed the sole authority of the Bible; simplicity in worship; receiving the Lord's Supper in faith without authoritative human explanation; and disciplined Christian living. Despite suppression, the Brethren flourished and were an important religious force by the time of Martin Luther. See **Brethren; Hus, John.**

The Brethren suffered great persecution during the Thirty Years' War (1618-1648). The group revived during the Pietist movement in Germany in the early 1700's. Pietists were Christians—mainly Lutherans—who wanted to return to the simple life of the early Christians. Beginning in 1722, refugees from Moravia under the leadership of Count von Zinzendorf reorganized the church. It then became known as the Moravian Church. The group built Herrnhut, a town located on Count von Zinzendorf's estate in Saxony. Herrnhut became the base for the missionary activity of the Moravian Church throughout the world, especially among developing countries. The Moravian Church has always been noted for its missionary work. As a result, most Moravians live in Africa or the Caribbean area. Today, the denomination has about 700,000 members.

Moravians first immigrated to America in 1735. The church has two headquarters—in Bethlehem, Pennsylvania, and Winston-Salem, North Carolina. The church has three orders of the ministry—bishops, presbyters, and deacons. Provincial and district *synods* (conferences) of ministers and the laity administer the church.

Moray. See **Eel.**

Mordant, *MAWR duhnt,* is a chemical that combines with dyes to prevent them from dissolving easily. The dye alone might wash out, but the compound formed by the dye and the mordant will not, so the color is long lasting. Common mordants include salts of chromium, iron, aluminum, tin, or other metals. These are basic or metallic mordants. They are used with two kinds of dyes, acid dyes and direct dyes. Tannic acid, lactic acid, and oleic acid are acid mordants. They combine with a group of dyes called basic dyes. The compounds of basic mordants with dyes are called *lakes.* When alizarin, an acid dye, is mordanted with a basic aluminum salt, it colors cotton cloth a bright red, called *Turkey red.* See also **Lake** (dye). Howard L. Needles

More, Saint Thomas (1477?-1535), was a great English author, statesman, and scholar. He served as lord chancellor, the highest judicial official in England, from 1529 to 1532. But More resigned because he opposed King Henry VIII's plan to *annul* (cancel) his marriage to the queen. More was beheaded in 1535 for refusing to accept the king as head of the English church. More has become an example of the individual who places conscience above the claims of *secular* (nonreligious) authority. The Roman Catholic Church declared him a saint in 1935. In 2000, the church named him patron saint of statesmen and politicians.

Detail of an oil portrait by Hans Holbein the Younger, the Frick Collection, New York

Saint Thomas More

His life. More was born in London, probably in 1477 but perhaps in 1478. He studied at Oxford University. More began his legal career in 1494, and became an undersheriff of London in 1510. By 1518 he had entered the service of King Henry VIII as royal councilor and ambassador. He was knighted and made undertreasurer in 1521, and was chancellor of the Duchy of Lancaster from 1525 to 1529.

More became lord chancellor after Cardinal Wolsey

was dismissed late in 1529. At that time, Henry VIII was engaged in a bitter battle with the Roman Catholic Church. He wanted to annul his marriage to Catherine of Aragon so he could marry Anne Boleyn. More resigned his office because he could not support the king's policy against the pope. In April 1534, More was imprisoned for refusing to swear to the Oath of Supremacy, the preamble to a law called the Act of Succession. The oath stated that Henry VIII ranked above all foreign rulers, including the pope. More was convicted of high treason on *perjured* (falsely sworn) evidence and was beheaded on July 6, 1535.

Character and writings. More's personality combined intense concern for the problems of his day and spiritual detachment from worldly affairs. He was a devoted family man, and lived a plain, simple private life. He was famed for his merry wit. Yet to the people of his day, More was a contradictory figure—he was merriest when he seemed saddest and was saddest when he appeared most happy. He was a patron of the arts. His friends included the humanist Erasmus and the artist Hans Holbein.

More's sympathetic philosophy is best reflected in *Utopia* (written in Latin in 1516). *Utopia* is an account of an ideal society, with justice and equality for all citizens. This masterpiece gave the word *utopia* to European languages. More also produced much English and Latin prose and poetry. He wrote his finest English work, *A Dialogue of Comfort Against Tribulation,* while in prison. His other works include *The History of King Richard III* (written in English in 1513?) and a series of writings in Latin in which he defended the church against Protestant attacks. Gary A. Stringer

Mores, *MAWR ayz,* are customs that reflect a society's ideas about right and wrong. Examples of mores include the prohibitions in many societies against murder, cannibalism, and *incest* (sexual relations between closely related persons). People who violate the mores of their society face disapproval and punishment. The term *mores* comes from a Latin word that means *customs.*

Most people believe the well-being of their society depends on the enforcement of its mores. Many societies have enacted laws that reflect their own mores (see **Law** [The development of law]). Mores are a type of *folkway,* but not all folkways are considered as important as mores to the society's welfare. Examples of less strongly held folkways include wedding and funeral traditions and table manners. The violation of such folkways produces only a mild reaction, such as surprise or scorn.

The term *mores* was introduced in English by William Graham Sumner, an American sociologist, in his book *Folkways* (1906). Sumner pointed out that mores vary from one society to another. In most cases, each society believes that its own mores are the most natural and desirable ones. Sumner called this belief *ethnocentrism.*

Most mores remain unchanged from generation to generation, but some change over a period of time. For example, many people in the United States once believed in the segregation of whites and blacks. Today, however, many people think all individuals should have equal access to housing, education, jobs, and public facilities. Michael Moffatt

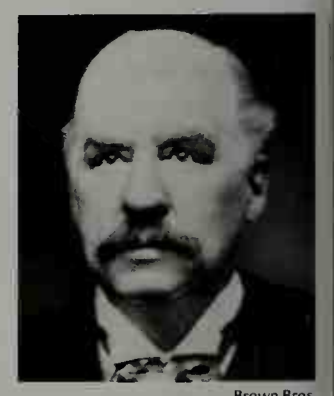
Morgagni, *mawr GAH nyee,* **Giovanni Battista,** *jaw VAHN nee baht TEES tah* (1682-1771), an Italian anatomist and pathologist, became known as "the father of pathological anatomy." He discovered and described many diseases of the heart and blood vessels. Morgagni's book, *On the Seats and Causes of Diseases* (1761), became a landmark in the history of pathology (see **Pathology**). Morgagni believed that disease results from a breakdown in tissues and organs, producing abnormal changes that can be seen during an autopsy.



Morgagni graduated from the University of Bologna. He became a professor of theoretical medicine at the University of Padua in 1712. He was appointed as the first professor of anatomy in 1715. Morgagni was born in Forlì, Italy. Matthew Ramsey

Morgan is the family name of three great American bankers.

Junius Spencer Morgan (1813-1890) founded the Morgan financial empire. As a young man, he made a fortune in the dry-goods business, and in 1854 he became a member of the London banking firm of George Peabody and Company. The company's name later was changed to J. S. Morgan and Company, and the firm became a famous international banking house with headquarters in London. Morgan was born in what is now Holyoke, Massachusetts.

John Pierpont Morgan (1837-1913), a son of Junius Spencer Morgan, became one of the greatest financiers in the United States. He joined his father's banking firm in 1856. Morgan was a member of the firm of Dabney, Morgan & Company from 1864 to 1871. In 1871, Morgan and the Drexel family of Philadelphia established the firm of Drexel, Morgan & Company. Morgan reorganized the firm under the name of J. P. Morgan & Company in 1895.

Morgan's firm became a leader in financing American business and in marketing bond issues of the U.S. government. It also sold bonds of the British government. Morgan helped organize the United States Steel Corporation in 1901. He was active in financing the International Harvester, American Telephone and Telegraph, and General Electric companies. Morgan and his associates served as directors of corporations, banks, railroads, public utility companies, and insurance firms. In 1912, he was investigated by a congressional committee because of his financial power, but nothing discreditable was revealed.

Brown Bros.
John Pierpont Morgan

After the panic of 1893, Morgan helped reorganize many railroads, including the Northern Pacific, Erie, Southern, and the Philadelphia and Reading. In 1904, the Supreme Court of the United States dissolved the Northern Securities Company because it violated the Sherman Antitrust Act. Morgan and other financiers had created the company in order to control key railroads in the West.

In 1895, Morgan's firm sold all of a $62-million government bond issue. The sale ended a gold shortage in the U.S. Treasury. During the panic of 1907, Morgan loaned money to banks to keep them from closing.

Morgan made many gifts to education and charity. He founded the Lying-in Hospital in New York City and gave a large sum to the Harvard Medical School. Morgan was an ardent Episcopalian and gave a substantial share of the funds to build the Cathedral of Saint John the Divine in New York City.

He was a great art collector and gave many valuable pictures, statues, and books to American libraries and museums. Some of his most famous collections were loaned to the Metropolitan Museum of Art in New York, which he helped found. Morgan was a famous yachtsman. He was active in defending the America's Cup in international yachting several times.

Morgan was born in Hartford, Connecticut. He attended the University of Göttingen in Germany.

John Pierpont Morgan, Jr. (1867-1943), was the son of John Pierpont Morgan. When his father died in 1913, Morgan took over many of the financial posts J. P. Morgan had held. Morgan succeeded his father as chairman of the board of United States Steel.

Morgan's firm became an official wartime purchasing agent for the United Kingdom in the United States in 1914. In this position, he placed contracts for the manufacture of food and munitions. The J. P. Morgan Company handled most of the postwar international loans, including many dealing with reparations. Morgan was appointed a member of the commission to revise the Dawes Plan in 1929 (see **Dawes Plan**).

Like his father, Morgan made large gifts to education and the arts. In 1923, he dedicated his father's library as an institution of research. Under the terms of the gift, the library will be kept intact as a complete unit until March 31, 2013, a hundred years from the date of his father's death. In 1920, Morgan gave his house in London to the United States for use as the residence of the U.S. ambassador. Morgan was born in Irvington, New York, and graduated from Harvard University. W. H. Baughn

Morgan, Daniel (1736-1802), served as an American officer in the Revolutionary War. He joined the Revolutionary forces in 1775 as a captain. He volunteered to go with Benedict Arnold on his expedition to Quebec and was taken prisoner there. On his release in 1776, he became a colonel in charge of a Virginia regiment. He organized a corps of sharpshooters in 1777 that helped General Horatio Gates in his battles against General John Burgoyne. Morgan resigned from the army in 1779. But he was recalled in 1780 and became a brigadier general. He commanded the American troops at the victory at Cowpens, South Carolina, in 1781.

After the war, he helped put down the Whiskey Rebellion in 1794 in western Pennsylvania (see **Whiskey Rebellion**). He served as a Federalist from Virginia in the U.S. House of Representatives from 1797 to 1799. Morgan was probably born in Hunterdon County, New Jersey. Paul David Nelson

Morgan, Garrett Augustus (1877-1963), was an American inventor. He developed a number of devices, including versions of the gas mask and traffic light.

Morgan developed a gas mask in 1912. His device included an airtight canvas hood that was worn over the head. The hood was connected to a special breathing tube that hung to the ground. Many police departments and fire departments throughout the United States became equipped with Morgan's gas mask. In 1916, Morgan used his device to rescue more than 20 workers who were trapped in a smoke-filled water tunnel in Cleveland.

Ebony Magazine

Garrett Augustus Morgan

Morgan patented his traffic light in 1923. His device looked much different from the traffic signals used today. However, like modern traffic signals, the device Morgan patented had red, yellow, and green lights. Soon after Morgan received the patent for his traffic light, he sold the rights to the General Electric Company for $40,000.

Morgan was born in Paris, Kentucky. He moved to Cleveland in 1895. Raymond W. Smock

Morgan, Sir Henry (1635?-1688), was the most famous English *buccaneer* (pirate). In his day, England and Spain were rivals for trade and colonies. Morgan raided Spanish ships and towns in Spain's colonies in the West Indies, Central America, and South America. In 1671, he caused the destruction of Panama City, Panama, the largest Spanish city in Central America.

Early career. Morgan was born in Wales. Little is known of his early life. In 1655, he arrived in the West Indies as a soldier with an English expedition. This expedition captured the Spanish colony of Jamaica. By 1666, Morgan had become a buccaneer. Thomas Modyford, the new English governor of Jamaica, thought the buccaneers were Jamaica's best defense, and he directed them to attack the Spaniards.

In 1668, Morgan led about 500 English buccaneers in a raid on Portobelo, Panama. Morgan proved his skills as a commander by capturing the city. At one point, he used captives, including priests and nuns, as a human shield while attacking a fortress.

In 1669, Morgan gathered about 500 buccaneers and eight ships for a raid on Maracaibo, Venezuela. On his way home to Jamaica, he easily defeated three Spanish warships that had been sent to capture him.

Morgan returned to Jamaica to discover that England and Spain were negotiating a peace treaty. With the

treaty nearly approved, Modyford hesitated to permit the buccaneers to attack the Spanish again. However, after a Spanish attack, and before news of the signing of the treaty had reached Jamaica, he allowed Morgan to sail again.

Attack on Panama. In December 1670, Morgan headed for Panama in his final and most famous raid. He led a force of 38 ships and about 2,000 men. He captured several towns and finally faced the Spanish army just outside Panama City in 1671. The Spaniards stampeded a herd of cattle at the buccaneers, but Morgan's men scattered the cattle and slaughtered the Spanish army. Some Spaniards then set fires in Panama City in hopes of slowing the buccaneers' progress. The fires got out of control and destroyed the city. The Spaniards had earlier moved their wealth out of the city, and the buccaneers found little loot to share.

Shortly after Morgan reached Jamaica in 1671, Sir Thomas Lynch succeeded Modyford as governor of Jamaica. The English government had decided to replace Modyford because of his support of the buccaneers. The new governor arrested Morgan for his attack on Panama and sent him to England for trial. But King Charles II forgave Morgan and knighted him in 1674. Morgan was appointed deputy governor of Jamaica in 1674 and served until 1683. Robert C. Ritchie

Morgan, John Hunt (1825-1864), a Confederate general, led a famous group of soldiers called Morgan's Raiders during the American Civil War (1861-1865). His troops, volunteer cavalrymen, raided public property, burned bridges, took horses, and captured railroad supplies. They also caused severe losses among Union troops. Morgan never commanded over 4,000 men, but it is said he captured as many as 15,000 soldiers.

In 1863, Morgan was ordered to invade Kentucky and draw General William S. Rosecrans's Union army from Tennessee. Morgan went farther than he was ordered. He broke through the federal lines in Kentucky and crossed the Ohio River into Indiana. A flood caused the river to rise, and Morgan could not return to Confederate territory. He was captured in July 1863 and was imprisoned in Columbus, Ohio.

Morgan escaped the next November and continued his raids. He was defeated in Kentucky, in June 1864. He went to Greeneville, Tennessee, where he was surrounded and shot by Union troops in September 1864. Morgan was born in Huntsville, Alabama. He fought in the Mexican War in 1846 and 1847. John F. Marszalek

Morgan, Julia (1872-1957), was one of the first prominent American female architects. Morgan designed more than 700 buildings in a variety of styles during her 47-year career. Her best-known work is San Simeon (1919-1939), the extravagant California mountain-top estate of American publisher William Randolph Hearst.

Morgan designed many houses and churches in the San Francisco Bay area. Her designs contributed to the Bay Area style of architecture, which featured low, horizontal shapes and much use of wood, stone, and other natural materials in earth colors. Morgan also designed churches, hospitals, schools, and stores in several historically based styles. In addition, she designed many YWCA club buildings throughout California, and a few in Hawaii and Utah.

Morgan was born in San Francisco and grew up in Oakland, California. She graduated from the University of California at Berkeley in 1894 with a degree in engineering. In 1902, she became the first woman to graduate from the noted École des Beaux-Arts school of architecture in Paris. Morgan set up her own office in San Francisco in 1904. Leland M. Roth

Morgan, Justin (1748-1798), owned and gave his name to a horse that was the original stallion of the breed of Morgan horses. The breed became famous for its strength, endurance, and speed (see **Horse** [Saddle horses; picture]). When the horse was a colt, Morgan received it from a farmer in payment of a debt. This unusual stallion died in 1821 at the age of 29. Morgan was born in West Springfield, Massachusetts. He moved to Randolph, Vermont, in 1788 and became a schoolteacher, singing master, and town clerk. Steven D. Price

Morgan, Lewis Henry (1818-1881), was an American anthropologist who founded the comparative scientific study of kinship systems. He studied family relationships of American Indians and other peoples to determine their similarities and differences. Unlike most other anthropologists of his time, he learned many of his facts firsthand by traveling and by observing living Indians.

Morgan also became famous for his theory of social evolution. According to this theory, the history of human culture was a process of *evolution* (gradual development) from lower to higher forms. Morgan believed that people pass through three stages of development: (1) savagery, (2) barbarism, and (3) civilization. So-called primitive peoples, whose technology was less advanced than that of Western nations, supposedly represented the earlier phases of evolution.

Morgan was born near Aurora, New York, and became a lawyer. He began anthropological research after joining a club dedicated to studying Indian ways of life. He never held an academic post but achieved widespread recognition for his studies. His books include *Systems of Consanguinity and Affinity of the Human Family* (1871) and *Ancient Society* (1877). Igor Kopytoff

Morgan, Thomas Hunt (1866-1945), an American geneticist, won the 1933 Nobel Prize in physiology or medicine for his work on heredity described in *The Theory of the Gene* (1926). He showed through his experiments that certain characteristics are transmitted from generation to generation through genes (see **Heredity** [The birth of genetics]).

Morgan studied the laws of heredity by using the fruit fly (*Drosophila melanogaster*) for experiments in breeding. His research clarified the physical basis for the linkage and recombination of hereditary traits. He was the first to explain sex-linked inheritance, that some traits pass to only one or the other sex. Morgan and his associates proved that genes are arranged on the chromosomes in a fixed linear order (see **Chromosome**).

Morgan began his experiments at Columbia University, where he was professor of biology from 1904 to 1928.

He was director of the William G. Kerckhoff Biology Laboratory at the California Institute of Technology from 1928 to 1941. He wrote *Evolution and Genetics* (1925), *Experimental Embryology* (1927), and was coauthor of *The Mechanism of Mendelian Heredity* (1915).

Morgan was born in Lexington, Kentucky. He studied at the University of Kentucky, McGill University, the University of Edinburgh, and received his Ph.D. from Johns Hopkins University. His many honors included membership in the Royal Society (1919). Alan R. Rushton

Morgan's Raiders. See Morgan, John Hunt.

Morgantown, West Virginia (pop. 25,879), is the home of West Virginia University. The city's factories make brass plumbing fixtures, hand-blown glass, and textiles. Limestone quarries and two of the world's largest coal mines are nearby. Morgantown lies on the banks of the Monongahela River, 72 miles (116 kilometers) south of Pittsburgh (see **West Virginia** [political map]). Colonel Zackquill Morgan founded the city about 1766. It was known as Morgan's Town when it was chartered in 1785. It has a council-manager government. John Samsell

Morgenthau, *MAWR guhn THAW,* **Henry, Jr.** (1891-1967), served as United States secretary of the treasury from 1934 to 1945 under Presidents Franklin D. Roosevelt and Harry S. Truman. Morgenthau, who was one of Roosevelt's most trusted economic advisers, helped create important financial legislation in the 1930's. During World War II (1939-1945), he organized the Victory Bond campaign that raised more than $200 billion.

Morgenthau lived near Roosevelt's Hyde Park (New York) estate, and they were close friends. When Roosevelt became governor of New York in 1929, he named Morgenthau head of his Agricultural Advisory Commission. Morgenthau served briefly in 1933 as chairman of the Federal Farm Board and then as governor of the Farm Credit Administration. He was undersecretary of the treasury before he was named secretary in 1934.

During World War II, he proposed the Morgenthau Plan for Germany. It would have eliminated most of Germany's heavy industries and ended German military power. It was never adopted. Morgenthau took a leading part in the 1944 Bretton Woods (New Hampshire) international monetary conference. He was born in New York City. Alonzo L. Hamby

Morison, Samuel Eliot (1887-1976), was an American historian, teacher of history, and winner of two Pulitzer Prizes. His *Admiral of the Ocean Sea,* a life of Columbus, won the prize in 1943, and his *John Paul Jones* won it in 1960. His other books include *History of United States Naval Operations in World War II* in 15 volumes (1947-1962), *The Intellectual Life of Colonial New England* (1960), *One Boy's Boston* (1962), *The Oxford History of the American People* (1965), *The European Discovery of America: The Northern Voyages* (1971), and *The European Discovery of America: The Southern Voyages* (1974).

Morison was born in Boston and was educated at Harvard University and in Paris. From 1915 to 1955, he taught history at Harvard. He served in World War I (1914-1918) and World War II (1939-1945). Morison was elected to the American Academy of Arts and Letters in 1963. Robert C. Sims

Morisot, *maw ree ZOH,* **Berthe,** *bairt* (1841-1895), was a French painter and an important member of the impressionist movement. Many of her pictures portray women, often with their children, in scenes of everyday domestic life. She painted such subjects in a light, delicate style. Morisot also painted landscapes, many with women and children. In addition to her oil paintings, she was noted for her water colors and pastel works.

Morisot was born in Bourges and moved to Paris in 1851. She studied with the noted landscape artist Camille Corot in the 1860's. Morisot first exhibited in the Salon of 1865. She met the artist Edouard Manet in 1868, and they became close friends. He painted many portraits of her, and she married his brother in 1874. She and Manet influenced each other's work in the 1870's.

Morisot participated in the first Impressionist show in 1874. After 1880, her work was influenced by the style and colors of the Impressionist artist Pierre Auguste Renoir. Ann Friedman

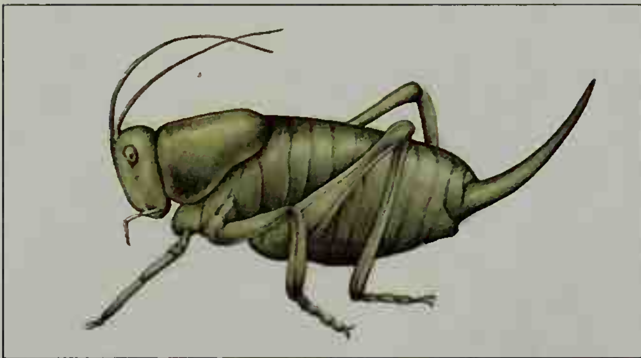
Oil painting (1870); National Gallery of Art, Washington, D.C., Chester Dale Collection

A typical Morisot painting, *The Mother and Sister of the Artist,* portrays two women in a scene from everyday life.

Morley, Thomas (1557 or 1558-1602), was an English composer of the Renaissance period. He is best known for his lighthearted unaccompanied vocal pieces known as *madrigals* (see **Madrigal**).

Morley's most popular madrigal is "Now Is the Month of Maying," with its nonsense refrain "Fa la la." Another popular Morley song is "It Was a Lover and His Lass," with words from William Shakespeare's comedy *As You Like It.* Morley's songs for two voices, called *canzonets,* are still used as models by music theory students.

Morley was born in Norwich. He was educated at Oxford University and became a noted music teacher. In 1597, he published a composition textbook, written as a dialogue, which tells us much about how music was taught and written in his time. Morley also made ar-



rangements for a *consort,* a group of instruments used in the theater of his day. Joscelyn Godwin

Mormon cricket is not really a cricket but belongs to the family of katydids and long-horned grasshoppers. It can be very harmful to crops. The Mormon cricket lives in the Western United States and as far east as Kansas.

Mormon crickets are brown, black, or green and grow about 2 inches (5 centimeters) long. They have small wings but cannot fly. In summer, the female Mormon cricket lays its eggs one at a time in the ground. The young hatch the next spring and are full-grown by summer. Farmers use poisonous powder and baits to kill Mormon crickets. In 1848, a swarm threatened to ruin the crops of the Mormons in Utah. But flocks of gulls suddenly appeared and ate the insects.

Betty Lane Faber

Scientific classification. The Mormon cricket belongs to the family Tettigoniidae. It is *Anabrus simplex.*

WORLD BOOK illustration by Shirley Hooper, Oxford Illustrators Limited

The Mormon cricket is very destructive to crops in the western United States. It has small wings but cannot fly.

Mormons is the name commonly given to members of The Church of Jesus Christ of Latter-day Saints. They are so called because of their belief in the *Book of Mormon.* They claim that the Church as established by Christ did not survive in its original form, and was restored in modern times by divine means through a modern prophet, Joseph Smith. Thus, they believe their church is the true and complete church of Jesus Christ restored on earth. Mormons are more correctly called *Latter-day Saints,* using the word "saint" in its Biblical sense to mean any member of Christ's church.

The church has almost 7 million members. Many Mormons live in the western United States, and church headquarters are in Salt Lake City, Utah. The church is also established in most other countries of the world.

Several other churches accept the *Book of Mormon,* but are not associated with the church described in this article. The largest of these is the Community of Christ (formerly called the Reorganized Church of Jesus Christ of Latter Day Saints), which has headquarters in Independence, Mo.

Church doctrines

Mormon beliefs are based on ancient and modern revelations from God. Many of these revelations are recorded in scriptures. These scriptures include the Bible, the *Book of Mormon, Doctrine and Covenants,* and the *Pearl of Great Price.*

Mormons regard the Bible as the word of God, but they believe that it is not a complete record of all that God said and did. The *Book of Mormon* is a history of early peoples of the Western Hemisphere. Mormons teach that the *Book of Mormon* was divinely inspired, and regard it as holy scripture. The *Book of Mormon* was translated by Joseph Smith from golden plates which he said he received from the angel Moroni. *Doctrine and Covenants* contains revelations made by God to Smith. The *Pearl of Great Price* contains writings of Smith and his translation of some ancient records.

Mormons believe in a unique concept of God. They teach that this concept was revealed by God through Joseph Smith and other prophets. Mormons believe that the Supreme Being is God the Father, who is a living, eternal being having a glorified body of flesh and bone. The human body is made in the image of God.

Mormons teach that God the Father created all people as spirit-children before the earth was made. They regard Jesus Christ as the first spirit-child the Supreme Being created. They believe that Christ created the world under the direction of God the Father. This is why Mormons also refer to Christ as the Creator. Jesus Christ came down to earth and was born of the Virgin Mary. He was the only one of God's spirit-children begotten by the Father in the flesh. He is divine.

Jesus Christ died on the cross for the sins of all humanity and brought about the resurrection of all. He lives today as a resurrected, immortal being of flesh and bone.

God the Father and Jesus Christ are two separate be-

Detail of an oil painting on canvas (1966) by Ken Riley; Church Office Building, Salt Lake City, Utah (The Church of Jesus Christ of Latter-Day Saints)

Joseph Smith, *left,* the founder of the Mormon Church, said he received engraved plates from the angel Moroni. Smith translated them into the scriptures called the *Book of Mormon.*

ings. Together with the Holy Ghost, they form a Trinity, Godhead, or governing council in the heavens. The Holy Ghost is a third personage, but is a spirit without a body of flesh and bone.

Mormons claim that their doctrine is the one which Jesus and His apostles taught. They believe that the first principles and ordinances of the gospel are faith in Jesus Christ; repentance; baptism by immersion for the remission of sins; and the laying on of hands for the gift of the Holy Ghost. They believe that a person must be called of God by those who have the authority in order to preach the gospel and to administer its ordinances.

Mormons believe in life after death and in the physical resurrection of the body. The spirit, awaiting the resurrection of the body, continues in an intelligent existence. During this time, persons who did not know the gospel in life may accept it after death. Mormons believe, for this reason, that living persons can be baptized on behalf of the deceased. In this ceremony, a living Mormon acts as a representative of the dead person and is baptized for that person. Other rites are performed for the dead.

Since Mormons believe in life after death, they believe that family life continues after death. Marriages performed in a Mormon temple are for eternity, and not just for this life. Mormons believe in a final judgment in which all people will be judged according to their faith and works. Each person will be rewarded or punished according to merit.

Some Mormons practiced *polygamy* (the practice of a man having more than one wife at the same time) as a religious principle during the mid-1800's. But the church outlawed the practice in 1890 after the Supreme Court of the United States ruled it illegal.

They believe in upholding the civil law of the country in which they are established. For example, they believe the Constitution of the United States is an inspired document. Mormons in the United States are urged by their religion to uphold its principles.

Church organization

Mormons regard the organization plan of their church as divinely inspired. They have no professional clergy. But all members in good standing, young and old, can participate in church government through several church organizations. A body called the General Authorities heads the church. It consists of the President and two counselors; the Council of the Twelve Apostles; the Patriarch of the church; the First Quorum of the Seventy; and the three-member Presiding Bishopric.

Under the General Authorities are area leaders and then regional and local organizations called stakes and wards. Each *stake* (diocese) is governed by a president and two counselors, who are assisted by an advisory council of 12 men. A stake has between 2,000 and 10,000 members. A *ward* (congregation) is governed by a bishop and two counselors. Wards have an average of 500 to 600 members.

Worthy male members of the church may enter the priesthood, which is divided into two orders. The *Aaronic* (lesser) order is for young men 12 to 18 years old. The *Melchizedek* (higher) order is for men over 18. Each order is subdivided into *quorums* (groups). Mormons believe that the priesthood provides authority to act in God's name in governing the church and in performing religious ceremonies.

Several auxiliary organizations assist the priesthood. The Sunday School, the largest auxiliary organization, provides religious education for adults and children. The Women's Relief Society helps the sick and the poor, and directs women's activities. The Young Men and Young Women organizations provide programs for

Mormon pioneers left Nauvoo, Ill., in 1846, on the way west to the valley of the Great Salt Lake in Utah. The Mormons had established the city of Nauvoo only seven years earlier. But it became a hotbed of anti-Mormon feeling. Many of the saints were killed and their homes and fields burned. After Joseph Smith's death, Brigham Young led the pioneers.

Paul Markow & Associates from FPG

teen-agers. The Primary Association sponsors classwork and recreation for children 3 to 11 years old.

The church operates an extensive educational system. It provides weekday religious education for high school students in about 1,900 *seminaries* located near public high schools in 42 states and six foreign countries. The church conducts 66 weekday religious *institutes* for Mormon students near college campuses. It also maintains fully accredited colleges and universities in Utah, Idaho, and the Pacific Islands. Best known of these is Brigham Young University in Provo, Utah.

Mormons assist aged, handicapped, and unemployed members through a voluntary *welfare program.* Projects directed by the wards and stakes help the poor.

Voluntary contributions from members and income from church-operated businesses support the church. Most members give a *tithe* (one-tenth of their annual income) to the church. Thousands of young men and women and retired people work from 18 to 24 months in a worldwide missionary program without pay.

History

Revelations. During the early 1800's, Joseph Smith, the son of a New England farmer, received a series of divine revelations. According to Smith's account, God the Father and Jesus Christ appeared to him near Palmyra, N.Y., in 1820. They advised him not to join any existing church and to prepare for an important task. Smith said he was visited by an angel named Moroni three years later. Moroni told him about golden plates on which the history of early peoples of the Western Hemisphere was engraved in an ancient language. In 1827, Smith received the plates on Cumorah, a hill near Palmyra. His translation of the plates, called the *Book of Mormon,* was published in 1830. Smith and his associates founded the church on April 6, 1830. It grew rapidly, and had 1,000 members by the end of the first year.

Mormons in the Middle West. Mormon communities were established at Kirtland, Ohio, and Independence, Mo., during the early 1830's. Smith moved the church headquarters to Kirtland in 1831, and the town was the center of the church for almost eight years. He instituted the basic organization and many of the present doctrines there. The first Mormon temple was completed there in 1836.

The 1830's were years of growth, but serious problems arose at the same time. Disputes among some church members themselves, the collapse of a Mormon bank in 1837, and conflict with non-Mormon neighbors broke up the Kirtland community. In 1838, Smith and his loyal followers moved to Missouri, and joined other Mormons there. But trouble again arose. The Missouri Mormons had been driven from Independence in 1833, many settling in a town called Far West, in northern Missouri. In the fall of 1838, mobs attacked the Mormons in several of their settlements. In the "massacre at Haun's Mill," 17 Mormons, including some children, were killed. Joseph Smith and other leaders were

arrested on what Mormons believe were false charges. Ordered out of Missouri, more than 5,000 Mormons fled to Illinois in late 1838 and early 1839. Smith escaped from prison in the spring of 1839 and rejoined his people in Illinois.

They founded the city of Nauvoo, which became one of the state's largest cities. The rapid growth of Nauvoo, and the important part Mormons played in state politics made non-Mormons suspicious and hostile again. One faction set up a newspaper to fight Smith, who had become a candidate for president of the United States. The paper was destroyed, and Smith was blamed for it. He, his brother Hyrum, and other leaders were arrested and jailed. On June 27, 1844, a mob attacked the jail. Smith and his brother were shot and killed.

The Mormons in Utah. Brigham Young became the next church leader. Mobs forced the Mormons out of Illinois in 1846. Joseph Smith had planned to move his people to the Great Basin in the Rocky Mountains. This plan was now put into effect by Young. In 1847, Young led the advance party of settlers into the Great Salt Lake valley. The population of the region grew rapidly, and by 1849, the Mormons had set up a civil government. The Mormons applied for admission to the Union as the *State of Deseret,* but Congress created the Territory of Utah in 1850 instead, and appointed Young governor.

Trouble with non-Mormons began again. It was falsely reported in Washington, D.C., that the Mormons were rebelling. Anti-Mormon public opinion caused President James Buchanan to replace Young with a non-Mormon governor and to send troops to Utah in 1857. The trouble that followed has been called the Utah War or the Mormon War. The conflict ended in 1858 when Young accepted the new governor and President Buchanan gave full pardon to all concerned.

The number of Utah settlements increased until the territory's population reached 140,000 in 1877. Congress continued to oppose the practice of polygamy, and the church outlawed the practice in 1890. A Mormon ambition was realized in 1896 when Utah was admitted to the Union as the 45th state.

Mormons today have won a reputation as a temperate, industrious people who have made their churches monuments to thrift and faith. Their meeting houses are in many ways model community centers. They include facilities for worship, learning, and recreation. There are 121 temples built or planned worldwide. The temples are devoted entirely to religious ceremonies, and are open only to faithful Mormons. All other Mormon meeting places, chapels, and recreation halls are open to the general public.

The promotion of music and the arts has long been important to the Latter-day Saints. The 325-voice Mormon Tabernacle Choir in Salt Lake City is famous for its broadcasts, telecasts, and concert tours. The choir, now more than a hundred years old, has been heard on United States radio networks since 1929.

Morning-glory is the name of a family made up mainly of climbing plants. Garden morning-glories are among the best-known plants in this group. Others are the *bindweed, jalap, moonflower, scammony,* and *sweet potato.* The morning-glory grows rapidly and twines about nearby objects. Its vines grow from 10 to 20 feet (3 to 6 meters) high. It is widely used as a covering for posts, fences, and porches.

WORLD BOOK illustration by Christabel King

A garden morning-glory has dark heart-shaped leaves and colorful flowers shaped like a funnel.

Garden morning-glories have dark green leaves shaped like a heart. The flowers are shaped like a funnel and are of various shades and mixtures of purple, blue, red, pink, and white. The fragrant flowers open in the morning but close in the sunlight later in the day. The seeds may be soaked in water overnight to soften the seed covering and make sprouting easier. Japanese varieties of morning-glories have flowers 7 inches (18 centimeters) in diameter. Their flowers are mixtures of purple, rose, and violet. The morning-glory is the flower for September. Daniel F. Austin

Scientific classification. Morning-glories belong to the morning-glory family, Convolvulaceae. Common garden morning-glories include *Ipomoea purpurea, I. nil,* and *I. tricolor.*

Rabat, Morocco's capital, lies on the Atlantic Ocean. The wall was originally built along the coast to protect Rabat from enemy attack by sea.

Morocco

Morocco, *muh RAHK oh,* is a country in the northwestern corner of Africa. It is bordered by the Mediterranean Sea on the north and the Atlantic Ocean on the west. The Strait of Gibraltar, which connects the Mediterranean and the Atlantic, separates Morocco from Spain by only about 8 miles (13 kilometers). Fertile plains lie along Morocco's coasts, and forested mountains stretch across the middle of the country from southwest to northeast. Beyond the mountains lies a sun-baked desert, the Sahara. Rabat is Morocco's capital, and Casablanca is the largest city.

Nearly all Moroccans are of mixed Arab and Berber descent. But the people make up two distinct ethnic groups—Arab and Berber—depending mainly on whether they speak Arabic or Berber. Almost all Moroccans are Muslims. Farming is the chief occupation. France and Spain controlled Morocco from the early 1900's until it won independence in 1956.

Government

National government. Morocco is a constitutional monarchy headed by a king. Its Constitution gives the king broad powers. For example, he commands the armed forces, may issue orders that have the force of law, and controls the major agencies of the government.

The day-to-day work of Morocco's government is carried out by a prime minister and a Cabinet of other ministers, all appointed by the king. Morocco has a two-house legislature. Members of the Chamber of Representatives are elected by the people. Members of the Chamber of Councillors are chosen by representatives of local governments, professional organizations, and other groups. Members of both chambers serve five-year terms. All citizens who are 20 years of age or older may vote.

Local government. Morocco is divided into seven provinces. A governor appointed by the king heads each province. The provinces are further divided into

A busy marketplace occupies the heart of Moroccan cities. Many city dwellers wear Western-style clothing, though women who follow Islamic tradition still cover their face with a veil.

prefectures. The national government controls all local governments.

Politics. The Union Constitutionnelle (Constitutional Union), the Mouvement Populaire, and the Rassemblement National des Indépendants (National Rally of Independents) are Morocco's largest political parties that have generally supported the king's policies. The most prominent of the opposition parties are the Union Socialiste des Forces Populaires (Socialist Union of Popular Forces), which backs broad socialist reforms, and the Istiqlal, which takes a more conservative approach to domestic issues. Other parties include the Mouvement National Populaire (National Popular Movement) and a small Communist group headed by the Parti du Renouveau et du Progrès (Party of Renewal and Progress).

Courts. Morocco's highest court is the Supreme Court. Lower courts include appeals courts, regional courts, and *sadad* (conciliation or peace) courts.

Armed forces. Morocco's army, navy, and air force have about 149,000 members. Men may be drafted for $1\frac{1}{2}$ years of service after they reach the age of 18.

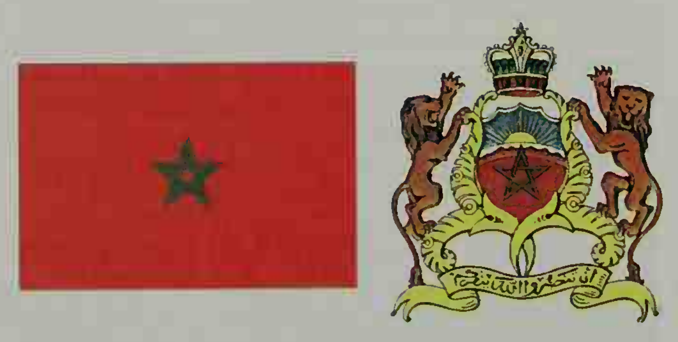
People

Ancestry. Almost all Moroccans are of mixed Arab and Berber ancestry. Berbers lived in what is now Morocco as long as 3,000 years ago. Arabs began to move into the area during the 600's. Over the years, the two groups intermarried so extensively that today there are few Moroccans of unmixed Arab or Berber ancestry. People are identified as Arabs or Berbers chiefly by their main language, Arabic or Berber. According to Morocco's government, Arabs form nearly 65 percent of the population, and Berbers make up the rest.

Languages. Arabic is the official language of Morocco. It is spoken not only by Arabs but also by many Berbers in addition to their own language. A large number of Arabs and Berbers also speak French or Spanish.

Religion. Islam is Morocco's official religion. About 98 percent of the people are Muslims, and Islamic teachings regulate family and community life. Morocco also has some Christians and Jews.

Way of life. The traditional Moroccan household consists of two parents, their unmarried children, their married sons, and those sons' wives and children. When the father dies, each married son begins his own household. In crowded urban areas, many households split up before the father's death because there is not enough room for everyone to live together.



Housing in rural Morocco varies according to climate and available building materials. Many people in the southern part of the country live in houses of dried mud bricks. In other rural areas of Morocco, houses are made of wood and stone.

Many rural houses have only one large room. This room serves as kitchen, living room, sleeping quarters, and barn. People gather at a weekly outdoor market called a *suq* to buy and sell goods and chat with neighbors. In desert regions, a small number of people lead a nomadic life and live in tents.

Many urban Moroccans live in small attached houses. Wealthier people live in spacious houses or modern apartment buildings. Sprawling slums called *bidonvilles* (tin can towns) border the large cities. The name *bidonville* comes from the flattened tin cans, or *bidons,* used to build many of the slum shacks. Severe overcrowding exists in the *medinas* of Morocco's large cities. The medinas are the original city settlements, from which large

Facts in brief

Capital: Rabat.

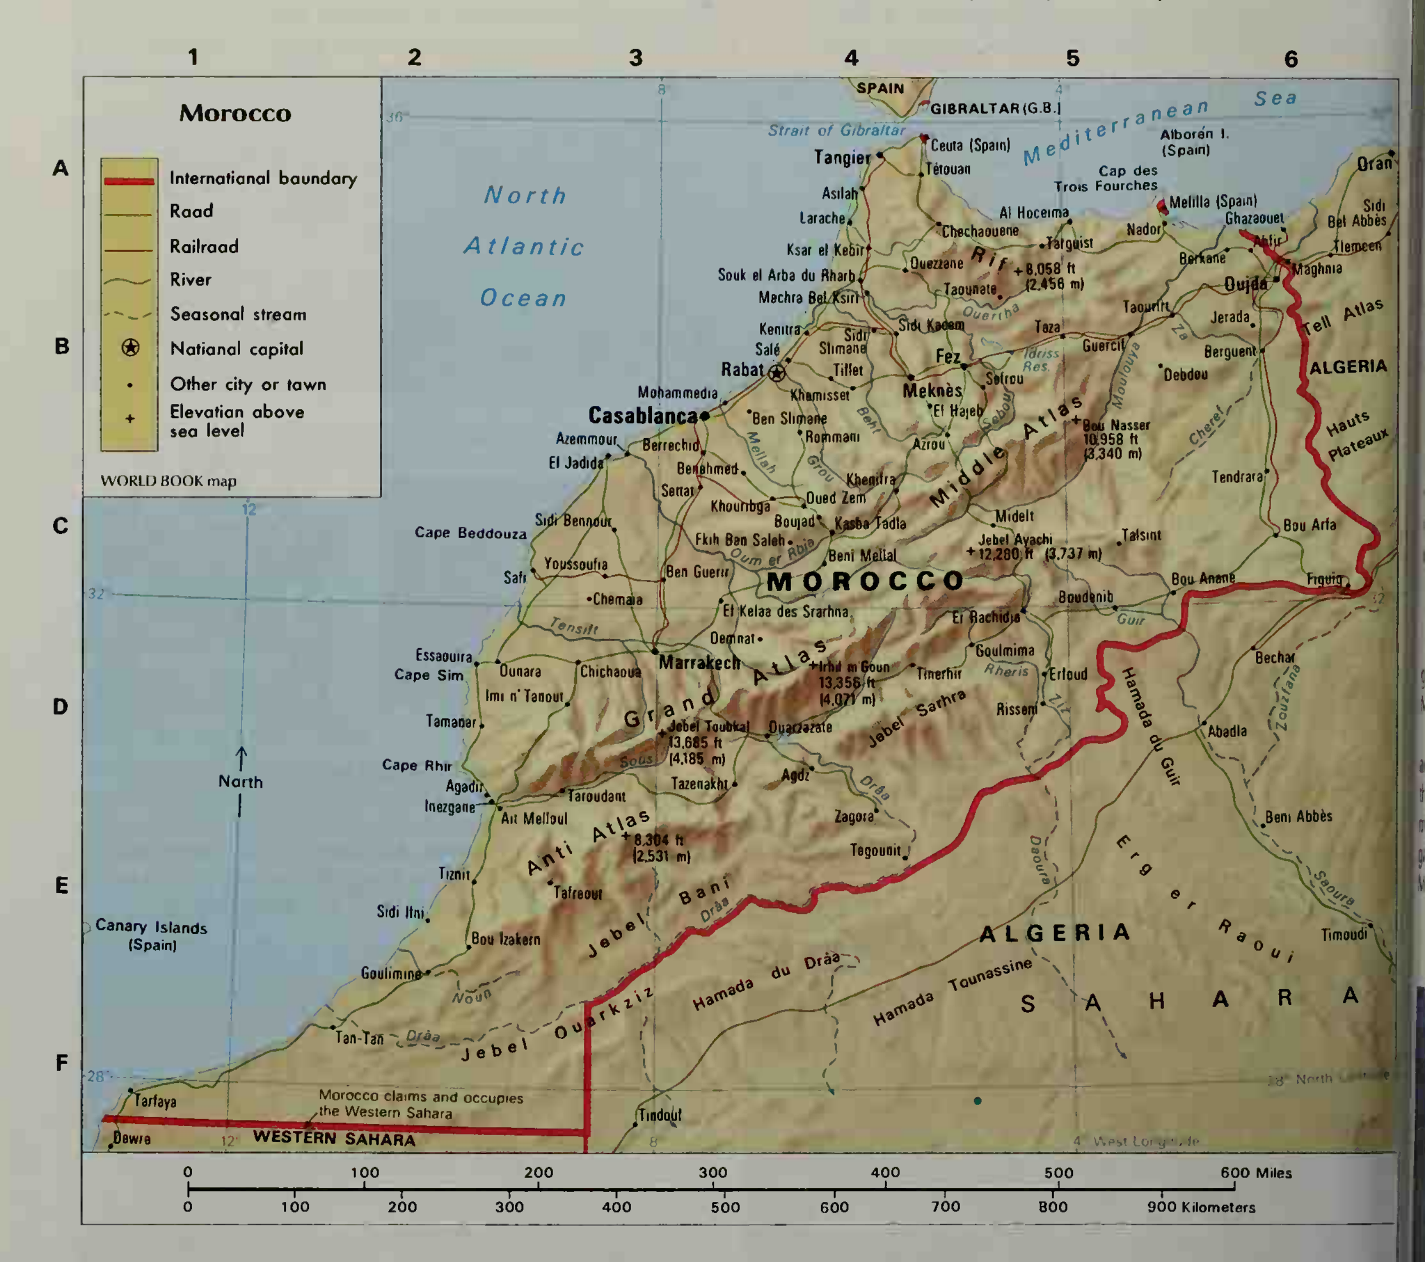
Morocco lies in northwestern Africa. It borders Algeria, Western Sahara, the Atlantic Ocean, and the Mediterranean Sea.



metropolitan areas have grown.

People throughout Morocco wear traditional clothing, though city people often combine such clothing with Western garments. Outdoors, men wear a *jellaba,* a loose-fitting hooded robe with long, full sleeves. A *burnoose* is a similar but heavier garment worn chiefly by rural men. Most men wear a turban or a brimless cap. One type of cap, called a *fez,* is named for the Moroccan city of Fez. This red, flat-topped cap is now usually worn only for formal occasions.

Like men, women wear a jellaba as an outer garment. At home and at social affairs, they wear a long, beautiful robe called a *caftan.* Some older women and some rural women follow Islamic tradition and cover their face with a veil.

Food and drink. Foods made of barley and wheat form the basis of most Moroccans' diet. The national dish is *couscous.* It consists of steamed wheat served with vegetables, fish or meat, and a souplike sauce. Moroccans like pastries made with honey and almonds. The national drink is mint tea.

Recreation. Popular spectator sports in Morocco in-

clude soccer, basketball, and track and field events. Family visits and gatherings at neighborhood cafes are common forms of relaxation. The people also enjoy many local and religious festivals throughout the year.

Education. Morocco provides free elementary and high school education. Classes are taught in Arabic and French. Children are required to attend six years of school, but not all do so. Attendance is especially low in rural areas, which have a lack of teachers and schools. In addition, many rural boys stay at home to help their families farm the land. Moreover, many parents place less value on education for girls than for boys. For the country's literacy rate, see **Literacy** (table: Literacy rates).

Morocco has five state *secular* (nonreligious) universities, the largest of which is Muhammad V University in Rabat. A private university, al-Akhawayn, is in Ifrane, near Azrou, and the Islamic university of al-Qarawiyin is in Fez. Morocco also has 25 technical schools and institutes of higher education.

The arts. Moroccans have long been known for their fine leather goods, rugs, pottery, and metalware. Many Moroccan arts reflect Spanish and French influences as well as Arabic and Berber traditions. For example, traditional Moroccan folk music and folk dances are often combined with the styles of the Andalusian region of southern Spain. French influences can be seen in painting, sculpture, and drama. Modern Moroccan authors, whether writing in Arabic or French, have often dealt with problems of cultural identity and have protested continuing French influences in Morocco.

The land and climate

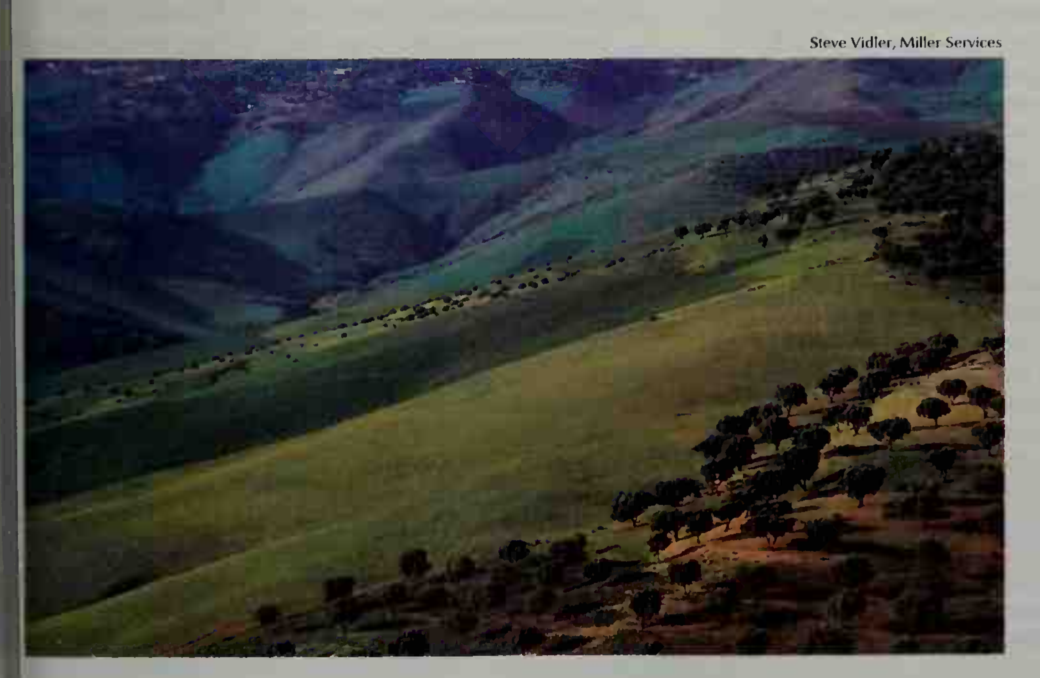
Land regions. Morocco has three major land regions. They are (1) the Coastal Lowlands, (2) the Atlas Mountain Chain, and (3) the Sahara.

The Coastal Lowlands border the Mediterranean Sea and the Atlantic Ocean. The land gradually rises from the Atlantic coast and forms a plateau that extends to the mountains. Rich farmland in the Coastal Lowlands is irrigated by water from the region's many shallow rivers. Most of Morocco's crops are grown there.

The Atlas Mountain Chain crosses the middle of Morocco from southwest to northeast. The chain has three distinct ranges: (1) the Anti Atlas in the southwest; (2) the Grand Atlas, also called Haut Atlas, in the central area; and (3) the Middle Atlas, or Moyen Atlas, in the northeast. The Rif, a group of mountains in the far north, are sometimes included in the Atlas chain.

The Sahara lies east and south of the Atlas Mountains. It is a barren region of sand dunes, rocks, stones, and scattered oases.

Climate. Most of Morocco has two seasons, rainy and dry. The rainy season generally lasts from October or November to April or May. Nearly all the rainfall occurs in this period. Annual rainfall averages 9 inches (229 millimeters) in Marrakech and 21 inches (533 millimeters) in Rabat. Droughts sometimes occur in the dry season, from May or June to September or October. January temperatures average 66 °F (19 °C) in Marrakech and 63 °F (19 °C) in Rabat. June temperatures average 91 °F (33 °C) in Marrakech and 77 °F (25 °C) in Rabat.



Economy

Morocco has a developing economy based mainly on agriculture and mining. The government controls the mining industry, most transportation and communication services, and some manufacturing industries. However, most farms and businesses are privately owned.

Agriculture and fishing employ about 40 percent of all workers in Morocco. The chief crops include wheat, barley, corn, sugar beets, citrus fruits, potatoes, tomatoes, olives, and beans. More than a third of Morocco's farmland is owned by only 3 percent of the nation's farmers. Their large farms produce about 85 percent of all the crops. Most farmers own fewer than 10 acres (4 hectares). The chief livestock are sheep, goats, and dairy cattle. Morocco is one of Africa's leading fishing countries. Sardines, mackerel, tuna, and anchovies are caught off the coasts. Much of the catch is canned for export or processed into either fertilizers or animal feed.

Service industries employ more than 30 percent of Morocco's workers. Tourism is a major service industry. Nearly 2 million tourists, most of them from western Europe, visit Morocco each year. Many service industries

An industrial plant in Safi processes phosphate rock into chemicals called *phosphates.* Morocco leads the world in the export of phosphate rock and is a top producer of phosphates.

workers are employed by hotels, restaurants, and resorts. The government and institutions that provide community services hire many other service workers. Service industries employees also include people in trade, transportation, and communication.

Manufacturing provides jobs for about 15 percent of all Moroccan workers. Most manufactures are produced for local use. They include processed foods; textiles; leather goods; cement; chemicals; paper; and metal, rubber, and plastic products. Fertilizers and petroleum products are produced chiefly for export. Casablanca is the main industrial center.

Mining employs less than 2 percent of Morocco's labor force but is highly important to the economy. Morocco is the world's largest exporter of *phosphate rock,* which is used to produce fertilizers and other chemicals. Morocco has about two-thirds of the world's known reserves of phosphate rock. Other mineral products include coal, copper, iron ore, lead, natural gas, and zinc.

Energy sources. About three-quarters of Morocco's energy needs are supplied by imports, mostly of oil. The rest of the nation's energy requirements comes from its own coal, natural gas, and hydroelectric resources.

Trade. Phosphate rock and phosphate products account for about half of Morocco's export income. Other exports include fruits, fish, vegetables, clothing, and such handicrafts as leather goods and rugs. The chief imports are oil, industrial equipment, and food and other consumer goods. The nation's key trading partners include France, Spain, Germany, and Italy.

Transportation and communication. Highways and government-owned railroads link all major Moroccan cities with one another and with key agricultural and mining areas. Only about 5 percent of the people own a car, but private and government-operated bus service reaches nearly all parts of the country. Most of Morocco's trade is handled at Casablanca. Tangier is the main passenger port. The government-controlled Royal Air Maroc provides international airline service.

About 10 privately owned daily newspapers, printed in both Arabic and French, are published in Rabat and Casablanca. The government controls radio and TV broadcasts. TV programs are broadcast in Arabic and French, and radio programs in Arabic, French, Berber, Spanish, and English.

History

Farming communities existed in what is now Morocco at least 8,000 years ago. By 1000 B.C., Berbers had migrated to the region. They may have come from Europe, southwestern Asia, or northeastern Africa. From about A.D. 40 to the 600's, the region was ruled, in turn, by the Romans, Vandals, and Byzantines.

Arab conquest. During the 680's, Arabs from the Arabian Peninsula invaded Morocco. Many Berbers adopted the religion of the Arabs, Islam. But they resented the Arabs' political control.

In the late 700's, an Arab leader named Idris ibn Abdallah united the region's Berbers and Arabs under his rule, thereby creating the first Moroccan state. He also founded the Idrisid *dynasty* (series of rulers from the same family), which governed Morocco for almost 200 years. The country's rulers came to be called *sultans.* Fez, the Idrisid capital, developed into a major religious and cultural center of the Islamic world.

From about 1050 through the mid-1400's, Morocco was ruled by three Islamic Berber dynasties. At various times, the Berber empires covered much of northern Africa and extended into the Christian lands of Spain and Portugal. But by the 1200's, the Christians had begun to drive the Muslims from Portugal and Spain.

Corsairs and sharifs. The last Muslims were driven from Spain in the 1500's. Meanwhile, Spain and Portugal had begun to seize territory on Morocco's coasts. The rivalry between Muslims and Christians contributed to widespread naval warfare in the western Mediterranean. Private warships commanded by Muslim *corsairs* (sea raiders) attacked ships and coastal towns of Christian nations. In addition, Muslims and Christians attacked one another's ships and ports. The port of Salé was a major base for Moroccan corsairs.

Arab tribes and families of *sharifs* helped lead Moroccans' opposition to the Christian seizures of their territory. Sharifs were descendants of Muhammad, the prophet of Islam. In the mid-1500's, a sharifian family named the Saadians gained control of Morocco and founded a dynasty that ruled until the mid-1600's. Since then, the Alawis, another sharifian family, have been Morocco's reigning dynasty.

French and Spanish control. Through treaties and military victories, France and Spain established control over the economic and political affairs of Morocco by the early 1900's. Sultan Hassan I, who ruled from 1873 to 1894, had tried to modernize Morocco's government and its army. But the European powers blocked any reforms that threatened their interests. Hassan was succeeded by his son Abd al-Aziz.

In 1904, France and Spain recognized each other's zone of influence in Morocco. Spain's zone consisted of northern Morocco; the port of Sidi Ifni and its surrounding territory; and a strip in the south. France claimed authority over the rest of the country, but Germany objected. The major powers met in 1906 in Algeciras, Spain, to discuss France's growing power in Morocco. The conference upheld Morocco's independence, though France and Spain kept their special privileges.

France sent troops to Morocco in 1907 because of

mounting hostility against the growing European influence in the country. The presence of French forces further enraged the Moroccans. Abd al-Aziz was overthrown by his brother Abd al-Hafidh in 1908. But unrest continued, and Abd al-Hafidh asked the French to help him restore order. In 1912, Abd al-Hafidh signed the Treaty of Fez with France. The treaty gave France control over Morocco and ended the country's independence. Spain was granted control of its zone of Morocco by France. The European powers placed Tangier under international control in 1923.

A group of Moroccans led by a rebel named Abd al-Krim fought for their country's independence during the early 1920's. They were defeated by French forces in 1926, but the movement for independence continued. In 1934, a group of Moroccans drew up the Plan of Reforms. It called for a reinterpretation of the Treaty of Fez that would guarantee Moroccans' political rights. France rejected the plan. Following widespread demonstrations in 1937, France arrested or exiled leaders of the independence movement.

Independence. Morocco was the scene of fighting between Allied and Axis forces during World War II (1939-1945). In 1943, U.S. President Franklin D. Roosevelt and British Prime Minister Winston Churchill met in Casablanca to discuss war plans. That same year, the Istiqlal (Independence) Party was formed to work for Morocco's freedom.

Sultan Muhammad V supported the Istiqlal Party. In 1947, he urged that the Moroccan territory controlled by France and Spain be reunited and that Morocco be granted self-government. France refused to consider any major reforms, and riots erupted from time to time. In 1953, the French sent Muhammad into exile and imprisoned some Istiqlal leaders. The sultan's exile angered many Moroccans, and acts of violence became common. New Istiqlal leaders formed the National Liberation Army, which openly fought French troops. To restore order, the French brought Muhammad back in late 1955 and promised to grant Morocco its freedom.

On March 2, 1956, Morocco became independent of France. In April, Spain gave up nearly all its claims in northern Morocco. The international city of Tangier again became part of Morocco in October.

Constitutional monarchy. Muhammad's great popularity enabled him to organize the government as he wished. In 1957, he changed his title from sultan to king as part of his plan to make Morocco a constitutional monarchy. But rivalries among political parties endangered the country's stability. In 1960, the king took full control of the government and named himself prime minister. He died in 1961. Muhammad's son, Hassan II, then became king and prime minister. In 1962, Morocco adopted its first Constitution. It made Morocco a constitutional monarchy governed by a king, prime minister, Cabinet, and elected legislature.

Unemployment and high inflation were among the problems facing Morocco in the early 1960's. Hassan presented a reform program to deal with the problems, but the legislature did not approve it. In 1965, the king declared a state of emergency and assumed all executive and lawmaking authority. The state of emergency lasted until 1970, when the people approved a new Constitution and elected a new legislature.

Hassan again took control of Morocco's government in 1972, after military officers had tried for the second time to assassinate him. Moroccans approved a third Constitution that same year, but a new legislature was not elected until 1977. Morocco's present Constitution came into effect as a result of changes made in 1992.

Dispute over Western Sahara. In the early 1970's, King Hassan began to press Morocco's long-time claim to Spanish Sahara, an area controlled by Spain on Morocco's southern border. Mauritania also wanted parts of the area. However, the Polisario Front, an organization in Spanish Sahara, demanded independence. In 1976, Spain gave up the area to Morocco and Mauritania. Morocco claimed the northern part, and Mauritania the southern. The area is now called Western Sahara.

The Polisario Front continued to demand independence for Western Sahara. Fighting broke out between the Front and troops from Morocco and Mauritania. Algeria and Libya provided military aid to the Front. In 1979, Mauritania gave up its claim to Western Sahara. Morocco then claimed the entire area. Fighting between Morocco and the Polisario Front continued.

A cease-fire was declared in September 1991. The cease-fire plan also called for a *referendum* (direct vote) to determine whether Western Sahara would become independent or a part of Morocco. Disagreements between Morocco and the Front over voter eligibility repeatedly delayed the referendum.

Recent developments. King Hassan died in 1999. His son Sidi Muhammad succeeded him as King Muhammad VI. Kenneth J. Perkins

Where are most of Morocco's crops grown?

Moroni (pop. 26,000) is the capital and largest city of Comoros. Moroni lies on the west coast of Grande Comoro island. For location, see **Comoros** (map).

Moroni is the nation's center of government, trade, and tourism. It is home of the nation's main *mosque* (Muslim house of worship), chief *lycée* (secondary school), and sole international airport. The architecture in Moroni shows an Arab influence. Arabs ruled the Comoros Islands from the 1400's until the 1800's, when France gained control. Moroni became the capital of Comoros in 1962, after the nation declared its independence from France in 1961 (see **Comoros** [History]).

Leroy Vail

Morpheus, *MAWR fee uhs* or *MAWR fyoos,* was a god of dreams in Greek mythology. He was one of the sons of Hypnos, the god of sleep. He took human form and appeared to people in their sleep. To be "in the arms of Morpheus" means to be asleep, and the drug morphine is named after him. Justin M. Glenn

Morphine is a drug used to relieve severe pain and to treat several other medical problems. Some people use morphine because it makes them feel happier. In the United States, federal laws prohibit the use of this drug except when prescribed by a physician.

People who use morphine regularly may in time become addicted to it. If they stop their usual dose, they will feel ill for several days unless they take medicine for this *withdrawal sickness.* Withdrawal sickness may include abdominal cramps, back pains, chills, diarrhea, nausea, vomiting, and weakness.

Morphine makes severe pain bearable and moderate pain disappear. The drug also stops coughing and diarrhea, checks bleeding, and may help bring sleep. Doctors give patients morphine only if other medicines fail. Besides being addictive, morphine interferes with breathing and heart action and may cause vomiting.

Small doses of morphine leave the mind fairly clear. Larger doses cloud the mind and make the user feel extremely lazy. Most morphine users feel little hunger, anger, sadness, or worry, and their sex drive is greatly reduced. Most people with mental or social problems feel happy after using morphine, even though their problems have not really been solved.

Some morphine addicts can give up the drug fairly easily with medical help. But an addict with many problems—mental, physical, or social—may find morphine hard to give up. Personal counseling, controlled living situations, and such medicines as methadone may help addicts solve their problems and stop taking morphine (see **Drug abuse; Methadone**).

Morphine is made from opium, and heroin is manufactured from morphine. These three drugs have similar effects. However, heroin is the strongest and opium is the least powerful. See **Heroin; Opium.** Donald J. Wolk

Morphology, *mawr FAHL uh jee,* is the branch of science that deals with the structure of animals, plants, and nonliving matter. Morphology most often involves the study of living things. It includes such areas as *cytology,* the study of cell structure; *histology,* the study of tissue structure; and *anatomy,* the study of the structure of whole organisms. In geology, morphology is the study of the external form of rocks. Lawrence C. Wit

Morrill, Justin Smith (1810-1898), was a United States political leader. He represented Vermont in the U.S. House of Representatives from 1855 to 1867, and in the U.S. Senate from 1867 to 1898. He proposed the Morrill Act of 1862, which established land-grant colleges and universities (see **Land-grant university**). He introduced the Morrill Tariff Act of 1861. He also helped found the Republican Party and helped pass legislation that established the present Library of Congress. Morrill was born in Strafford, Vt. Dan L. Flores

Morrill acts. See **Land-grant university.**

Morris, Desmond (1928-), is a British zoologist. He has written or coauthored more than a dozen books that have increased popular interest in the behavior of animals and human beings. Morris has also helped make films and television programs that explore the social behavior of animals.

Morris' best-known books are *The Naked Ape* (1967) and *The Human Zoo* (1969). These books, written from the viewpoint of a zoologist, discuss the basic elements of animal behavior in human beings. Morris examines the ways that humans behave socially in modern-day urban society. *The Naked Ape* became widely popular, but some scientists criticized it because they thought its entertainment value outweighed its scientific value. Morris also wrote *The Biology of Art* (1962) and *The Mammals: A Guide to the Living Species* (1965). With his wife, Ramona Morris, he wrote *Men and Snakes* (1965), *Men and Apes* (1966), and *Men and Pandas* (1966). Desmond John Morris was born in Purton, England, near Swindon. G. J. Kenagy

Morris, Esther Hobart (1814-1902), led the fight for women's suffrage in Wyoming. Through her efforts, the territory of Wyoming passed a women's suffrage law in 1869 that became a model for later suffrage laws. When Wyoming became a state in 1890, it was the first state to permit women to vote.

Born Esther McQuigg in Tioga County, New York, she settled in the Wyoming territory in 1868. She became the first woman justice of the peace in the United States in 1870. A statue of Morris represents Wyoming in Statuary Hall in the United States Capitol in Washington, D.C. Louis Filler

Morris, Gouverneur, *GUHV uhr NEER* (1752-1816), was an American statesman and diplomat. He headed the committee that wrote the final draft of the Constitution of the United States. Much of the credit for the wording in the Constitution belongs to him.

Morris was suspected of sympathies for Great Britain at the outbreak of the Revolutionary War in America in 1775. But he soon proved himself to be one of the most active American patriots. He served as a leading member of the New York constitutional convention in 1776. He was a member of the Second Continental Congress from 1778 to 1779. The brilliant and energetic Morris headed several committees of Congress and acted as draftsman of important documents. He was one of General George Washington's most able supporters in Congress during the Revolutionary War. Morris attracted the attention of Robert Morris, financial agent of Congress, and served as assistant superintendent of finance from 1781 to 1785.

Morris was elected a Pennsylvania delegate to the Constitutional Convention of 1787. He spoke 173 times—more often than any other delegate—and favored a strong, centralized government controlled by the

wealthy. In 1789, Morris went to Paris as a financial agent. From 1792 to 1794, he was minister to France. From 1800 to 1803, he was a U.S. senator from New York. Morris was also a key figure in promoting the construction of the Erie Canal. He was born in Morrisania (now part of New York City). Richard D. Brown

Morris, Lewis (1726-1798), was a signer of the Declaration of Independence from New York. He served in the Continental Congress from 1775 to 1777, where he worked on committees supervising supplies of ammunition and military stores. Morris served in the New York state legislature from 1777 to 1790. He was a brigadier general of the New York militia during the Revolutionary War in America (1775-1783). Morris was born in Morrisania (now part of New York City) and was a half brother of Gouverneur Morris (see **Morris, Gouverneur**).

Gary D. Hermalyn

Morris, Robert (1734-1806), a Pennsylvania merchant and banker, was one of six people who signed both the Declaration of Independence and the Constitution of the United States. Morris became one of the wealthiest people in the American Colonies. He raised great amounts of money to support the Continental Army during the Revolutionary War in America (1775-1783). Because of this, he was known as "the financier of the American Revolution."

Morris was born in or near Liverpool, England. He came to the American Colonies at the age of 13. Morris' energy and intelligence helped him become an important member of a Philadelphia shipping and banking firm at the age of 20.

From 1775 to 1778, Morris served in the Second Continental Congress. This congress adopted the Declaration of Independence in 1776. He was superintendent of finance of the United States from 1781 to 1784. The treasury of the new country had all but collapsed because of the Revolutionary War in America. Morris improved the unsettled financial condition by establishing the Bank of North America, which opened in 1782. Through Morris' efforts, the Continental Army had supplies and money that helped it win a decisive victory in the Battle of Yorktown. This victory ensured the success of the revolution.

After the war, Morris expanded his fortune through commercial and real estate undertakings. He attended almost every session of the Constitutional Convention of 1787 but played a minor role. Morris represented Pennsylvania as a United States senator from 1789 to 1795. By the time he left the Senate, Morris had invested heavily in unsettled land throughout the nation. By the late 1790's, however, his credit had collapsed. Morris was sent to debtor's prison in 1798. He was released in 1801, and spent the last years of his life living in near poverty.

Richard D. Brown

Morris, William (1834-1896), was an English poet, artist, and socialist reformer. He fell in love with medieval culture and acquired a deep knowledge of English Gothic architecture. Morris wanted to replace the mass-produced objects of his time with the beauty and individuality he saw in medieval art.

Morris retold many myths and epics. His romantic narrative *The Life and Death of Jason* (1867) recounts the adventures of the Greek mythological hero. *The Earthly Paradise* (1868-1870) is a poem modeled on Geoffrey Chaucer's *The Canterbury Tales.*

Morris became interested in interior design as an art form. In 1861, he founded a company that produced furniture, wallpaper, stained glass, tapestries, and other decorative articles for the home. His experiments in furniture led to the design of the popular Morris chair.

Morris created his own publishing company, the Kelmscott Press, in 1890. The press printed artistic editions of distinguished literary works. It stimulated artistic book design and printing in other countries. See **Book** (picture: A beautiful book; The 1800's).

In his later years, Morris became a lecturer and propagandist for socialist solutions to problems created by the Industrial Revolution. He wrote the romances *A Dream of John Ball* (1888) and *News from Nowhere* (1891), both landmarks of the English socialist movement. Morris was born in Walthamstow, near London.

Morrison, Toni (1931-), a black American novelist, won the 1993 Nobel Prize for literature. The Nobel Committee cited Morrison for novels that give "life to an essential aspect of American reality." The committee also noted that she "delves into the language itself, a language she wants to liberate from the fetters of race. And she addresses us with the luster of poetry."

Morrison won the 1988 Pulitzer Prize for fiction for *Beloved* (1987). The novel tells the story of a former slave tragically haunted by memories of her life in slavery and the baby she killed to save the child from that fate. *Beloved* demonstrates Morrison's lyrical style, vivid characterizations, and ability to persuade readers to accept the unusual as real.

Morrison's first two novels, *The Bluest Eye* (1970) and *Sula* (1973), focus on the lives of black women and girls. In *Song of Solomon* (1977), a man learns that he must reject his father's self-centered materialism and discover strength in love for friends. In *Tar Baby* (1981), a black man and woman fail to sustain their relationship because of class differences. *Jazz* (1992) is set in Harlem during the 1920's. It takes its themes from the power of jazz music.

Morrison was born in Lorain, Ohio. Her real name was Chloe Anthony Wofford. She married Harold Morrison in 1958. They were divorced in 1964. In addition to her novels, Morrison has published a collection of essays, *Playing in the Dark* (1992). Nellie Y. McKay

Morse, Samuel Finley Breese (1791-1872), was a famous American inventor and painter. He received the patent for the first successful electric telegraph in the United States. He also invented the Morse code, used for many years to send telegraphic messages (see **Morse code**). Morse helped found the National Academy of Design and served as its first president.

Early years. Morse was born on April 27, 1791, in Charlestown, Mass. His family was devoutly Calvinist, and its conservative religious beliefs influenced Morse throughout his life.

Morse attended Yale University. While there, he studied chemistry with Benjamin Silliman and natural philosophy with Benjamin Day. Both men also lectured on the new science of electricity. From Silliman, Morse learned

about batteries and constructed several of his own. However, Morse was an indifferent student. His real passion was art.

Brown Bros.
Samuel F. B. Morse

Morse graduated from Yale in 1810. The following year, he obtained reluctant permission from his parents to study art abroad. He studied in London with two American-born masters—Washington Allston and Benjamin West. He also studied at the Royal Academy of Arts, where he learned the "Grand Style" of art, which featured themes from history and mythology. In 1813, his first and only sculpture, a figure of the dying Hercules, won critical acclaim and a gold medal in the Adelphi Society of Arts competition. In 1815, having spent all the funds his parents could spare, Morse regretfully returned home.

Morse as artist. Back in the United States, Morse was unable to secure an income from the historical painting he regarded as his true calling. In order to earn money, he began painting portraits of members of fashionable society. Although he considered this type of painting to be inferior to true art, he became successful at it. Among his famous subjects were President James Monroe, the poet William Cullen Bryant, and the inventor Eli Whitney. Morse's portrait of the French soldier and statesman Marquis de Lafayette became the best known of all his paintings.

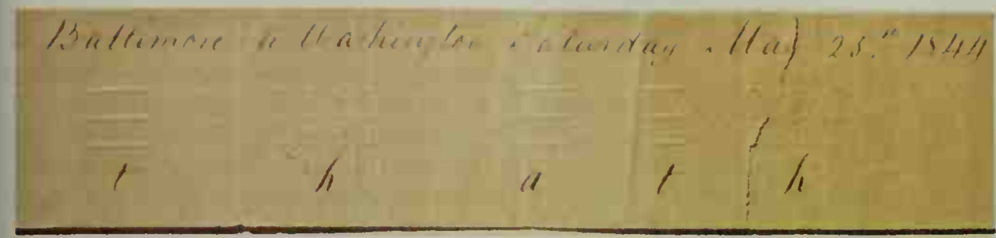
Despite his success as a portrait painter, Morse continued to struggle financially. In 1822, he finished work on a painting that depicted the House of Representatives in session with recognizable portraits of more than 80 members. He planned to charge admission for viewing it, but the public was largely indifferent. Several years later, Morse made another attempt with an elaborate painting of the interior of the Louvre museum in Paris. But this scheme met with the same disappointing result.

In 1826, Morse and 30 other American artists founded the National Academy of Design. Morse was chosen president, an office he held continuously until 1845.

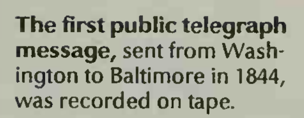
From 1829 to 1832, Morse traveled in Europe, perfecting his artistic technique. In 1832, he was appointed professor of painting and sculpture at the University of the City of New York (now New York University). He later became professor of the literature of the arts of design there. About this time, Morse began his involvement in the *nativist movement.* This movement regarded immigration and Roman Catholicism as threats against an authentic American republic. Morse wrote a number of passionate articles supporting these positions. In 1836, he ran for mayor of New York City on the Native American ticket but lost the election.

In the mid-1830's, Morse was denied an important commission he had hoped to obtain to paint historical murals for the Rotunda of the Capitol in Washington, D.C. Frustrated once again in his dream of devoting himself to art, Morse shifted his attention to the telegraph. After 1837, he did not paint again.

Morse as inventor. Morse diligently pursued a number of schemes in an effort to acquire an independent livelihood that would enable him to support himself as a serious artist. Among these projects were the invention of a pump for fire engines and a marble-cutting machine to reproduce statues mechanically. The most successful of these efforts, however, was the telegraph.



Morse had been interested in electricity since his student days at Yale. In 1827, for example, he attended a series of lectures on electricity given at Columbia University by the American chemist James Freeman Dana. Then, during his return voyage from Europe aboard the ship *Sully* in 1832, Morse discussed with several other passengers the possibility of transmitting "intelligence" at a distance by electricity. He theorized in his diary that transmission could be based on a single circuit using underground wires. He also improvised possible codes.



Work on the telegraph went slowly. Too poor to buy insulated wires on reels, he bought wire in pieces and soldered the pieces together. He wrapped the wire—bit by bit—with cotton thread. He built his instruments from old clockworks and art equipment.

Morse was scientifically inexperienced and baffled by a variety of technical problems. In early 1836, he began to work jointly on the telegraph with Leonard Gale, who taught chemistry at the University of the City of New York. Gale alerted Morse to the work of Joseph Henry, a

Oil painting on canvas (1825); Art Commission of the City of New York (WORLD BOOK photo by E. E. Smith)

Samuel F. B. Morse first won recognition as a painter. His portrait *Marquis de Lafayette, above,* shows his artistic skill.

The first public telegraph message, sent from Washington to Baltimore in 1844, was recorded on tape.

Smithsonian Institution

Morse built a port rule to operate the key of his telegraph. The key established a circuit that allowed current to pass to the receiver.

Smithsonian Institution

physicist at the College of New Jersey (now Princeton University), who had built a crude electromagnetic acoustic device several years earlier. By the end of 1837, Morse and Gale had built an electromagnetic telegraph based on Henry's work. This device could send messages 10 miles (16 kilometers) on wire strung around Morse's workroom.

Another key collaborator on the project was Alfred Vail, a skilled mechanic with access to a machine shop. He had approached Morse and offered him funds and assistance. Morse promptly made him a partner.

In 1837, Congress sought proposals for a telegraph system to connect the financial market of New York City with the cotton market of New Orleans. Only Morse proposed an electric system, but Congress would not advance funds for a small experimental line. In 1840, Morse was granted a U.S. patent for his telegraph. In its 1841-42 session, Congress once more failed to act on Morse's telegraph bill.

Finally, in 1842, his work received a favorable report from the Committee on Commerce. In 1843, Congress granted him $30,000 to build a test line between Baltimore and Washington, D.C. On May 24, 1844, Morse demonstrated the line by tapping out the famous message, "What hath God wrought!" Morse earned national praise for his device, but the government did not buy his patents or sponsor a national telegraph.

The next decade saw hard-fought legal and economic battles between Morse and some of his original associates. One fight involved his refusal to acknowledge Joseph Henry's key theoretical contributions to the telegraph. In 1859, discouraged from years of fighting, Morse and his partners sold their patent rights.

Later life. After gaining recognition at home and abroad for his part in developing the telegraph, Morse focused his attention on politics. He continued his support of the nativist movement. He was also an ardent antiabolitionist, believing that slavery had been ordained by the Bible. He was active in the Democratic Party. He ran for Congress in 1854 but lost the election.

By the 1860's, Morse had finally achieved a degree of financial security. He became a vice president of the new Metropolitan Museum of Art and a trustee of Vassar College. He also made donations to Yale and to various religious and moral societies. In 1871, the telegraph industry honored him with a statue in Central Park in New York City. Carolyn Marvin

Morse, Wayne Lyman (1900-1974), served as United States senator from Oregon, first as a Republican, then as a Democrat. He was elected in 1944 and in 1950 as a Republican. Calling himself an "independent Republican," Morse withdrew from the Republican Party in 1952 and supported the Democratic Party's presidential candidate Adlai E. Stevenson. Morse became a Democrat in 1955 and was reelected to the Senate as a Democrat in 1956 and 1962. He lost bids for reelection in 1968 and 1972. His major interests in the Senate included labor-management relations, Latin-American affairs, and international law. In the 1960's, Morse became one of the most outspoken critics of United States involvement in the Vietnam War.

Morse was born on Oct. 20, 1900, in Madison, Wisconsin. He graduated from the University of Wisconsin in 1923, and earned law degrees at the University of Minnesota and at Columbia University. Morse began teaching law at the University of Oregon in 1929. He served as dean of the university's law school from 1931 through 1944. James I. Lengle

Morse code is a system of sending messages that uses short and long sounds combined in various ways to represent letters, numerals, and other characters. A short sound is called a *dit;* a long sound, a *dah.* Written code uses dots and dashes to represent dits and dahs.

The code is named for the American inventor and painter Samuel F. B. Morse, who patented the telegraph in 1840. In the past, telegraph companies used *American*

WORLD BOOK chart

International Morse Code, *above,* uses short and long sounds, which are written out as dots and dashes.

Morse Code to transmit telegrams by wire. An operator tapped out a message on a *telegraph key,* a switch that opened and closed an electric circuit. A receiving device at the other end of the circuit made clicking sounds and wrote dots and dashes on a paper tape. Today, the telegraph and American Morse Code are rarely used.

The *International Morse Code* was derived from the American Morse Code for use by radio telegraphers. Today, only amateur and maritime radio operators still use this code regularly. Military and commercial operators may also use it when radio signals are too weak for other systems to work. In this code, a dah is three times as long as a dit. Between the sounds that represent a character, there is an interval of silence as long as one dit. Between letters are three such intervals; between words, seven intervals.

Mortality rate. See Birth and death rates.

Mortar is a short-range weapon that is used to reach nearby targets that are protected by hills or other obstacles. A mortar fires a shell on a high arc that enables it to clear obstacles. It has a higher angle of fire, shorter barrel, and lower muzzle *velocity* (speed) than a gun or a howitzer. Mortars are light, can be moved easily, and have great firepower. For example, the 81-millimeter mortar can fire an 11-pound (5-kilogram) shell nearly 3 miles (4.8 kilometers).

A mortar consists of a tube closed at the *breech* (bottom) end, that rests on a base plate. Two adjustable legs support the muzzle end. Soldiers fire the mortar by dropping the ammunition down the muzzle. When the ammunition reaches the bottom, it strikes the firing pin, which explodes the *primer.* Most mortar shells have fins to prevent them from tumbling in the air. Artillery mortars have *bore* diameters of 105 millimeters or larger. Infantry mortars have diameters that are less than 105 millimeters.

Before World War II (1939-1945), armies used heavy, stubby mortars. Large mortars were also used to defend coastlines. But howitzers have largely replaced these heavy mortars in present-day warfare. The lightweight and easily moved infantry mortar became an important weapon during World War II. Frances M. Lussier

Morte Darthur. See Malory, Sir Thomas.

Mortgage is a loan agreement that enables a person to borrow money to purchase a house or other property. The property is used as security for the loan. If the borrower does not repay the loan on time, the lender may take possession of the property. Almost all mortgages involve real estate.

A mortgage actually consists of two legal documents. One document, called a *note,* specifies the amount of the loan, the repayment terms, and other conditions of the agreement. The other document is the mortgage itself, which gives the lender legal claim to the property if the loan is not repaid. The term *mortgage* commonly refers to the entire loan agreement. The lender is called the *mortgagee,* and the borrower is called the *mortgager.*

A person can obtain a mortgage from a bank, insurance company, mortgage company, savings and loan association, or other financial institutions. The interest rate and other terms vary from lender to lender. Most mortgage agreements require the mortgager to repay the loan in monthly installments over a period of 20 years or more. Part of each payment goes toward the unpaid balance of the loan, called the *principal,* and part toward the interest. As the borrower pays off the loan, more of each monthly payment goes toward the principal, and less toward the interest. The mortgager gradually increases the *equity,* which is the value of the property beyond the amount owed on it.

If the borrower misses a number of payments or violates any other condition of the agreement, the lender may *foreclose* the mortgage. Foreclosure is a legal procedure by which the lender takes over the mortgaged property. The lender then may sell the property, keep the amount owed, and give the borrower the rest. More

U.S. Army

81-mm mortars, *above,* are lightweight and easy to move. They have a maximum firing range of about 3 miles (4.8 kilometers).

than one mortgage may be placed on a property. If foreclosure occurs, the holder of the *second mortgage* gets nothing until the claims of the first have been met.

Two United States government agencies, the Federal Housing Administration (FHA) and the Department of Veterans Affairs, guarantee some home mortgage loans against loss to the lender. Loans unprotected by a government agency are called *conventional loans.*

Mortgage loans have traditionally been a popular investment for financial institutions because of the great safety of such loans. During periods of rapidly rising prices, however, lenders may hesitate to tie up their money in mortgages. Interest rates soar during these periods of *inflation,* but most mortgages pay interest at a fixed rate throughout their term. Thus, a lending institution that issues a 25-year mortgage at 8 percent interest may lose an opportunity to lend the money later at 12 percent. Inflation also drives down the purchasing power of money. As a result, the dollars that lenders get back have less buying power than the dollars they lent. Therefore, in periods of inflation, many lending institutions charge an additional fee called *points* for granting a mortgage loan. Each point equals 1 percent of the amount of the loan. The fee is regarded as prepaid interest and must be paid when the mortgage is signed.

To counteract the effects of inflation, lending institutions have developed other types of mortgages. In a *graduated-payment mortgage,* the borrower makes lower monthly payments for the first few years and higher payments later. In a *variable-rate* or *adjustable-rate* mortgage, the interest rate rises and falls in relation to current interest rates. In a *growing-equity mortgage,* monthly payments increase between 3 and 7 percent yearly until the balance is paid. In a *balloon-payment mortgage,* payments are lower for the first few years and then a large single payment repays the remaining balance. Mark J. Riedy

Mortician. See **Embalming** (Modern embalming).

Morton, Jelly Roll (1890-1941), was the first important jazz pianist and the first great jazz composer. His style of traditional jazz merged ragtime and blues with group improvisation. His recordings from 1926 to 1930 with a small band he led called the Red Hot Peppers are considered classics of the recorded jazz repertory. Morton's compositions include such jazz standards as *King Porter Stomp, Grandpa's Spells, The Pearls,* and *Wolverine Blues.*

Morton was born in New Orleans to a French Creole family. His real name was Ferdinand Joseph Lamothe (also spelled Lemott). With changing tastes in jazz styles, Morton faded into obscurity in the early 1930's. In 1938, folklorist Alan Lomax recorded many interviews with Morton for the Library of Congress. Morton recounted his experiences in jazz while demonstrating the music on the piano. The interviews provided an invaluable account of the early days of jazz and renewed Morton's career. Morton made a few more outstanding recordings before his death, including *The Crave* and *Winin' Boy Blues.* Frank Tirro

Morton, John (1724-1777), was a Pennsylvania signer of the Declaration of Independence. He served in the Continental Congress from 1774 to 1777. Although trained as a surveyor, Morton's greatest achievements were in politics and law. He began his political career in 1756 as a member of the Pennsylvania Assembly, where he served for 17 years. He was also one of the colony's four delegates to the Stamp Act Congress in 1765. In 1774, he became an associate judge of the Pennsylvania Supreme Court. Morton was born in Ridley, Pa.

Robert A. Becker

Morton, Julius Sterling (1832-1902), an American political leader and nature lover, established the first United States observance of Arbor Day, a day for planting trees (see **Arbor Day**). Morton was U.S. secretary of agriculture from 1893 to 1897 in President Grover Cleveland's Cabinet. He was secretary of the Nebraska Territory from 1858 to 1861 and also served as acting governor of the territory for several months. He was born in Adams, N.Y., and received degrees from the University of Michigan and Union College. Nebraska placed a statue of Morton in the United States Capitol in 1937.

Edward A. Lukes-Lukaszewski

See also **Nebraska** (Places to visit [Arbor Lodge]).

Morton, Levi Parsons (1824-1920), served as Vice President of the United States from 1889 to 1893 under President Benjamin Harrison. He also was minister to France from 1881 to 1885 and governor of New York in 1895 and 1896. Morton belonged to a conservative group of Republicans called the Stalwarts. His political success started in 1879 when he was elected to the U.S. House of Representatives from New York.

Morton was born in Shoreham, Vt. He entered the banking business during the Civil War (1861-1865) and became a prominent New York City banker. His company, through its London branch, was the financial agent of the U.S. government from 1873 to 1884.

Edward A. Lukes-Lukaszewski

Morton, Oliver Perry (1823-1877), served as governor of Indiana during the Civil War and as a Republican United States senator from 1867 until his death. He was elected lieutenant governor in 1860, and became governor in 1861 when Governor Henry Lane resigned to enter the Senate. As governor, Morton helped raise volunteer troops. He raised money through his own efforts to support troops when the Indiana legislature refused to grant him funds. Morton was born in Wayne County, Indiana. Indiana placed a statue of Morton in the U.S. Capitol in 1900. James E. Sefton

Morton, William Thomas Green (1819-1868), an American dentist, made the first public demonstration of ether in 1846. Crawford W. Long used ether during surgery in 1842, but he did not publish his discovery until 1849 (see **Long, Crawford W.**).

Morton first used ether in a tooth extraction at the suggestion of Charles T. Jackson, a professor of chemistry at Harvard University. He used it again in 1846 in an operation performed by John C. Warren at the Massachusetts General Hospital. This public demonstration marked a turning point in the acceptance of anesthesia by the medical community. The method spread rapidly to Britain, France, and other countries.

In 1850, the French Academy of Science awarded the Montyon prize of 5,000 francs jointly to Jackson and Morton. Both men claimed sole credit for the discovery, and Morton refused to share the prize. A bitter quarrel

and lawsuits followed, and Morton was ruined financially. The U.S. Congress set up a committee to examine the rival claims, but it could not reach a decision. Morton was born in Charlton, Mass. Edwin S. Munson

Mosaic, *moh ZAY ihk,* is an art form in which small pieces of colored glass, stone, or other material are set into mortar. The pieces, called *tesserae* or *tessellae,* fit together to form a picture. Most mosaics decorate ceilings, floors, and interior walls, but some are used for such exterior surfaces as pavements and outside walls. Since the mid-1500's, mosaics have also been used to decorate furniture and objects of personal adornment as well as for architectural ornament.

People in ancient Mesopotamia may have made mosaics as early as the 3000's B.C. However, the widespread use of mosaics began during the 300's B.C. in areas ruled by Greece. The Greeks later taught mosaic design to the Romans, who developed their own style of the art form during the A.D. 100's and 200's. The Romans spread mosaic art throughout the Roman Empire.

In the 500's, mosaics became the major decorative art form of the Byzantine Empire, which included parts of the eastern Mediterranean area. Mosaics of religious scenes decorated the walls and ceilings of many Byzantine churches. The finest Byzantine mosaics were made from the 900's to the 1300's. With the end of the Byzantine era in the 1400's, mosaic art declined. But it was revived during the mid- and late 1500's in the Italian cities of Florence and Rome.

Through the centuries, peoples of various other cultures have created mosaic art. For example, Muslims in India and Persia made mosaics, as did the Aztec and Mayan Indians of Latin America. Architects in Mexico have used mosaics to decorate modern buildings.

John W. Keefe

See also **Byzantine art; Indiana** (People [picture]); **Shell** (picture: Shell mosaic).

Mosaic disease, *moh ZAY ihk,* is the name of a group of plant diseases caused by certain viruses. The leaves of affected plants become mottled with light- and dark-green blotches. The disease usually stunts the growth of plants and may cause flowers to become streaked and twisted. Plants attacked by the disease include beans, carnations, corn, orchids, potatoes, sweet peas, tobacco, and wheat, and such weeds as burweed and milkweed. Insects called *aphids* often transmit the virus from diseased plants to healthy ones. People may spread certain mosaic viruses by handling plants after smoking tobacco products made from infected tobacco. There is no cure for diseased plants, and they should be removed. Such plants should never be used for cuttings because every part is infected. Jerry T. Walker

Mosby, *MOHZ bee,* **John Singleton** (1833-1916), was a famous Confederate ranger during the Civil War. He joined the Confederate cavalry in 1861, and began his independent ranger activities in 1863. His raids on Union bases and camps were so effective that part of north-central Virginia became known as "Mosby's Confederacy." After the war, Mosby practiced law and held several public offices. He was born in Powhatan County, Virginia. Frank E. Vandiver

The Good Shepherd (about A.D. 430) from the Mausoleum of Galla Placidia, Ravenna, Italy (Madeline Grimoldi)

An early Christian mosaic, *left,* portrays Jesus Christ as a shepherd. The sheep tended by Christ symbolize human souls. The detail shown above left illustrates how the unknown artist arranged many colored pieces to create the scene.

The center of Moscow contains many historic buildings. The Savior Tower, *with clock,* is a main entrance to the Kremlin, an old fortress that houses Russia's government. St. Basil's Cathedral, with its colorful spires, lies nearby. Red Square, *right,* is the site of many parades and other gatherings.

Moscow

Moscow, *MAHS kow* or *MAHS koh,* is the capital of Russia and one of the largest cities in the world. More than 8 $\frac{1}{4}$ million people live in Moscow. Moscow is the cultural, communications, government, industrial, scientific, and transportation center of Russia. It lies in western Russia, in the European part of the country. The Moscow River, for which the city was named, flows through the city.

Moscow emerged as the most powerful Russian city in the late 1400's. The princes of Moscow played a leading role in uniting various Russian lands and in conquering non-Russian peoples and territories. Moscow became the capital of the Russian Empire and was the home of Russia's *czars* (emperors) until 1712, when the capital was moved to St. Petersburg.

Moscow again became the Russian capital in 1918, after the Bolsheviks (later called Communists) took control of the country. In 1922, Russia and three other republics united to form the Union of Soviet Socialist Republics (U.S.S.R.). Moscow was chosen as the capital of the U.S.S.R., which grew to include 15 republics.

In 1991, the Communists lost power and the U.S.S.R. was dissolved. Russia and the other former Soviet republics became independent countries. Moscow remained the capital of Russia.

Jaroslaw Bilocerkowycz, the contributor of this article, is Associate Professor of Political Science at the University of Dayton and author of Soviet Ukrainian Dissent: A Study of Political Alienation.

The city

Layout of Moscow. Moscow is built in the shape of a wheel. This shape can be traced to the city's early history, when rings of fortifications were built to protect it from attack. Today, wide boulevards extend from the city's center, forming the spokes of the wheel. They cross circular boulevards, which make up the inner and outer rims of the wheel. A major highway circles Moscow. Past the highway lies the Green Belt, a ring of forests and parks covering about 695 square miles (1,800 square kilometers).

The oldest and busiest sections of Moscow lie near the Kremlin, a huge walled fortress at the city's historic center. Just north and east of the Kremlin is the main business, commercial, and administrative district. Encircling this area and the Kremlin are Moscow's main shopping streets and many cultural buildings. Most of the city's new residential and industrial districts lie in the outermost rings.

Famous landmarks. At the heart of the city stands the Kremlin. This old fortress was the center of the Sovi-

Facts in brief

Population: 8,297,900.
Area: 339 mi² (879 km²).
Climate: *Average temperature*—January, 15 °F (−10 °C); July, 65 °F (18 °C). *Average annual precipitation* (rainfall, melted snow, and other moisture)—25 in (64 cm).
Government: City Duma (council) of 35 members, elected to four-year terms. Mayor directly elected by the people.

et Union's government until that nation was dissolved in 1991. Since then, it has been the center of the Russian government. Inside its walls, which extend almost 1 ½ miles (2.4 kilometers), are beautiful cathedrals and palaces, as well as government buildings. Some of the cathedrals date from the 1400's. Many czars are buried in the Cathedral of the Archangel Michael. The Grand Kremlin Palace was built in the early 1800's as an imperial residence. The building later was the meeting place of the Supreme Soviet, the parliament of the Soviet Union. The Palace of Congresses, built in 1961, is used for cultural performances and government meetings and receptions. From 1961 to 1990, it also housed Soviet Communist Party meetings. See **Kremlin**.

Red Square lies just outside the Kremlin walls. This large plaza, about ¼ mile (0.4 kilometer) long, took its name in Russian from an old word meaning both *beautiful* and *red.* Huge military and civilian parades in Red Square celebrate various special occasions.

Opposite the Kremlin on Red Square is GUM, the country's largest department store. It was completed in the early 1890's and remodeled in 1953. The initials GUM come from three Russian words that mean State Department Store. St. Basil's Cathedral—a Russian church famous for its many colorful, onion-shaped domes—is also on Red Square. Originally built over 400 years ago to honor several military conquests, this building is now part of the State Historical Museum. The Russia Hotel, one of the world's largest hotels, is near Red Square. Russia's State Duma (parliament) building lies west of the Kremlin.

People

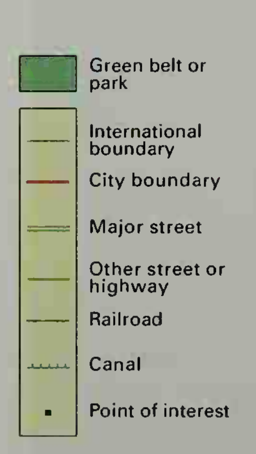
People of Moscow are called *Muscovites.* Moscow's population is a mixture of many nationalities. Russians are by far the largest group in Moscow. Other nationalities include Jews, Ukrainians, Tatars, Belarusians, and Armenians. Moscow does not have separate ethnic neighborhoods. The government has attempted to limit the number of people who live in Moscow.

Housing. Most Muscovites live in small, one- or two-room apartments. The majority of these apartments are in high-rise buildings erected since the 1950's. Despite the growth of housing units, Muscovites suffer housing shortages and complain of poor building quality. Families often wait years to get their own apartment. Some employers provide housing for their workers.

Education. Moscow has about 85 institutes of higher education, including about 30 universities. Two of the best-known universities are Moscow State University and the Russian Peoples' Friendship University. A variety of specialized institutes train students in specific fields, such as engineering or medicine.

Moscow State University ranks as the largest university in Russia. Established in 1755, it has about 28,000 students. The Russian Peoples' Friendship University, established in 1960, draws about a quarter of its students from foreign countries. Its focus shifted in the 1990's from the study of Communism to the study of market economics.

Like all Russian children, Moscow youngsters must attend school from age 6 to 17. Moscow has about 1,500 elementary schools and general high schools, and about 165 technical or vocational high schools.



Religion. From 1917 through the 1980's, the Communist government of the Soviet Union discouraged the practice of all religions. As a result, many Muscovites do not follow any religious faith. Many others, however, have continued to practice a religion. Most religious Muscovites of Russian nationality belong to the Russian Orthodox Church.

The Communists closed or destroyed many Orthodox

churches. Some were made into museums. In 1990, however, the Soviet government ended all religious restrictions. Places of worship that had been closed for decades reopened. Christ the Savior Cathedral, which had been destroyed by the Communists in 1931, was rebuilt. It reopened in 1997, and many Muscovites saw its rebuilding as a symbol of the rebirth of their city.

Non-Russian Muscovites belong to many religious groups, including Baptists, Jews, Muslims, and Roman Catholics. Moscow has a few Catholic and Protestant churches, Jewish synagogues, and Islamic mosques.

Social problems. During the late 1980's, crime became a growing problem in Moscow, partly due to the loosening of formerly strict police controls. The increase in crime also stemmed from economic hardships—including serious shortages of food, clothing, and other goods—which grew more serious during the 1990's. In addition, a high rate of alcoholism has fueled crime.

Homelessness has also become a problem in Moscow. The homeless people include refugees who have fled ethnic violence in other parts of the country.

Moscow has long suffered from pollution problems. For many years, the Soviet government emphasized industrial growth with little concern for the environment. Exhaust from factories and automobiles fouled the air. Poor water and sewage treatment also caused problems. Muscovites have begun using high-technology equipment and energy-saving devices to control pollution. They have also begun closing or moving some factories that pollute.

Cultural life

Arts. Moscow has long been a center of Russian and world culture. The Bolshoi Theater presents operas and ballets. The Bolshoi Ballet is internationally known and admired. Dancers from all over the country train at the Bolshoi Theater school. The Moscow State Symphony and other orchestras perform at the Tchaikovsky Concert Hall in Moscow. The city also has several famous theaters, including the Maly and Moscow Art theaters.

Museums and libraries. Moscow has more than 100 museums and many art galleries. The State Historical Museum attracts many students of Russian history. The Central Museum of the Revolution has exhibits on the Russian Revolution. The Armory Museum in the Kremlin displays dazzling treasures that belonged to the czars. The Tretyakov Gallery contains a collection of traditional art. The Russian National Exhibition Center highlights science and technology.

More than 500 main libraries operate in Moscow. The Russian State Library is the largest library in Russia and one of the largest in the world. See also **Library** (Eastern Europe and Russia; picture: Russian State Library).

Entertainment and recreation. Moscow has many recreational facilities. The huge Luzhniki Stadium sports complex was completed in 1956 and later expanded for the 1980 Olympics. The Luzhniki Stadium itself seats about 103,000 people. The stadium is used mainly for soccer, the country's most popular sport, and for track events. The athletic complex also includes swimming pools and smaller sports arenas.

Gorki Park is Moscow's most popular amusement center. It features an outdoor theater and facilities for boating, ice skating, and tennis. The park, which opened in 1925, covers about 300 acres (120 hectares).

The Arbat is a popular district of downtown Moscow. It has many small shops, restaurants, and bookstores. Folk music, roving artists, and political debates make the Arbat a lively section of town.

The Metro is Moscow's subway system. It is famous for its many elegant subway stations, each of which is decorated in a different style. The one shown here is the Kievskaya station.

Chess is a popular pastime for Muscovites, and many chess champions play at the city's Central Chess Club. The Moscow Zoo is a popular attraction. The Moscow Circus is one of the finest circuses in the world.

Economy

Many of the people of Moscow are employees of national or city government agencies. Other Muscovites work for factories or businesses that are controlled by the Russian government. Since 1991, many businesses in Moscow have come under private ownership. Some foreign businesses have begun operating in the city.

Manufacturing. Moscow is the most important industrial city in Russia. Its factories produce a wide variety of goods. These include automobiles, buses, chemicals, dairy products, electrical machinery, measuring instruments, processed foods, steel, textiles, and trucks.

Transportation. Moscow serves as Russia's transportation center. Highways and railways extend in all directions from the city to most parts of the country. Moscow has five major airports, the largest of which is in Domodedovo, south of the city. Sheremetyevo International Airport handles most international flights. The Moscow Canal links the city to the Volga, Europe's longest river.

The people of Moscow are proud of their subway system, the Metro. It has about 160 subway stations, which are the fanciest in the world. Many look like palace halls and are decorated with chandeliers, marble panels, paintings, stained glass, and statues. The Metro opened in 1935. It has about 160 miles (260 kilometers) of track. About 8 million passengers ride it daily.

Communications. Many magazines, journals, and newspapers are published in Moscow. These include the important national newspaper *Izvestia (News).* Other popular publications published in Moscow include the newspapers *Trud (Labor), Komsomolskaia Pravda (Youth Communist League Truth),* and the political magazine *Argumenty i fakty (Arguments and Facts). Evening Moscow* and the *Moscow News* are the city's local papers.

Radio Moscow, operated by the government, broadcasts programs on four channels. Russia's two major national television networks are also government operated and have their headquarters in Moscow. The city has several local channels and receives local programs from St. Petersburg. Moscow is home to some of Russia's new, privately owned radio and television stations.

Government

Moscow is governed by a City Duma (council) of 35 members elected to four-year terms. Each member represents an election district called a *ward.* The City Duma does much of its work in 10 regular committees. These committees deal with various economic, social, environmental, and organizational matters.

A mayor heads the executive branch of the Moscow city government. The mayor is assisted by a vice-mayor and several first-deputy and deputy mayors. The people of Moscow directly elect their mayor and vice-mayor, who serve four-year terms. The mayor and vice-mayor candidates run as a team.

The city administration also includes *prefects,* officials appointed by the mayor to administer city services and policies in 10 administrative regions. Moscow is further divided into 125 municipal districts.

Moscow has special status in Russia as a federal city, as does St. Petersburg. As a result, Moscow's mayor and the head of the City Duma also serve as members of the upper house of Russia's parliament.

History

The rise of Moscow. No one knows when Moscow was first settled. The first recorded reference to the town is in an early Russian historical chronicle under the year 1147. At that time, Moscow was a possession of Yuri Dolgoruki, a Russian prince who ruled the surrounding region. The town lay on important land and water trade routes, and it grew and prospered.

During the 1200's, Tatar invaders from Asia conquered Moscow and other Russian lands. The Russian

Sovfoto

Moscow in the 1100's was a wooden fortress on a hill. The Kremlin now stands at this location. The nearby Moscow River was an important trade route.

princes were forced to recognize the Tatars as their rulers and to pay them taxes. During the 1300's, the Moscow princes collected taxes in their region for the Tatars. The Moscow princes expanded their territory greatly by buying lands or seizing them from rival princes.

By the late 1400's, Moscow had become the most powerful Russian city. Moscow threw off Tatar control during the late 1400's under Ivan III (the Great). His grandson, Ivan IV (the Terrible), was crowned czar of all Russia in 1547. Moscow was his capital.

Moscow grew rapidly during the 1600's. The czars built palaces in the Kremlin, and nobles built mansions. New churches and monasteries arose, and industries developed. In 1712 Peter I (the Great), moved the capital to St. Petersburg. However, Moscow remained an important center of culture and trade.

Destruction and rebirth. In the fall of 1812, invading French troops under Napoleon I sought to capture Moscow. The French and Russian armies fought a major battle at Borodino, just outside Moscow. The French army won the battle and entered Moscow without a struggle. Most of the people had left the city. Soon afterward, fires destroyed most of Moscow. Historians believe that most of the fires were set by retreating Russians, but that others were started by looting troops from Napoleon's army. After about a month, the French troops left and began a disastrous retreat through the cold Russian winter. See **Napoleon I** (Disaster in Russia).

The rebuilding of Moscow began almost immediately. New residences were built, and factories began to appear. By the mid-1800's, Moscow had emerged as the railway and industrial center of Russia. The city's population grew rapidly, passing 1 million by 1900.

Early 1900's. In 1905 and in 1917, fierce revolutions against the czar took place in several Russian cities, including Moscow. In the 1917 revolution, the government fell to the Bolsheviks, who moved the capital back to Moscow in 1918.

Moscow grew rapidly during the 1930's. During World War II (1939-1945), German troops advanced almost to the city but never captured it. Governmental bodies and industrial factories were moved to the eastern part of the country. German air raids damaged Moscow, but severe winter weather and determined

© Shone, Gamma/Liaison

Jubilant Muscovites celebrated the failure of a coup in August 1991. Several Communist officials had tried to overthrow the Soviet president, Mikhail S. Gorbachev. But in December, Gorbachev resigned, and the Soviet Union was dissolved.

Soviet forces stopped the Germans in 1941. The Battle of Moscow was an important victory for the Soviet Union because it proved that the Germans could be defeated. See **World War II** (The invasion of the Soviet Union; On the Soviet front).

In 1960, Moscow's city boundaries were expanded, more than doubling the city's area. The 1980 Summer Olympic Games were held in Moscow, the only Soviet city ever to host the Olympics.

In 1990, Moscow held its first democratic election for the City Duma. Democratic reformers won a majority of the seats. In August 1991, several Communist officials attempted to overthrow Soviet President Mikhail S. Gorbachev. Moscow became the center of protests that helped to end the coup. In December 1991, Gorbachev resigned, and the Soviet Union was dissolved.

Recent developments. Christ the Savior Cathedral, destroyed by the Communists in 1931, reopened in 1997. Work continued on its interior in the early 2000's.

In 1999, explosions destroyed several apartment buildings and killed more than 200 people. Moscow officials blamed terrorists from the break-away republic of Chechnya, but conclusive evidence has never been found. Jaroslaw Bilocerkowycz

Questions

How did Moscow become the most powerful Russian city?
What is the Green Belt?
Which art form is the Bolshoi Theater most famous for?
What efforts has the city made to control pollution?
What is the Metro?
How many members serve in the City Duma?
Why was the Battle of Moscow important in World War II?
What makes Moscow the transportation center of Russia?
What is the Arbat?
Why did crime become a problem in Moscow in the 1980's?

Moscow Art Theater became one of the most influential theaters of the 1900's. It presents plays by major Russian authors and has made several tours of Western countries. One of its founders, Konstantin Stanislavski, developed his *Method* style of acting at the theater. The style stresses psychological realism in the interpretation and presentation of plays. In the Method style, actors and actresses define a role by saying, "If I were this character, I would. ..." They also define a role by drawing on relevant experiences from their own lives. The style has had great impact on Western theater.

The theater was founded in 1898 by Stanislavski and Vladimir Nemirovich-Danchenko. Its production of Anton Chekhov's *The Sea Gull* (1896) started his career as a successful playwright. Albert Wertheim

See also Stanislavski, Konstantin.

Moseley, *MOHZ lee,* **Henry Gwyn-Jeffreys,** *gwihn,* (1887-1915), was a British physicist noted for his research on X rays and atomic structure. About 1913, he discovered a systematic relationship between X-ray spectra and the atomic number of the elements giving off the X rays. This discovery enabled him to determine the atomic number of elements and to arrange them in the proper places in the periodic table. Moseley found four atomic numbers with no known elements—43, 61, 72, and 75. The elements that correspond to these numbers—technetium, promethium, hafnium, and rhenium—were discovered later. See Element, Chemical.

Moseley was born in Weymouth, England. He attended Oxford University and did research there and at the University of Manchester. Moseley was killed in action during World War I. Joel R. Primack

Moseley-Braun, *brawn,* **Carol** (1947-), was the first black woman elected to the United States Senate. A Democrat from Illinois, she held office from 1993 to 1999. Moseley-Braun, who was considered a liberal, won strong support from women in her election. She had decided to run for the Senate because she wanted to bring about change. She was unhappy with the fact that the Senate had confirmed Clarence Thomas as a justice of the Supreme Court of the United States despite charges he had sexually harassed a female co-worker. Moseley-Braun and California Senator Dianne Feinstein were the first women to serve on the powerful Senate Judiciary Committee. Moseley-Braun became known for her efforts to increase government support of education. She lost a bid for reelection to the Senate in 1998. From 1999 to 2001, she served as U.S. ambassador to New Zealand.

Carol Moseley-Braun

Moseley-Braun was born in Chicago. She earned a law degree from the University of Chicago in 1972 and was an assistant U.S. attorney from 1973 to 1977. She served in the Illinois House of Representatives from 1979 to 1989, when she became the recorder of deeds in Cook County, Illinois. Guy Halverson

Moselle River, *moh ZEHL,* a branch of the Rhine River, rises in the Vosges Mountains in eastern France. It flows northeastward for 319 miles (513 kilometers) and empties into the Rhine in Koblenz, Germany. It is called the *Mosel* in Germany. Much of the Moselle is shallow. A 170-mile (274-kilometer) canal enables barges to go about 200 miles (320 kilometers) up the river. The famous Moselle wines are made along the river's banks. Major ironworks and steelworks lie along the Moselle in eastern France. The beautiful river valley in Germany attracts many tourists. The Moselle was the scene of bitter fighting during World War I (1914-1918) and World War II (1939-1945). Frank Ahnert

Moses was the principal leader and teacher of the Israelites and one of the most important characters in the Bible. He led his people out of slavery in Egypt to their homeland in Canaan, later called Palestine. At Mount Sinai, Moses declared the Ten Commandments as the law for his people. There, the Israelites were established as a nation under Moses's leadership.

Moses was a political organizer, a military chief, a diplomat, a lawmaker, and a judge as well as a religious leader. He kept the Israelite nation united during its years of wandering in the desert between Egypt and Canaan. The Bible pays tribute to Moses in the following passage: "And there arose not a prophet in Israel like unto Moses, whom the Lord knew face to face, in all the signs and the wonders, which the Lord sent him to do in the land of Egypt to Pharaoh..." (Deuteronomy 34:10).

The first five books of the Bible—Genesis, Exodus, Leviticus, Numbers, and Deuteronomy—are called the "Five Books of Moses," or the *Pentateuch.* The story of Moses's life is in the books of Exodus, Leviticus, Numbers, and Deuteronomy. The books do not mention Moses as the author, however. Biblical scholars believe that the stories in the Five Books of Moses were passed orally from generation to generation until they were written down between about 1000 and 400 B.C.

Early life. Moses was born in Egypt near the end of the 1300's B.C. He was the descendant of Hebrew slaves who had migrated from Canaan to Egypt hundreds of years earlier. The Egyptians had enslaved the Hebrews and forced them to build large cities and palaces.

According to the Bible, the population of the Hebrews eventually grew so large that the Egyptian pharaoh feared they could not be controlled. Therefore, at about the time of Moses's birth, the pharaoh ordered all male Hebrew children killed. Moses's mother hid her baby in a basket in the rushes on the bank of the Nile River. The pharaoh's daughter found the infant and raised him, with the help of Moses's own mother. This account of Moses's escape from death shows that he would become a great man.

Moses was given an Egyptian name and received an Egyptian education, but he retained his Hebrew identity.

As an adult, Moses saw an Egyptian beating a Hebrew. He killed the Egyptian and fled into the desert. While living there, he married Zipporah, the daughter of Jethro, a priest of the Midianite tribe. They had two sons, Gershom and Eliezer.

Moses settled in the land of Midian. There, he lived as a shepherd. One day, according to the Bible, God spoke to him from a burning bush. He commanded Moses to return to Egypt and lead the Hebrews to the land that had been promised to Abraham, the ancestor of the Hebrews (see **Abraham**). Moses argued that he could not perform such a difficult project. However, Moses accepted God's commandment to lead the Hebrews from Egypt.

The Exodus. Moses joined his older brother, Aaron, while returning to Egypt, and they met with the pharaoh. Moses reportedly told the pharaoh, "Let my people go" (Exodus 5:1), but the Egyptian ruler refused to do so. He punished the Hebrews by increasing their workload.

According to the Bible, the Egyptians were then afflicted with nine terrible plagues. But after each one, the pharaoh continued to refuse to let the Hebrews leave. The 10th and final plague killed the pharaoh's oldest son and all first-born Egyptian sons. But the Hebrews remained unharmed.

The 10th plague caused the pharaoh and the Egyptian people great grief. The pharaoh finally agreed to let the Hebrews leave Egypt. Their flight from Egypt is called the *Exodus.* The pharaoh soon regretted losing so many slaves and sent his army to recapture them. According to the Book of Exodus, God led the Hebrews through the wilderness to a body of water traditionally identified as the Red Sea. However, because the Hebrew text actually says "sea of reeds," most modern scholars believe the body of water was actually the marshy lands east of the Nile Delta, well north of the Red Sea. As the pursuing Egyptians drew closer, God commanded Moses to lift a rod and stretch his hand over the sea to divide the waters. The parting of the waters enabled his people to cross safely. The Egyptian soldiers followed the Hebrews but drowned when the waters flowed back into place.

The covenant with God. Moses led the Hebrews across the Red Sea into the desert. They journeyed to Mount Sinai, where they entered into a *covenant* (agreement) with God. Under the terms of the covenant, the Hebrews became the new nation of Israel. The covenant provided that all the Israelites would live under God's eternal love and protection. In exchange, they would be ruled by God and obey His laws.

The basis of the covenant consisted of the Ten Commandments and laws found in the "Book of the Covenant," a set of God-given rules and guidelines. According to the Bible, Moses received the Ten Commandments and other laws from God on Mount Sinai. The Ten Commandments and the laws of the "Book of the Covenant" became part of what is known as the "Torah of Moses." These laws defined the Israelites' relationship with one another and with God. Moses also established an administrative and legal system for the Israelites to help carry out the laws of the covenant.

While Moses was receiving the Ten Commandments, the Israelites became impatient. They wanted a god that they could see. As a result, the Israelites built a golden calf and began to worship it. The Israelites thought the golden calf represented the God who had led them out of Egypt.

After Moses came down from the mountain, he found his people dancing before the idol. He became so angry that he smashed the stone tablets on which the Ten Commandments had been inscribed. Many Israelites died soon afterward, and the people believed that the deaths were a punishment for their sin. God later gave Moses a new copy of the Ten Commandments on other stone tablets.

The Biblical story also describes how Moses organized the nation's official forms of worship. The Israelites' religious activities centered on a movable structure called the *Tabernacle.* The Tabernacle served as an official meeting place for God and the people, and it symbolized His relationship with the Israelites (see **Tabernacle**). The people reestablished the old Hebrew holidays as national celebrations. The Exodus became a theme of the renewed festivals. The springtime holiday *Passover* celebrates the Israelites' escape from Egypt (see **Passover**).

Journey to Canaan. The Israelites are reported to have spent 40 years wandering in the desert between Egypt and Canaan. They lived under harsh conditions and often complained to Moses. The people also became impatient and frustrated, and they challenged Moses's authority as a religious and political leader. In addition, they questioned their faith in a God they could not see.

Miniature (about 1320) from the *Golden Haggadah* of Barcelona, Spain; British Library, London

Moses was an Israelite leader. This painting shows events from his life. At the upper right, an angel in a burning bush appears to Moses. At the upper left, Moses and his wife return to Egypt from Midian and meet his brother Aaron. At the lower right, the brothers perform a miracle for the elders of Israel. At the lower left, Moses and Aaron appear before the pharaoh.

Moses often asked for God's help to care for his people. He frequently obtained food and water for the Israelites under God's direction. Throughout their long wanderings in the desert, Moses served as an intermediary between God and the Israelite people.

Hostile tribes apparently attacked the Israelites several times in the desert, but Moses always led his people to victory. He also foresaw the many difficulties that the Israelites would encounter in Canaan.

When the Israelites reached Canaan, God allowed Moses to see the new land but not to enter it. According to the Bible, Moses did not cross the River Jordan into Canaan because he had not followed one of God's instructions (Numbers 20:1-13). God had told Moses to obtain water for the Israelites by speaking to a rock. Water would then flow from the rock. But instead of speaking to the rock, Moses struck it. Since God would not allow Moses to enter Canaan, Joshua, an assistant of Moses, led the people into Canaan.

Moses died in God's favor at an advanced age. According to the Book of Deuteronomy, God buried Moses on Mount Nebo in the desert. Carol L. Meyers

Moses, Grandma (1860-1961), was an American folk artist. She started painting when she was in her 70's and remained active until near her death. Grandma Moses never had a formal art lesson. Her paintings were generally simple but realistic scenes of rural life. These colorful and lively pictures were based on memories of her own youth in the late 1800's. Critics have praised her work for its freshness, innocence, and humanity.

Grandma Moses was born Anna Mary Robertson in Washington County, New York. She married Thomas Salmon Moses in 1887. For many years, she embroidered pictures on canvas. She began to paint when arthritis made it hard to hold embroidery needles.

An art collector first discovered Grandma Moses's paintings in the 1930's. She was represented in a show at the Museum of Modern Art in New York City in 1939. Her first one-artist show was in 1940. Her autobiography, *My Life's History,* was published in 1952.

Mosquitoes live throughout the world. Certain kinds transmit diseases when they "bite." These photographs show an *Anopheles* mosquito, *top,* and a *Culex, bottom.* Some *Anopheles* mosquitoes carry malaria. *Culex* mosquitoes transmit encephalitis.

in a community. Mosques also have served as places of religious instruction, as tombs, and as temporary homes for traveling scholars.

A typical mosque has a courtyard surrounded by four halls called *iwans.* In most cases, there is a fountain or well for ceremonial washing in the courtyard. The inner wall closest to the holy city of Mecca has a decorative niche or arch called a *mihrab,* which indicates the direction Muslims must face when praying. In numerous mosques, flat surfaces are decorated with painted or tile patterns or with scriptural quotations in elegant handwriting called *calligraphy.* Most mosques have from one to six towers called *minarets,* from which *muezzins* (criers) call the faithful to prayer. Many mosques contain a pulpit, called a *minbar.* William J. Hennessey

Mosquitia. See Mosquito Coast.

Mosquito is an insect that spreads some of the worst diseases of people and animals. Certain kinds of mosquitoes carry the germs that cause such serious diseases as encephalitis, malaria, filariasis, and yellow fever. When a mosquito "bites," it may leave germs behind. Many kinds of mosquitoes do not spread diseases, but they have painful "bites." Many of the mosquitoes that are associated with disease live in the hot, moist lands near the equator. But mosquitoes are found in all parts of the world, even in the Arctic.

There are more than 3,000 species of mosquitoes. About 150 species live in the United States. Biologists classify species of mosquitoes into about 35 groups, each called a *genus.* For example, the common house mosquito, which may transmit certain kinds of parasitic worms, belongs to the genus *Culex.* This species and other members of its genus may also carry encephalitis viruses. Some mosquitoes in the genus *Anopheles* carry malaria, and some in the genus *Aedes* transmit yellow fever virus.

People control insects in many ways. Small amounts of chemical insecticides kill mosquitoes when sprayed in homes, garages, and other buildings. Thick mists of insecticides may be sprayed into fields, forests, and gardens. People also control mosquitoes by destroying the places where they breed. Mosquitoes lay their eggs in marshes, swamps, and pools of still water, and tree holes, tires, and tin cans that contain standing water. Such places may be drained, or the surface of the water may be covered with thin layers of oil or insecticides.

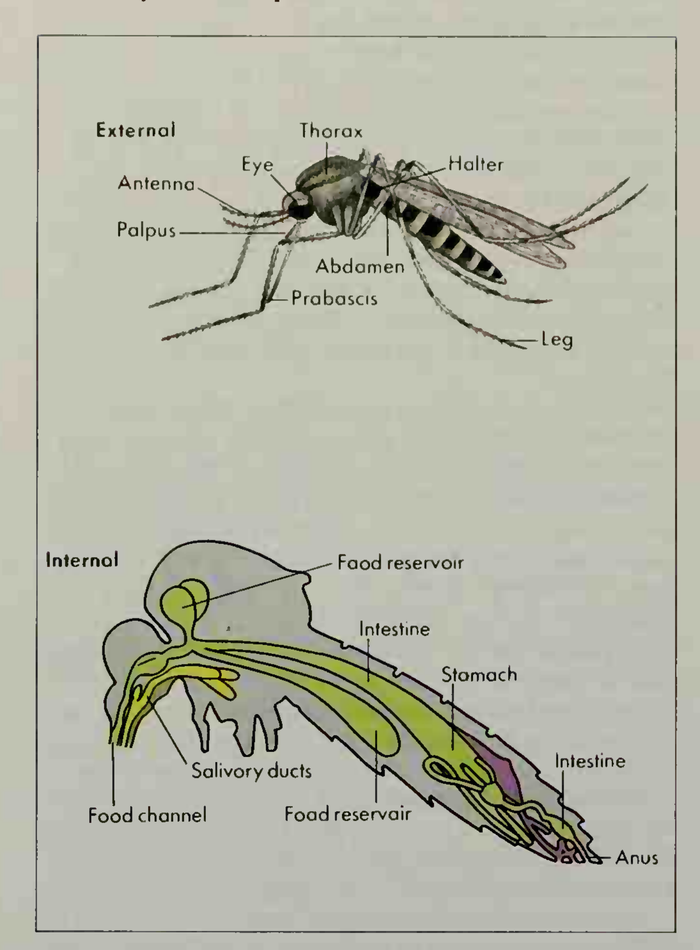
Since the 1960's, scientists have turned increasing attention to the biological control of insects, including mosquitoes. Programs are designed to control certain insects without damaging other elements of the environment. One such program uses fish that eat mosquito *larvae* (young). Another uses the spores of a bacterium, *Bacillus thuringiensis,* to kill the larvae.

Most kinds of mosquitoes are from $\frac{1}{8}$ to $\frac{1}{4}$ inch (3 to 6 millimeters) long. One of the largest is the American gallinipper. It grows about $\frac{5}{8}$ inch (16 millimeters) long.

The hum of a mosquito is the sound of its wings beating. A mosquito's wings move about 1,000 times a second. A female's wings make a higher tone than a male's wings, and the sound helps males find mates.

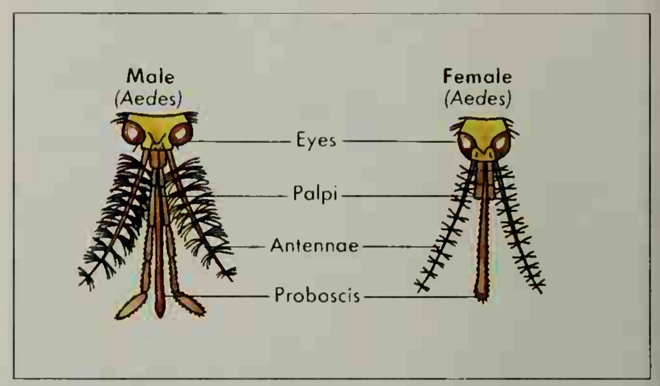
Mosquitoes are *flies* (insects with two wings). The word *mosquito* is Spanish and means *little fly.*

The body of a mosquito



The mosquito's slender body has three parts: (1) the head, (2) the thorax, and (3) the abdomen. The insect's body wall is thin and elastic. Fine hair and thin scales grow on the body and on the wings. Most kinds of mosquitoes are black, brown, gray, or tan. Many species have white or light-colored markings on their backs, legs, or wings. A few kinds are bright blue or green, and seem to shine with coppery or golden lights.

Head. The mosquito has a large, round head that is joined to the thorax by a short, thin neck. Two huge *compound* eyes cover most of the head. These eyes, like those of most other kinds of insects, are made up of thousands of six-sided lenses. Each lens points in a



Facts in brief

Number of eggs: 100 to 300 at a time, depending on species. As many as 1,000 a year for each female.
Length of life: Up to 30 days or more for females; about 7 to 10 days for males.
Where found: All parts of the world.
Scientific classification: Mosquitoes belong to the fly order Diptera. They make up the family Culicidae.

The heads of mosquitoes

How a mosquito "bites"

A mosquito stabs a victim's skin with sharp stylets hidden in the proboscis. As the insect pushes the stylets down, they curve and enter a blood vessel. The *labium* (lower lip) slides out of the way.

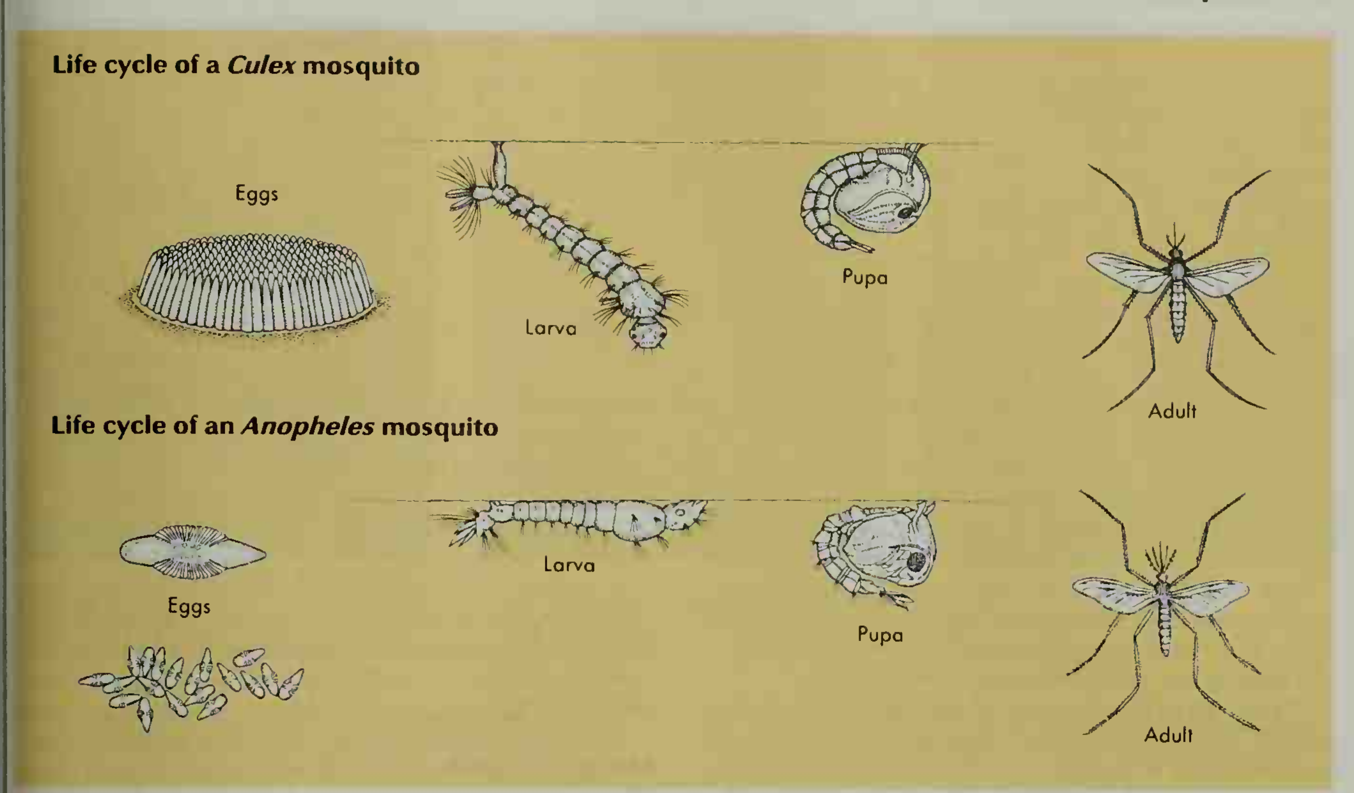
WORLD BOOK illustrations by Oxford Illustrators Limited

slightly different direction and works independently. A mosquito cannot focus its eyes for sharp vision, but it quickly sees any movement. The eyes are always open, even when the insect rests.

A mosquito hears and smells with its two antennae, which grow near the center of its head between the eyes. The antennae of a female mosquito are long and covered with soft hair. The male's antennae are also long, and have bushy hairs that give a feathery appearance.

The mouth of a mosquito looks somewhat like a funnel. The broadest part is nearest the head, and a tubelike part called the *proboscis* extends downward. A mosquito uses its proboscis to "bite," and as a straw to sip liquids, its only food. The males and females of many species sip plant juices.

How a mosquito "bites." Only female mosquitoes "bite," and only the females of a few species attack human beings and animals. They sip the victim's blood, which they need for the development of the eggs inside their bodies.



Mosquitoes do not really bite because they cannot open their jaws. When a mosquito "bites," it stabs through the victim's skin with six needlelike parts called *stylets,* which form the center of the proboscis. The stylets are covered and protected by the insect's lower lip, called the *labium.* As the stylets enter the skin, the labium bends and slides upward out of the way. Then saliva flows into the wound through channels formed by the stylets. The mosquito can easily sip the blood because the saliva keeps it from clotting. Most people are allergic to the saliva, and an itchy welt called a "mosquito bite" forms on the skin. After the mosquito has sipped enough blood, it slowly pulls the stylets out of the wound, and the labium slips into place over them. Then the insect flies away.

The amount of blood taken varies greatly among individual mosquitoes. Some may sip as much as $1\frac{1}{2}$ times their own weight at a time.

Thorax. The mosquito's thorax is shaped somewhat like a triangle, with the broadest part above and the narrowest part underneath. Thin, flat scales of various colors form patterns on the upper part of the thorax of certain kinds of mosquitoes. These patterns help identify different species. One kind of mosquito that spreads yellow fever has a U-shaped pattern formed by white scales on a background of dark scales.

Strong muscles are attached to the inside wall of the thorax. These muscles move the mosquito's legs and wings. A mosquito has six long, slender legs, and each leg has five major joints. A pair of claws on each leg helps the insect cling to such flat surfaces as walls and ceilings. The mosquito uses all its legs when it walks, but usually stands on only four of them. Many kinds of mosquitoes rest on their four front legs. Some kinds hold their two hind legs almost straight out behind them, but others curve their legs over their backs. White scales form bands on the legs of some species.

Mosquitoes have two wings, unlike most other kinds of insects, which have four wings. The wings are so thin

WORLD BOOK illustration by Patricia Wynne

that the veins show through. The veins not only carry blood to the wings, but also help stiffen and support them. Thin scales cover the veins and the edges of the wings. The scales rub off like dust when anything touches them. Some species of mosquitoes may have scales of beautiful colors.

Instead of hind wings, which most other insects have, a mosquito has two thick, rodlike parts with knobs at the tips. These parts, called *halteres,* give the mosquito its sense of balance. The halteres vibrate at the same rate as the wings when the insect flies.

A mosquito lifts itself into the air as soon as it beats its wings. It does not have to run or jump to take off. In the air, the mosquito can dart quickly and easily in any direction. The halteres keep the insect in balance. A mosquito must beat its wings constantly while it is in the air. It does not glide during flight or when coming in for a landing as do butterflies, moths, and most other flying insects. A mosquito beats its wings until its feet touch a landing place.

Abdomen of a mosquito is long and slender, and looks somewhat like a tube. Some kinds of mosquitoes have an abdomen with a pointed end. Other kinds have an abdomen with a rounded end. The shape of the abdomen helps scientists identify the species.

A mosquito breathes through air holes called *spiracles* along the sides of its body. The abdomen has eight pairs of spiracles, and the thorax has two pairs. Air flows into the holes, and tubes carry the air from the spiracles to all parts of the mosquito's body.

The life of a mosquito

A mosquito's life is divided into four stages: (1) egg, (2) larva, (3) pupa, and (4) adult. At each stage the mosquito's appearance changes completely, and the insect lives a different kind of life. In warm climates, some species develop from newly hatched eggs into adults in only a week. In the cold climate of the far north, mosquito eggs may remain dormant from autumn until late spring. They hatch in May or June, and take a month or more to grow into adults.

Egg. A female mosquito lays from 100 to 300 eggs at a time, depending on the species. One female may lay as many as 3,000 eggs during her lifetime. The eggs are laid through an opening at the tip of the female's abdomen. The females of most species of mosquitoes lay their eggs in water or near it, but each species has a favorite spot. Some like quiet swamps, and others prefer salt marshes. Still others lay their eggs in hidden pools that form in tin cans, rain barrels, gutters, fallen logs, or hollow tree stumps.

Among some species, the females drop their eggs one at a time. Frilly, transparent parts on the shell keep each egg afloat until it hatches. The females of other species arrange their eggs in groups that look somewhat like rafts. The female rests on the surface of the water while she lays her eggs, which are narrow at the top. With her hind legs, she carefully pushes the eggs, wide ends downward, into raftlike groups. The eggs of most kinds of mosquitoes hatch in two or three days in warm weather.

All mosquito eggs must have moisture to hatch, but not all species lay their eggs in water. Certain mosquitoes, called floodwater mosquitoes, drop their eggs in moist soil on flood plains and on irrigation sites. The eggs hatch after a flood takes place—perhaps a year later. Other species, sometimes called pond mosquitoes, lay their eggs in hollow places left by ponds that have dried up. The eggs hatch after rains fill the ponds with water. Not all of the eggs of these mosquitoes hatch after the first rain. They must be soaked by a second or even a third rain before they hatch into larvae.

Larva of a mosquito is often called a *wriggler* because it is so active. The wrigglers of most species move

about by jerking their bodies through the water.

A wriggler looks somewhat like a worm or a caterpillar. A thin, skinlike shell covers its body. The wriggler has a broad head, with two short, bushy antennae on each side. It has two eyes behind the antennae, near the back of the head. Its mouth is on the underside of the head, near the front. Long hairs called *mouth brushes* grow around the jaws and sweep food into the wriggler's mouth. Unlike an adult mosquito, a wriggler can open its jaws and chew its food. It eats tiny aquatic life, including one-celled organisms called *protozoans,* and other wrigglers.

A wriggler breathes through a tubelike *siphon* (air tube) at the rear of its body. To get air, it pushes its siphon above the surface of the water.

The larvae of certain swamp mosquitoes do not have to come to the surface for air. They get air from the leaves, stems, and roots of various underwater plants. The larva of one kind of swamp mosquito has a breathing tube with two sharp tips. It uses one tip to hold itself to the plant, and moves the other tip back and forth in the plant tissue to get the oxygen stored there.

The larvae of many species of mosquitoes grow quickly. They *molt* (shed their skins and grow new ones) four times in 4 to 10 days. After the last molt, the larvae change into pupae. The larvae of some species spend the winter in hibernation. They change into pupae early in spring.

Pupa. A mosquito pupa is shaped somewhat like a comma. The head and thorax are rolled into a ball, and the abdomen hangs down like a curved tail. A thin "skin," like that of the larva, covers the pupa's body. The pupa breathes through trumpet-shaped tubes attached to the top of its thorax. The pupa sticks these tubes out of the water to get air. The pupa of certain swamp mosquitoes, whose larva gets air from underwater plants, pushes its tubes into the plant. After this pupa has changed into an adult, it pulls out the tubes or breaks them off and leaves them in the plant. The pupa then swims to the surface.

The pupae of most species of insects do not move, but almost all kinds of mosquito pupae can swim. These pupae are sometimes called *tumblers* because they roll and tumble in the water.

A mosquito pupa does not eat. It changes into an adult in two to four days. The pupal "skin" splits down the back, and the adult mosquito pushes its head and front legs out. The insect then pulls out the rest of its body.

Adult. After the adult mosquito leaves the pupal "skin," its wings dry quickly and it flies a short distance away. Most species of mosquitoes spend their whole lives within 1 mile (1.6 kilometers) of the place where they hatched. A few kinds may travel as far as 20 miles (32 kilometers) away to find food or mates.

A female mosquito attracts a mate by the high-pitched sound made by her wings. The males are deaf for the first 24 to 48 hours of their lives, until the hairs on their antennae are dry.

The females of some species must sip blood before they can lay eggs that will hatch. Each species of female prefers the blood of certain kinds of animals. Some feed only on frogs, snakes, or other cold-blooded animals. Other mosquitoes prefer birds. Still other mosquitoes suck the blood of cows, horses, and people.

Male mosquitoes may live only about 7 to 10 days, but females may live up to 30 days or more. The females of some species live through the winter in barns, garages, houses, caves, or in the bark of logs. Some species spend the winter as eggs or as larvae. They develop into adults in spring. E. W. Cupp

Mosquito Coast, also called Mosquitia, is a strip of land that lies along the east coast of Nicaragua and the northeast coast of Honduras. It has an area of over 32,500 square miles (84,175 square kilometers) and extends for about 200 miles (320 kilometers) from the San Juan River in Nicaragua to the Aguan River in Honduras. The southern part makes up the department of Zelaya in Nicaragua. The northern part lies in the departments of Gracias a Dios and Colon in Honduras. The Mosquito Coast received its name from the Miskito (also spelled *Mosquito*) Indians. Gary S. Elbow

Moss is any of a variety of small, green, nonflowering plants found throughout the world. Mosses tend to grow close together in large numbers. They often form soft, dense mats on rocks, trees, or soil. Most mosses live on land in moist, shady places. But some are found in dry environments, and others grow in lakes, ponds, or rivers. Mosses generally measure less than 6 inches (15 centimeters) in height.

There are more than 9,000 species of mosses. Distinctive groups of species include *granite mosses* and *peat mosses.* Granite mosses are found on rocks in mountainous regions and the Arctic. Peat mosses grow in moist woodlands and in such marshy areas as bogs and fens. Other distinctive mosses include the *haircap moss* and the *feather moss.* Haircap mosses grow chiefly on soil, often in thick tufts. Feather mosses sometimes form dense carpets covering large areas of ground.

Other kinds of plants have the word *moss* as part of their common name but are not really mosses. These plants include Spanish moss, reindeer moss, and club mosses. See **Club moss; Reindeer moss; Spanish moss.**

The structure of mosses. Unlike flowering plants, mosses do not have true roots. But they have threadlike structures called *rhizoids* that anchor the plants and absorb water and nutrients. Most plants have short stems that produce rhizoids. The stems are covered by tiny leaves in a spiral pattern. The leaves absorb water and nutrients directly through their surface from the atmosphere. These leaves also contain chlorophyll, a green substance the plant uses to make food. In many cases, a vein runs the length of the leaf from the stem to the tip. This vein, called the *costa* or *midrib,* strengthens the leaf and transports food and water.

How mosses live. Mosses often grow in moist or aquatic environments, and they are more abundant in old forests than in young ones. However, certain mosses can survive extremely dry conditions. Their need for water changes with the amount of water available in the environment. During dry periods, mosses may turn dull

Runk/Schoenberg from Grant Heilman

Robert McKenzie, Tom Stack & Assoc.

Tom and Pat Leeson, Photo Researchers

Mosses tend to grow in bunches, and they often form dense mats that cover large areas. There are more than 9,000 species of mosses worldwide. Three types of mosses common in North America are peat moss, *left,* granite moss, *center,* and haircap moss, *right.*

brown and appear dead. But they become green and fresh-looking again as soon as it rains. Other, short-living mosses are found in prairies and other habitats that have exceptionally dry summer months. These mosses grow during the rainy months of spring and die when summer begins.

Mosses grow and reproduce in two phases—as *sporophytes* and *gametophytes.* This kind of life cycle is called *alternation of generations.*

During one phase, the moss plant is called a gametophyte. The gametophyte is the plant familiarly recognized as the moss. A mature gametophyte produces *gametes* (male sperm cells or female egg cells). The gametes form in special organs that grow from the top or along the side of the stem. The organs that produce sperm cells are called the *antheridia.* Those that produce egg cells are known as the *archegonia.* About half of all mosses bear both antheridia and archegonia on the same plant. When the antheridia become ripe and damp enough, they burst and release hundreds of sperm cells. Some of these cells may reach an archegonium, where one may unite with an egg cell to form a *zygote.*

John Shaw, Tom Stack & Assoc.

Sporophytes of haircap mosses rise high above the ground, as shown here. Each sporophyte consists of a long stalk ending in podlike capsules that contain tiny, seedlike spores.

The formation of the zygote begins the second phase of the moss life cycle. During this phase, the zygote develops into a sporophyte that remains attached to the gametophyte. It consists of a long, erect stalk called a *seta,* with a podlike *capsule* at the end. Microscopic structures called *spores* form in the capsule. A capsule may contain from four to more than a million spores, depending on the species.

In most mosses, the mouth of the capsule is covered by a lidlike *operculum.* In peat mosses, when the spores ripen, the operculum comes off explosively and the spores shoot into the air. In most other mosses, tiny toothlike structures around the mouth of the capsule control the release of spores. These structures, called the *peristome,* remain closed under wet conditions. In dry conditions, they open to discharge spores. If a spore falls on a damp area, it may sprout into a branching, threadlike *protonema.* Buds from the protonema then grow into gametophytes, completing the life cycle.

The importance of mosses. Mosses play an important part in the lives of many small animals. A number of small animals, including certain mites and spiders, live in mosses. Some birds use moss fibers to build or line their nests. Weevils in New Guinea have been found with mosses growing on their backs. The mosses serve as camouflage for these insects.

Mosses also help the environment. Some types, including peat mosses, can hold large quantities of water. This characteristic helps prevent soil erosion and flooding. Mosses also store minerals and other nutrients. After mosses die, they *decompose* (break down) and release nutrients. Other plants then use some of these nutrients to grow.

In various regions of the world, decaying mosses and other plant matter accumulate in low-lying areas over numerous years and form peat. Many such peat lands exist in Canada, Russia, and northern Europe. See **Peat.**

Peat mosses have a spongy texture and are very ab-

Motels serve millions of guests every year. Most motels are located near highways, on the outskirts of towns, or near airports. All motels provide free parking facilities, and many have restaurants. Some, such as the motel shown here, have swimming pools.

Artstreet

sorbent. Many gardeners use them to keep young plants from drying out. Peat moss is also used in the cultivation of mushrooms. In the past, some American Indians made diapers out of peat mosses. During World War I (1914-1918), peat mosses were used as dressings for wounds. See **Peat moss**. Dale H. Vitt

Mössbauer, *MAWS bow uhr,* **Rudolf Ludwig** (1929-), a German physicist, shared the 1961 Nobel Prize in physics for research into gamma rays. He discovered the "Mössbauer Effect," a method of producing gamma rays with a precise, predictable wavelength. This enables physicists to use gamma radiation to make precise measurements. The "Mössbauer Effect" was later used to confirm some predictions made by Albert Einstein in his relativity theory.

Mössbauer was born on Jan. 31, 1929, in Munich. He received his Ph.D. from the technical institute there. He became professor of experimental physics at the institute (now called the Technical University of Munich) in 1964. Richard L. Hilt

Motel is an establishment that provides overnight lodging, chiefly for automobile travelers. Most motels are located near busy interchanges of major highways, on the outskirts of towns, or near airports. All motels provide free parking facilities from which guests can reach their rooms directly. Some motels have restaurants and swimming pools.

The word *motel* comes from a combination of the words *motor* and *hotel.* Motels are also called *motor hotels, motor inns,* or *motor lodges.* The United States has more than 15,000 motels. Canada has about 4,000.

The number of rooms in a motel can range from fewer than 10 to more than 200. Many large motels are in the downtown areas of cities. Most of them provide the same services and charge approximately the same rates as commercial hotels (see **Hotel** [Commercial hotels]). On the other hand, most roadside motels offer fewer dining and other services, and they charge lower rates than the majority of hotels. The casual atmosphere of these motels, plus their convenient location on or near highways, appeals to large numbers of motorists.

Most motels do not require reservations because many automobile travelers cannot be sure where they will spend the night. Almost all roadside motels have large signs that tell whether vacant rooms are available. Motorists can see these signs and do not have to leave their cars to find out if a motel has any vacancies.

Roadside motels use highway billboards to advertise their location and the services they provide. These billboards are often located at various points for several miles along the major highways leading to a motel.

The first motels, called tourist cabins, were established during the early 1900's, when people began to travel by automobile. Tourist cabins originated in the Western United States, where people could not travel the long distances between towns in one day. These establishments also served fishermen, hunters, and other vacationers in remote areas.

The motel industry grew rapidly during the mid-1900's. People began to travel longer distances by car and needed places to stay along the way. The establishment of motel chains, which consist of two or more motels owned by one person or company, also stimulated motel development.

Through the years, several major motel chains have expanded by means of franchises. Under this system, an individual or a company buys a franchise—that is, the right to own and operate a motel in the chain. The purchaser runs the motel in the same manner and under the same name as the other motels in the chain. The franchise owner pays the chain a percentage of the motel's income. The owner has the advantage of operating a motel with a well-known name and reputation.

In the 1970's, several companies established chains of budget motels. The rates at these motels may be as low as half of those of other motels. Budget motels have small rooms and provide fewer services than more expensive motels. They do not have restaurants, and many have no swimming pools. Some budget motels in areas with cool climates do not provide air conditioning.

Eyespots

Edward S. Ross

Bumblebee sphinx moth

Various defenses protect moths from their enemies. The wings of some moths have markings called *eyespots* that may scare away an enemy. The bumblebee sphinx moth looks so much like a bumblebee that enemies often avoid it. Many moth caterpillars also have defenses, such as sharp spines, to protect them from harm.

Cameraria hamadryadella $\frac{1}{3}$-inch (0.8-centimeter) wingspread

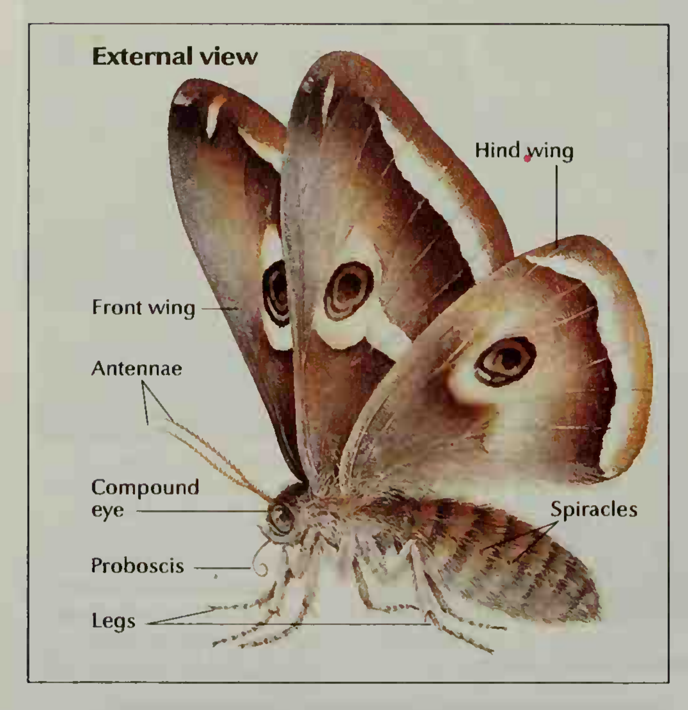
Moth is any of a wide variety of insects closely related to butterflies. All butterflies and almost all moths have two pairs of wings—a pair of large front wings and a pair of smaller hind wings. Moths and butterflies together form the insect group *Lepidoptera*. The name *Lepidoptera* comes from two Greek words: *lepis,* meaning *scale;* and *pteron,* meaning *wing.* The name refers to the fine, powdery scales that cover the wings of butterflies and moths.

Moths live throughout the world, except in the oceans. They inhabit steamy jungles near the equator, and they have even been found on icecaps in the Arctic. Moths vary greatly in size. The largest moths are the *giant Hercules moth* of Australia and the *giant owl moth* of South America. They have a wingspread of about 12 inches (30 centimeters). The smallest moths have wingspreads of about $\frac{1}{8}$ inch (0.3 centimeters). These moths belong to a group called *leafminers.*

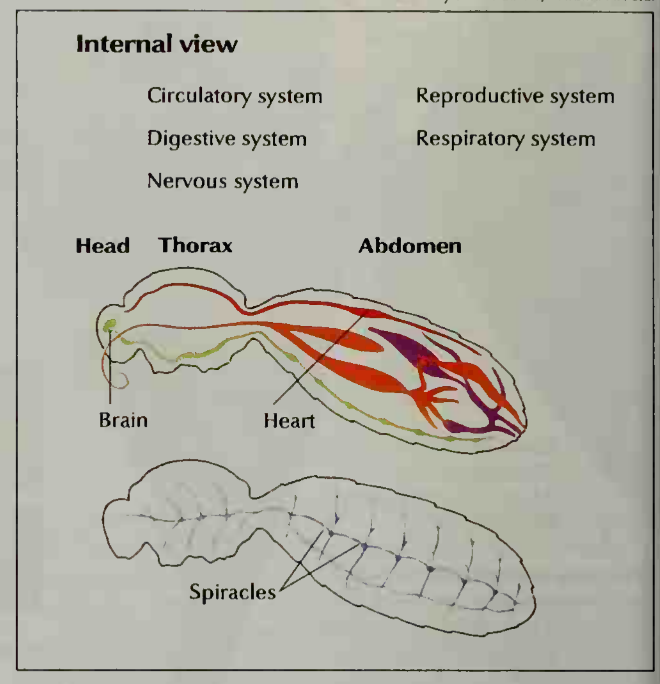
Like butterflies, moths change in form as they develop into adults. Only the adult form of a moth has wings. Female adult moths lay many tiny eggs that hatch into wormlike caterpillars. Most caterpillars eat almost constantly and grow rapidly. Some of them hibernate and take months or years to develop into adults. When fully grown, many moth caterpillars form a cocoon made of silk around themselves. The caterpillar then becomes a *pupa* by shedding its skin and creating a shell-like covering around itself. The insect goes through its final changes inside its pupal covering. Eventually, the moth breaks out of the covering as a fully developed adult.

Moths differ from butterflies in a number of important ways. For example, most moths fly at dusk or at night. The majority of butterflies fly during the day. Among most moths, the hind wing is attached to the front wing by a hook or set of hooks called a *frenulum.* Butterflies lack a frenulum. In addition, most butterflies have antennae that widen at the ends and resemble clubs. The antennae of most moths are not club-shaped. Many male moths have larger antennae than do female moths.

Some moths are regarded as pests because their caterpillars feed on and damage trees, food plants, or clothing. However, moths play important roles in nature, and some are valuable to people. Many adult moths pollinate flowers. Numerous birds rely on moth caterpillars as their main food. People use caterpillars of certain moths to produce silk, which comes from the cocoons.



The bodies of moths



A moth's body, like that of any insect, has a hard, shell-like skin called an *exoskeleton* (outer skeleton). The exoskeleton supports the body and protects the internal organs. Also like other insects, moths have bodies made up of three main parts: (1) the head, (2) the thorax, and (3) the abdomen.

The anatomy of a moth

A moth's body has three main parts: (1) head, (2) thorax, and (3) abdomen. The head bears the major sense organs, the thorax supports the wings and legs, and the abdomen contains internal organs. These drawings show external and internal features of a male white-streaked saturnia moth.

WORLD BOOK illustration by Stuart Carter, Wildlife Art Ltd.

The life cycle of a moth

A moth goes through four stages of development: (1) egg, (2) larva, (3) pupa, and (4) adult. A female moth lays many tiny eggs, which hatch into larvae, or caterpillars. A caterpillar spends its life eating and growing. When grown, it forms a shell-like covering and becomes a pupa. The insect undergoes its final changes within this covering. It emerges from the shell as an adult. These photos show stages in the development of a *Cecropia* moth.

Pupal covering and adult

The head bears the moth's eyes, antennae, and mouthparts. These structures are the insect's most important sense organs.

Eyes. Moths have two large *compound eyes* on each side of the head. These eyes consist of many separate lenses, each of which supplies an image of part of the moth's surroundings. Compound eyes are specially designed to help an insect spot movements, such as the approach of an enemy.

Antennae. Two antennae stick out from between a moth's eyes. Moths use antennae chiefly to smell. Antennae are very sensitive to chemicals in the air. Female moths release chemicals called *pheromones* into the air to attract males for mating. The antennae of a male moth can "smell" a female as far as 5 miles (8 kilometers) away.

Mouthparts. Adult moths feed mostly on liquids, such as flower nectar and the juice of fruits. They suck up their food through a long, hollow tongue called a *proboscis.* The proboscis coils under the head when not in use. Some adult moths lack mouthparts. These adults live only a few days and do not feed.

The thorax forms the middle section of a moth's body. It consists mostly of the muscles that power the wings and legs of the insect. The moth's wings and legs are attached to the thorax.

Legs. Adult moths have three pairs of legs. Each leg consists of five segments. Joints connect the segments. Taste organs develop on the tips of the legs.

Wings. Two membranes form each of a moth's wings. A network of hollow tubes called *veins* supports the wings. Tiny scales cover the membranes and give the wings their colors and patterns. The females of some species lack wings and cannot fly.

The abdomen contains the organs of reproduction and the major organs of digestion. Tiny holes called *spiracles* on the sides of the abdomen and thorax lead into the insect's respiratory system. Spiracles enable oxy-

gen to enter the moth's body and carbon dioxide to leave the body.

The life cycle of moths

Every moth goes through four stages of development: (1) egg, (2) larva, (3) pupa, and (4) adult. This process is called *metamorphosis.*

The egg. Female moths lay their eggs one at a time or in masses, usually in summer or fall. A female moth may lay from a few to more than 18,000 eggs. Most moth eggs measure less than $\frac{1}{25}$ inch (1 millimeter) across and are round or oval. Often, the female deposits the eggs on the kinds of plants that her offspring like to eat. The eggs of most species hatch within a week. The eggs of some species do not hatch until spring.

The larva, or caterpillar, that crawls out of the egg is made up of 14 segments, including a head. Caterpillars have three pairs of legs near the front of the body. Most caterpillars also have five pairs of leglike *prolegs,* farther back on the body. Many moth caterpillars are extremely colorful. Some have fierce-looking spines or bristles.

Caterpillars have chewing mouthparts. Moth caterpillars chiefly eat leaves and other plant parts. They may also feed on wood, the larvae of other insects, and hair. One group of moths, the clothes moths, feed on clothing and other materials made of wool, the hair of sheep.

A short structure called the *spinneret* sticks out below the mouth. The caterpillar sends out an almost continuous stream of liquid silk through the spinneret. The silk quickly hardens to a slender thread that gives the caterpillar a foothold as it crawls about. This thread can also prevent the caterpillar from falling to the ground if the insect slips off a plant.

Caterpillars reach full size from within a month to several months or years, depending on the species and other factors. Like other insects, they shed their skin several times as they grow. This process is called *molting.*

The pupa. The final molt transforms the caterpillar into a *pupa,* an inactive stage during which dramatic physical changes occur. The caterpillar may spin a protective, silken cocoon around itself for the pupal stage. The insect fastens the cocoon to a tree limb or some other solid object. Inside the cocoon, the insect forms a protective covering of a substance called *chitin.* Some moth caterpillars do not spin cocoons. Instead, they burrow into the ground or hide under loose bark before forming a chitin shell.

During the pupal stage, the insect changes into an adult moth. This change, called *pupation,* takes a few days or several months, depending on the species.

The adult. At the end of pupation, the adult moth breaks out of its pupal covering. If the moth has wings, blood quickly pumps into the wings and expands their size. Soon the moth flutters off in search of food or a mate. Most adult moths live only a few days to a few weeks, but some may survive six months or more.

Migration

Many moths need warm air temperatures for their flight muscles to work. Large moths must "heat up" their flight muscles before flying by rapidly vibrating their wings.

Some moths avoid cold weather by migrating to warmer regions. For example, a hawk moth migrates from the United Kingdom and Ireland to southern Europe in the fall. Moths may also migrate to avoid other unfavorable conditions. Bogong moths of Australia migrate from lowland pastures to the mountains during the summer to avoid extreme heat. In the mountains, where food is scarce, these moths enter a resting state called *diapause* to save their energy. In the fall, they again become active and return to the lowlands to mate.

Cary Wolinsky, Stock, Boston

Colorful cocoons of the *Bombyx mori* moth fill a silk grower's frame. Silk is obtained by unraveling the cocoons. Caterpillars of the moth are shown crawling across the frame.

Norman Owen Tomalin, Bruce Coleman Inc.

The gypsy moth caterpillar is a serious forest pest. Each year, gypsy moth caterpillars defoliate vast areas of forestland in eastern North America by stripping trees of their leaves.

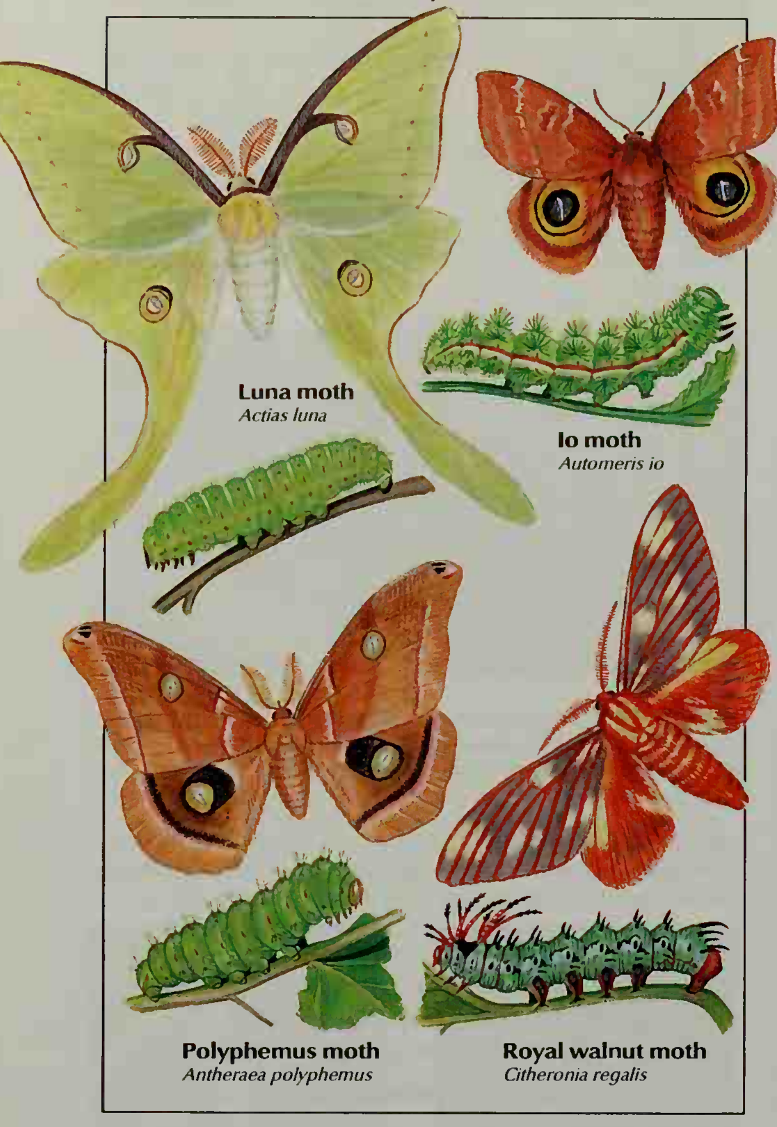
Defenses against enemies

Moths have many enemies. For example, certain wasps lay their eggs on or inside moth caterpillars. The wasp larvae feed on the body fluids of the caterpillar and eventually kill it. Other animals prey on adult moths. These predators include spiders, birds, and bats.

Moths have developed various ways of protecting themselves against predators. By flying primarily at night, moths avoid many daytime predators. Many moths have coloring that blends with their surroundings. For example, certain moths look like the bark or leaves of a tree. Some moths have markings on their underwings that resemble the eyes of a larger animal. These eyespots are shown when the moth is attacked, and they may frighten away predators.

Some moth caterpillars are bad-tasting or even poisonous to predators. Such insects may have vivid markings. An animal that eats one of these caterpillars will most likely avoid eating another one marked similarly.

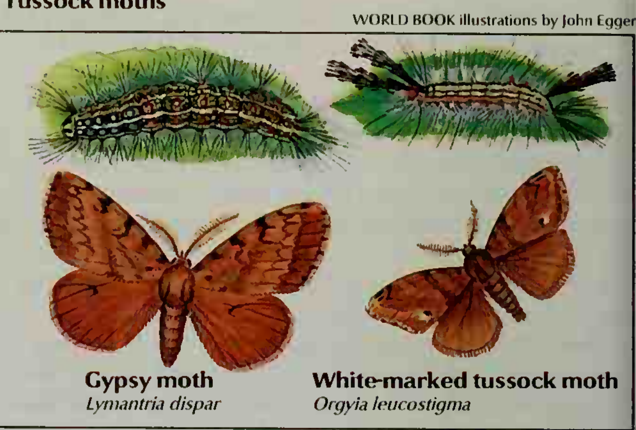
The importance of moths



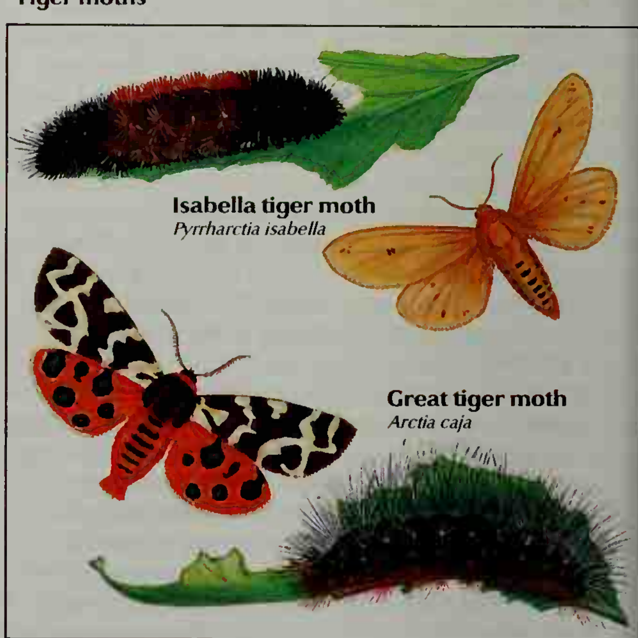
The best-known benefit of moths to human beings is probably the production of silk. In China, people have

Some North American moths

There are more than 100,000 species of moths worldwide. These drawings show members of si of the largest moth families. All the moths shown live in North America. The caterpillar of each species is also illustrated. The scientific name of the species appears in italics.



Giant silkworm moths and royal moths



Tussock moths

WORLD BOOK illustrations by John Egger

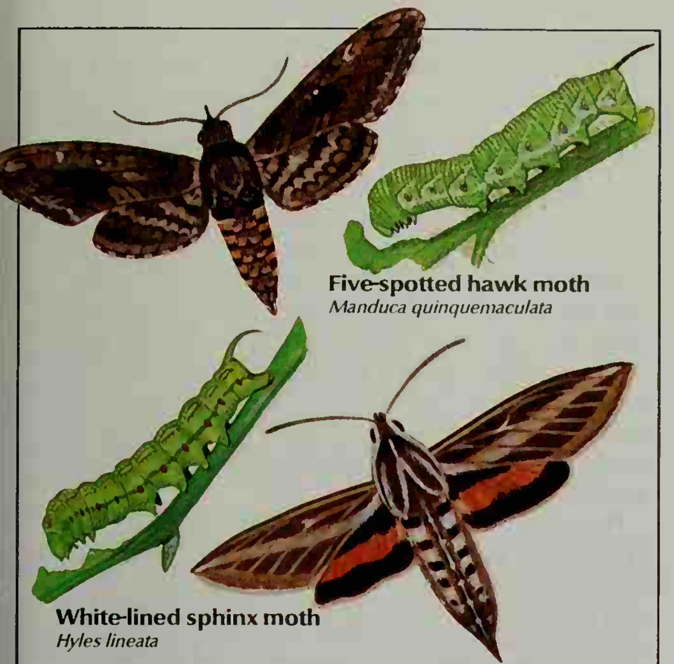
Tiger moths

used a species of moths called *Bombyx mori* to produce silk for more than 4,000 years. To obtain the silk, workers unravel the moth's cocoon into a single, long thread. The thread is then combined with thread from other cocoons and woven into silk fabrics.

Moths are important in the pollination of certain flowers. Pollination occurs when a moth visits flowers to feed on nectar. Grains of pollen stick to the moth's body as it feeds and then rub off on other flowers the insect visits. Some flowers that bloom only at night depend on night-flying moths for pollination. Most flowers pollinated by moths are white, have long tubelike petals, and produce a strong scent.

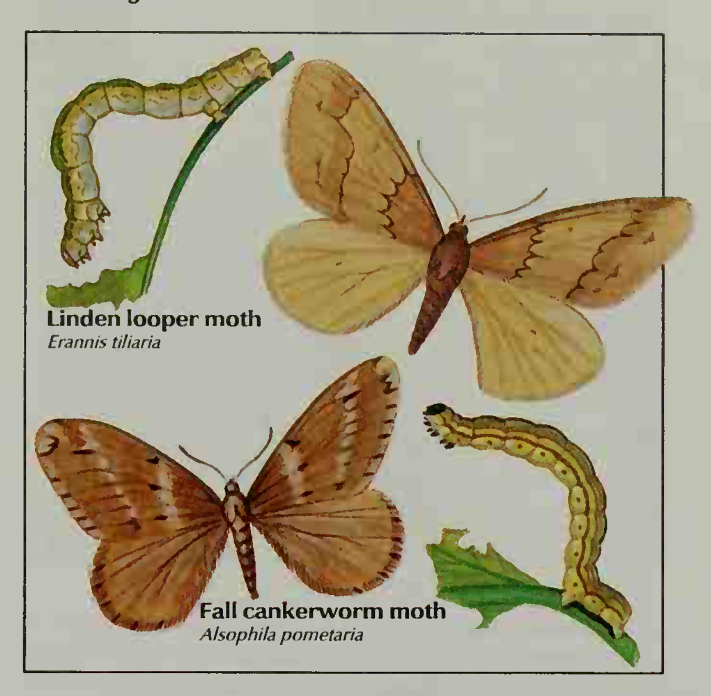
Moth caterpillars cause extensive damage to crops and forests each year. Some species feed on woolen fabrics and other animal products.

Kinds of moths



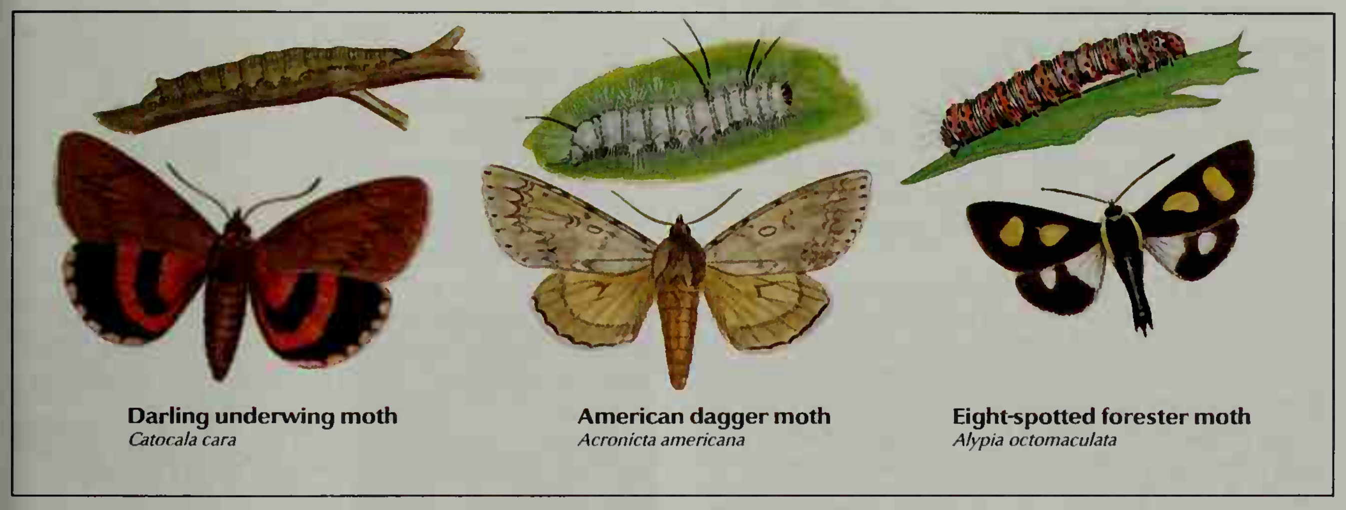
There are more than 100,000 species of moths. They are grouped into various families, according to common physical features. This section describes six of the most common families of moths. The scientific name of the family is given in parentheses after the common name.

Owlet moths and underwing moths (Noctuidae) total more than 20,000 species and form the largest family of moths. Most of these moths are small to medium in size. The majority of species are dull-colored, but many underwing moths have bands of bright colors on the hind wings.



Both owlets and underwings have a pair of special hearing organs called *tympani* on the thorax. These organs can pick up high-frequency sounds made by bats. Upon hearing a bat, these moths may fly in an irregular pattern or dive to the ground to avoid being eaten. Many caterpillars in this family, including cutworms an army worms, cause serious damage to crops.

Tiger moths (Arctiidae) consist of about 10,000 species. They are small to medium in size. Many have brightly colored patterns on their wings. Many caterpillars in this family also have bright coloring and may be



Hawk moths (sphinx moths)

Measuringworm moths

Owlet moths and underwing moths

covered with a dense hairlike mat. A common caterpillar of this type is the *woollybear caterpillar.* It grows into the Isabella tiger moth. Tiger moth caterpillars feed on plants, including poisonous ones. The poison stays in the moths into adulthood and helps protect them from animals that might otherwise eat them.

Measuringworm moths (Geometridae) make up about 12,000 species. Most are small with relatively large wings. The females of several species have no wings.

The caterpillars in this family are commonly called *measuring worms* or *inchworms* because of their unusual crawl. They crawl by alternately looping their bodies into the air and then extending their front legs to straighten themselves. Some inchworms, such as cankerworms, seriously damage trees. Several species of inchworms that live in Hawaii can catch and eat flies.

Tussock moths (Lymantriidae) number about 2,000 species. Adult tussocks do not have working mouthparts and so they cannot feed. They live only a few days or weeks. These medium-sized moths typically have dull coloring. The females of some species rarely fly. In other species, the females have no wings at all.

The caterpillars of tussock moths generally have long, hairlike tufts called *tussocks* on their backs. In some species, these tussocks cause skin irritation if touched. Many tussock caterpillars are serious pests of North American forests. One well-known species, the caterpillar of the gypsy moth, defoliates vast areas of eastern forestland each year by eating leaves.

Hawk moths (Sphingidae), also called *sphinx moths,* total about 1,000 species. Many of them have bright coloring. Hawk moths are swift flyers and beat their wings so rapidly that they are often mistaken for hummingbirds. Some species of hawk moths resemble bumble bees or wasps. Hawk moth caterpillars have a curved, hornlike structure near the end of the abdomen. For this reason, they are often called *hornworms.*

Giant silkworm moths and royal moths (Saturniidae) consist of about 1,300 species. In general, the members of this family are brightly colored and have dark or transparent eyespots on the hind wings. Some

species, including the luna moth and the giant Hercules moth, have a long, taillike extension on each hind wing. Giant silkworm moths and royal moths do not feed, and thus they live only a few days.

The caterpillars of many silkworm moths and royal moths have stiff bristles on their bodies. In some species, the tips of the bristles contain irritating chemicals. Many caterpillars in this family feed on trees and shrubs. The cocoons of several Asian species produce a coarse silk known as *tussah silk.* But the species most commonly used in the production of commercial silk belongs to another family. Bernd Heinrich

Mother Goose is a name that has been associated with children's literature for hundreds of years. Mother Goose appears as the author of countless collections of tales and rhymes in many languages. However, no one knows if an actual Mother Goose ever existed. Some scholars believe that Mother Goose is based on a real person, but others say that Mother Goose is a fictional character.

Who was Mother Goose? Scholars who believe Mother Goose actually existed have several theories about her identity. According to one theory, she was the Queen of Sheba, who lived in Biblical times. Others suggest she was Queen Bertha, the mother of the great medieval military leader Charlemagne. Queen Bertha, who died in 783, was nicknamed "Queen Goose-Foot" or "Goose-Footed Bertha."

Another theory proposes that the original Mother Goose was a woman named Elizabeth Goose (or Vergoose or Vertigoose), who lived in colonial Boston. The woman enjoyed entertaining her grandchildren with the songs and rhymes she remembered from her own childhood. Her son-in-law, Thomas Fleet, supposedly collected those songs and rhymes and published them in 1719 as *Songs for the Nursery, or Mother Goose's Melodies.* However, no copy of this book has ever been found, and most scholars doubt that the book ever existed.

Some Mother Goose books pictured her as an old woman with a crooked nose and large chin, usually telling stories to a group of children. Other editions have pictured Mother Goose as an old woman with a tall hat and a magic wand, riding through the air on the back of a goose.

The history of Mother Goose literature. Most of the rhymes and verses that appear in Mother Goose books existed long before they were published. Many of them originated in England and were based on folk songs, ballads, street cries, and tavern songs. A number included humorous or satirical verses that were based on real people, events, or customs. These early rhymes were written to entertain adults. Before 1800, the only rhymes that were written for small children were alphabet rhymes, lullabies, and verses that accompanied games.

Mother Goose was popular in France as early as the mid-1600's, when the name was attached to collections of tales. In 1697, Charles Perrault, a French writer, published a book called *Histories or Tales of Past Times, with Morals.* The front of the book had an engraving of an old woman sitting by a fireplace, apparently telling stories to three listeners. A sign on the wall read, "Contes de Ma Mère L'Oye" ("Tales of Mother Goose"). Perrault's collection popularized eight tales that may have been known at the time, including "Sleeping Beauty," "Red Riding Hood," and "Cinderella."

Perrault's book was translated into English by Robert Samber and published in England in 1729. An engraving of an old woman was included in this edition, with a sign on the wall reading "Mother Goose's Tales." The name was adopted for the title when the tales were reissued in 1768 by the John Newbery publishing house. The same publishers issued a collection of rhymes in 1781, which they called *Mother Goose's Melody.* "Ding Dong, Bell" and "Little Tom Tucker" were among its 51 rhymes. The book also contained 16 songs from plays written by William Shakespeare. *Mother Goose's Melody* was reprinted several times in England.

The first Mother Goose book published in America was a reprint of Newbery's *Mother Goose's Melody,* issued by Isaiah Thomas in 1786. The Boston publishing firm of Munroe and Francis published *Mother Goose's Quarto, or Melodies Complete* about 1825. It was reprinted in 1833 as *The Only True Mother Goose Melodies* and consisted of 169 rhymes, including an 11-verse version of "London Bridge." Since the early 1800's, the name of Mother Goose has been firmly associated with collections of rhymes. Marilyn Fain Apseloff

Mother-of-pearl. Certain shellfish, such as pearl oysters, abalones, and freshwater mussels, produce shells lined with a lustrous, rainbow-colored material. This material is called *mother-of-pearl,* or *nacre* (pronounced *NAY kuhr*). It varies in color from pale grayish-blue and pink to purple and green. Shells containing mother-of-pearl are found off the coasts of tropical countries, particularly around the South Sea Islands, the Philippine Islands, Australia, Panama, and Lower California.

Mother-of-pearl has long been commercially valuable. It has been used for ornamentation, in the manufacture of buttons, and in the inlay for various works of art, particularly those made of wood and silver. People

of many island cultures have bartered mother-of-pearl for other goods. Today, mother-of-pearl is commonly used in making jewelry, such as pearl necklaces, and for decorative pocketknife handles. John S. Lizzadro

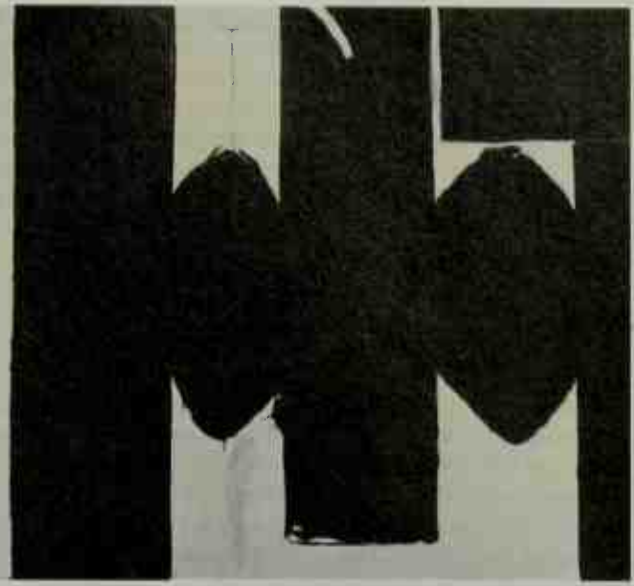
Mother's Day is set apart every year in honor of motherhood. On the second Sunday in May, many families and churches make a special point of honoring mothers. Many people follow the custom of wearing a carnation on Mother's Day. A colored carnation means that a person's mother is living. A white carnation indicates that a person's mother is dead.

A day for honoring mothers was observed many years ago in England. It was called *Mothering Sunday* and came in mid-Lent. People in other European nations have observed similar days.

Julia Ward Howe made the first known suggestion for a Mother's Day in the United States in 1872. She suggested that people observe a Mother's Day on June 2 as a day dedicated to peace. For several years, she held an annual Mother's Day meeting in Boston. Mary Towles Sasseen, a Kentucky schoolteacher, started conducting Mother's Day celebrations in 1887. Frank E. Hering of South Bend, Indiana, launched a campaign for the observance of Mother's Day in 1904.

Three years later, Anna Jarvis of Grafton, West Virginia, and Philadelphia began a campaign for a nationwide observance of Mother's Day. She chose the second Sunday in May and began the custom of wearing a carnation. On May 10, 1908, churches in Grafton and Philadelphia held Mother's Day celebrations. The service at Andrews Methodist Episcopal Church in Grafton honored the memory of Anna Jarvis's own mother, Anna Reeves Jarvis.

United Press Int.



Anna Jarvis

At the General Conference of the Methodist Episcopal Church in Minneapolis, Minnesota, in 1912, a delegate from Andrews Church introduced a resolution recognizing Anna Jarvis as the founder of Mother's Day. It suggested that the second Sunday in May be observed as Mother's Day.

Mother's Day received national recognition on May 9, 1914. On that day, President Woodrow Wilson signed a joint resolution of Congress recommending that Congress and the executive departments of the federal government observe Mother's Day. The next year, President Wilson was authorized to proclaim Mother's Day an annual national observance. Sharron G. Uhler

Motherwell, Robert (1915-1991), an American painter, was a leading member of the Abstract Expressionist school. Motherwell became famous for several series of paintings. But his large body of work includes many widely varied themes ranging from violent and large menacing shapes to tender, intimate forms.

Motherwell began his best-known series, *Elegies to the Spanish Republic,* in 1948 and continued it through the 1970's. This group of more than 100 paintings deals with his emotional reaction to the Spanish Civil War (1936-1939). Motherwell used colors and designs that suggest characteristics of Spain's landscape. In the mid-1950's, he created the *Je t'aime* series, which features broad, freely applied brushstrokes. During the 1940's and 1950's, Motherwell also produced collages. In the early 1960's, he painted a series called *Beside the Sea.* These works have simple shapes and sharp color combinations that represent the sea and splashing waves.

Elegy to the Spanish Republic LV (1960), an oil painting on canvas; Contemporary Collection of the Cleveland Museum of Art

A Motherwell painting is part of the artist's series called *Elegies to the Spanish Republic.* Most of these paintings consist of black oval between vertical panels on a light background.

Motherwell was born on Jan. 24, 1915, in Aberdeen, Washington. He worked in many techniques, including etchings, lithographs, and illustrated books. Motherwell also wrote essays on art and edited a series of books by modern artists. He died on July 16, 1991. *The Collected Writings of Robert Motherwell* was published in 1993, after his death. Dore Ashton

See also **Abstract expressionism.**

Motion. See **Parliamentary procedure** (Motions).

Motion occurs when an object changes its location in space. *Motion* is a relative rather than an absolute term. An object may be in motion with regard to another object, but may be stationary with respect to a third object. For example, suppose you are riding on a train and you pass a person standing alongside the tracks. The person standing along the tracks will see you and everyone else on the train as in motion. But the person sitting next to you on the train will be stationary with respect to you.

Everything in the universe is in motion. Even as you sit reading this page, you are moving very rapidly because the earth is rotating on its axis. You are also moving with the earth as it revolves around the sun. In addition, the sun, the earth, and the rest of the planets in our solar system are involved in the general rotation of our galaxy within the universe.

The difference in motion between yourself and the object that you are looking at is called *apparent motion.* For example, suppose you are riding in a car on the

highway and another car is moving slightly faster than yours. You will see the other car as being in a small apparent motion relative to your car. Your car becomes your *frame of reference.*

There are two important forms of motion. One is called *rectilinear motion,* in which objects move in straight lines. This motion normally occurs when objects are moving freely. Motion along a curved path is called *curvilinear motion.* In curvilinear motion, objects are pushed sideways by a force.

Qualities of motion

Velocity. The rate of motion is usually referred to as *speed.* The term *velocity* describes both the speed of an object and its direction. When a car moves along a curve and the speedometer does not change, the car is said to be moving at a constant speed. But the car's velocity is changing because its direction of motion is changing. Both speed and velocity can be expressed in various units of measurement that describe how far an object travels in a period of time. These units include miles per hour, feet per second, and centimeters per second. When both the speed and direction of an object are constant, the motion of the object is said to be *uniform.*

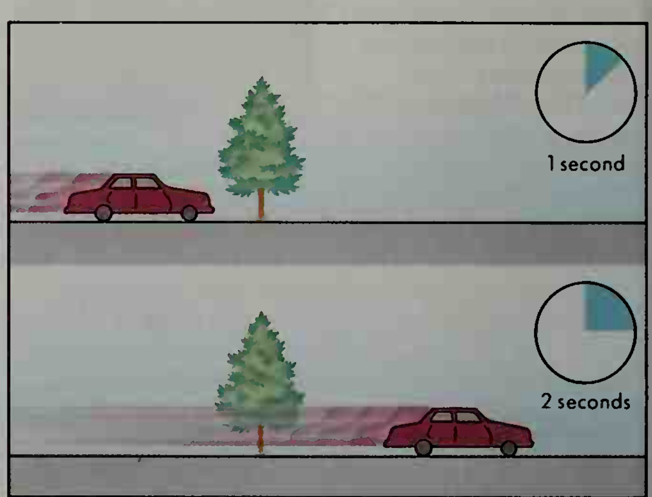
Acceleration occurs whenever the velocity of an object changes. Acceleration is how much the velocity has changed in a period of time. It is expressed in such terms as miles per hour per second, kilometers per hour per second, and feet per second per second. For example, if a car traveling 3 miles per hour in its first second travels 6 miles per hour in its second second and 9 miles per hour in the third second, it is said to have a uniform acceleration of 3 miles per hour per second. The velocity of the car has increased 3 miles per hour for each second of motion.

A decrease of the velocity of an object over time is called *negative acceleration* or *deceleration.* For example, when a car brakes while approaching a stop sign, it decelerates. Both acceleration and deceleration can be *variable* (changeable) as well as uniform.

One situation where uniform acceleration occurs is when a ball is rolled down an inclined plane. The uniform acceleration of the ball will be twice the distance the ball rolls during its first second of movement. For example, a ball that rolls 1 foot in the first second has an acceleration of 2 feet per second per second. The distance the ball will have traveled and the velocity it will have reached after an interval of time can also be determined. The distance can be found using the formula $S = \frac{1}{2} at^2$, where S is the distance, a is the acceleration, and t is the time elapsed. The velocity (v) can be found with the formula $v = at$. Therefore, if a ball has a uniform acceleration of 2 feet per second per second, after 2 seconds it will have traveled 4 feet and its velocity will be 4 feet per second.

Similarly, if a car accelerates at a constant rate of 10 feet per second per second, after 5 seconds its velocity will be 50 feet per second, and it will have traveled 125 feet. After 10 seconds, the car's velocity will be 100 feet per second, and it will have traveled 500 feet.

Uniform acceleration also occurs when an object falls freely through the air. In this case, gravity provides a constant acceleration of 32 feet per second per second (9.8 meters per second per second). For example, a ball falling under gravity will have traveled 16 feet (4.9 meters) in 1 second and 64 feet (19.6 meters) in 2 seconds. But objects do not actually fall quite this fast because of the resistance of the air. In formulas where gravitational acceleration applies, the symbol g—for gravity—replaces a.



Momentum and kinetic energy. The momentum *(p)* of a moving object equals its mass *(m)* multiplied by its velocity *(v)*; $p = mv$. An object with momentum also has kinetic energy. This energy, which is often called the *energy of motion,* is the energy a body possesses because of its motion. The kinetic energy *(E)* of an object is one-half of its mass multiplied by the square of its velocity. The formula is written $E = \frac{1}{2} mv^2$. When the formula is written in terms of the momentum of the object, it is $E = \frac{1}{2} pv$.

The kinetic energy of an object increases with the square of its velocity. For example, an automobile moving at 60 miles an hour has four times the energy it would have at 30 miles an hour. This increase in kinetic energy is why high-speed collisions are so much more dangerous and damaging than low-speed collisions. When a moving object collides with another object, energy and momentum are transferred. The energy given up by the moving object is called the *impact.* Objects moving at high velocity have high impact if they strike another object.

Objects obtain momentum and kinetic energy from forces acting on them for a period of time. The longer the time of action, the larger the momentum and kinetic energy. In such sports as tennis and golf, players follow through with their rackets and clubs so that force is applied to the ball for the longest time possible. As a result, the ball travels faster and has greater momentum and kinetic energy.

How friction affects motion

If we roll a ball along the ground, we notice that it slows down and stops even though no apparent force is being applied to it. The ball slows down and stops because of *friction.* Friction is resistance to motion. Air is

WORLD BOOK illustration by Sarah Woodward

Motion can be described in terms of speed, which measures how far an object travels in a certain length of time. If the car above moves at a speed of 50 feet (15 meters) per second, in 2 seconds it will have traveled 100 feet (30 meters).

one of the most common causes of friction. Automobiles and airplanes are streamlined to make them move more easily through the air.

But friction is also a help. Without it people could not walk on the earth. Instead, they would slide. We would not be able to nail two boards or screw metal objects together because friction holds them in place. When we apply the brakes on a car or a bicycle, it is friction that slows down the wheels.

In many instances, we try to reduce friction by making the surfaces of objects move more easily over one another. Smoothing out surfaces or placing another substance, such as a lubricating oil, between two solid surfaces reduces friction. Rotating objects such as roller bearings, ball bearings, and wheels may also greatly reduce friction. They make it easier to push such large, heavy objects as beds or automobiles.

Newton's laws of motion

In the 1600's, the English scientist, astronomer, and mathematician Isaac Newton proposed three laws of motion. Newton's laws concern the ideal motion of objects and do not take into account air resistance or other friction. However, these laws have enabled scientists to describe a wide variety of motions.

The first law states that an object moving in a straight line will keep moving in a straight line unless it is acted upon by an outside force. This law also states that an object at rest will stay at rest unless a force moves it. Newton's first law is known as the *principle of inertia.* Inertia is the property of matter that makes an object stay in motion if it is moving or remain motionless if it is not moving. Forces that change an object's motion must first overcome the object's inertia. The greater an object's mass, the harder it is to put the object into motion or change its velocity. Inertia serves as a measurement of how hard it is to get an object moving. See **Inertia.**

The second law describes how an object changes its motion when a force is applied to it. The change of motion depends on the magnitude of the force and the mass of the object. A heavier object will change its motion less under a given applied force than will an object of lighter weight. Therefore, if the same force is applied to two objects, the change of motion of the lighter-weight object will be greater. Newton's second law also states that the effect of a given force is always in the direction of the force. For example, if an object is pushed toward the west, it moves that way and not toward the east. Newton's second law may be written as $F=ma$, where F is the applied force, m is the mass, and a is the acceleration. Scientists use this formula to describe motion of all kinds of objects.

According to Newton's second law, forces cause changes in the motion of objects. Suppose a person fires a bullet horizontally from the muzzle of a gun. Newton's first law says that the bullet will continue to travel in a straight line forever if no forces act upon it. However, the earth's gravity does act on the bullet. As a result, the bullet will fall toward the ground. This fall occurs because the force of gravity pulls the bullet downward at right angles to the direction of travel.

If the rifle is fired horizontally from a height above the earth of 16 feet (4.9 meters), the bullet will be accelerated by gravity and hit the ground in one second—the same time it would take a freely falling body to drop. Because of gravity, rifles or any other type of gun have a limited range of distance they can shoot. In addition, bullets must be shot slightly upward to increase the range and make up for the drop.

The third law of motion states that for each action there is an equal and opposite reaction. For example, when hot gases escape from a rocket engine during take-off, the rocket is propelled upward. The downward motion of the gases from the rocket generates a reaction of the rocket upward. This reaction helps the rocket overcome air resistance and fly into space. There are many other examples of Newton's third law. When a rifle fires a bullet, the firing of the bullet is the action and the recoil of the rifle is the reaction. Both are caused by the expanding gas of the exploding gunpowder. Rotating lawn sprinklers propel a spray of water in one direction while rotating in the other direction.

Sometimes the reaction is such that it cannot be easily seen. When you throw a ball against a wall and the ball bounces back, you do not see the wall moving in the opposite direction. But there is a small motion of the area of the wall that was hit. If the ball bounces from the ground, the earth also draws back, but the mass of the earth is so great that we cannot see its motion.

Modifications of Newton's laws, particularly his second law, were proposed in the early 1900's by the German-born physicist Albert Einstein. For example, Einstein concluded that, based on his own *special theory of relativity,* the mass of an object can change with its velocity. But this effect is only important at velocities that are near that of the speed of light, which is 186,282 miles (299,792 kilometers) per second. See **Relativity.**

Motion, Andrew (1952-), was appointed poet laureate of the United Kingdom in 1999. He succeeded Ted Hughes, who died in 1998. Motion's poetry has been praised for its economy of style and elegant, unsentimental tone.

Motion often uses legendary and historical figures in his works, which include long prose-poems as well as shorter verse. He writes on personal issues as well as social and political themes. His first volume of poetry was *The Pleasure Steamers* (1978), which includes a long historical poem called "Inland" set in the 1600's. His volume *Natural Causes* (1987) contains a poem about Philip Larkin, the English poet whose work influenced Motion's poetry. *Salt Water* (1997) includes a poem that describes Motion's re-enactment of a sea journey made by the poet John Keats.

Motion has written several highly praised biographies, including *A Writer's Life* (1993) about Philip Larkin. He also wrote the novels *The Pale Companion* (1989) and *Famous for the Creatures* (1991). Motion was born in London. D. E. White

Motion pictures provide entertainment for millions of people throughout the world every day. The musical fantasy *The Wizard of Oz, shown here,* has been an audience favorite since its release in 1939. Judy Garland, its young heroine, became one of the most popular stars in movie history.

Motion picture

Motion picture is a series of images recorded on film or tape that appear to move when played through a film projector or a video entertainment system. Also known as movies, film, or cinema, motion pictures are one of the most popular forms of art and entertainment throughout the world. They are also a major source of information.

Every week, millions of people go to the movies. Many millions more watch movies that are broadcast on television or played on a videocassette, videodisc, compact disc, or DVD player.

But movies are much more than just entertainment. The motion picture is a major art form, as are, for example, painting and drama. Artists express themselves by using paint and dramatists by using words. Filmmakers express their ideas through a motion-picture camera. By using the camera in different ways, the filmmaker can express different points of view. A filmmaker may film scenes in a desert, on a mountain, and in a large city. Filmmakers can also film scenes from different angles. Later, through a process called *editing,* they can select the angle that most effectively expresses a dramatic point. Through editing, the filmmakers can also show events happening at the same time in different places.

Movies have become a gigantic industry. A typical feature-length film costs millions of dollars to make and requires the skills of hundreds of workers. Highly technical devices, including cameras, sound-recording equipment, and projectors, are needed to film and show movies. In fact, motion pictures could not exist without many of the scientific and technical discoveries made since the late 1800's. For this reason, movies have been called the art form of the 20th century.

We can enjoy many forms of art and entertainment by ourselves. We can enjoy reading a story or looking at a painting alone. But films are intended to be viewed in theaters. As a result, we usually enjoy a motion picture the most when we watch it as part of a large audience. Although many people watch movies at home on television or a video entertainment system, most films deliver their strongest impact on viewers in theaters.

The movies have a brief history, compared to such art forms as music and painting. Movies date back only to the late 1800's. By the early 1900's, filmmakers had developed distinctive artistic theories and techniques. Motion pictures received little scholarly attention, however, until the 1960's. Since then, thousands of books have been published about every aspect of filmmaking and film history. Many universities and colleges offer degrees in motion pictures, and many more offer film courses.

Movies have many uses in education, especially as teaching aids, in addition to their artistic and entertainment values. Teachers use such films in classes on ge-

ilent movies established the power of film. Silent stars, such as Charlie Chaplin, *left,* gained vorldwide fame. The 1925 Soviet classic *The Battleship Potemkin, right,* showed how film could be ised as propaganda. It featured this scene of civilians being massacred by their government.

ography, history, mathematics, and the physical and so- ial sciences. Movies use slow motion, animation, and other special techniques to demonstrate processes that otherwise could not be seen or studied thoroughly. For example, a film can show the formation of crystals at fast peed so a class can study this process.

Television stations use motion pictures to inform as vell as to entertain their viewers. TV stations frequently present *documentaries.* A documentary is a nonfiction novie that tries to present factual information in a dra- natic and entertaining way. Documentaries deal with a ariety of subjects, such as environmental pollution and he history of presidential elections. Made-for-TV mov- es may deal with sensitive social issues within the ramework of a regular entertainment movie.

Millions of people enjoy taking their own motion pic- ures with small motion-picture cameras or with video ameras, also known as *camcorders.* Home movies began to develop as a hobby during the 1920's, follow- ng the invention of low-cost film that could be used in mall cameras. The popularity of home movies has in- reased over the years with the improvement in cam- eras and projectors, the introduction of color and sound ilm, and the development of home video recorders that play back on TV sets.

This article deals mainly with feature-length motion pictures made for exhibition in theaters and on video- cassettes and television. For information on equipment ised in making home movies, see the articles on **Cam- corder** and **Videotape recorder.**

Shooting the movie is actually one of the later stages in making a motion picture. First comes a great deal of planning and development. This movie is being shot on a *sound stage*—a large soundproof building especially designed for filmmaking.

Making a feature film calls for a special blend of art and business skills. A motion picture may take less than six months to more than two years to create. The film can cost less than $250,000 or more than $100 million. A big-budget film will employ several hundred people.

Although the film cast and crew may include hundreds of members, the people who perform two key functions remain at the center of the filmmaking process: the *producers* and the *director.* The producers are the chief business and legal managers of the film. Usually, one or more *executive producers* from the film company supervise the work of the producer of the specific motion picture. By choosing the director and other key members of the creative team, and by supervising the budget, the producers exert great influence over the creative part of the film production.

The director is responsible for guiding the creative efforts of the screenwriters, cast, and crew. By influencing the film's shooting schedule and the equipment and personnel needs of the film, the director plays a major role in shaping the budget.

Each film presents a different set of problems for the producers and director. Some movies call for extensive traveling to distant locations. Others call for complicated special effects. Some need elaborate sets or an intimate and delicate acting style. Regardless of the particular challenges, each film will pass through five stages to reach its audience. These stages occasionally overlap, but they occur in the following order: (1) development, (2) preproduction, (3) production, (4) post-production, and (5) distribution. This section describes the first four stages. The fifth stage—distribution—is discussed in the section *The motion-picture industry.*

Before the late 1940's, almost all American motion pictures were produced by major studios in or near Hollywood, California. Today, most movies are made by independent film producers. The following section describes chiefly how a motion picture is made by an independent producer. The key personnel and many of the steps also apply to films made by the major studios. For information on the "studio era," see the *History* section of this article.

Development

Developing the story. All feature films begin with an idea for a story. The idea can come from a newspaper article, from someone's imagination, or from an existing book or play. The idea may be as complicated as a 30-page outline or as simple as a single sentence. No one person is responsible for finding an interesting source for a film story. Movie ideas come from screenwriters, producers, directors, actors and actresses, agents, and friends of the filmmaker.

After a good idea has been identified, the producer or director must find a screenwriter with the ability and sensitivity to turn that idea into a story that will work as a movie. Once commissioned, the screenwriter works closely with the project's originator to develop the characters and to construct the story based on the original idea. The screenwriter's job is to create the document that will serve as the blueprint for producing the film. This document is the *screenplay.*

WORLD BOOK photo by John Hamilton, Globe Photos

The script contains the dialogue, a description of the action, and the camera angles for each scene. The script supervisor records the director's instructions on the script, *above.*

When looking for a *property* (story) to film, producers also review scripts prepared by screenwriters working on "spec." "Spec" means that the screenwriter has not been contracted—or even informally asked—to write a script based on someone else's idea. Instead, the writer is speculating that his or her own idea will be sold to a producer or studio.

A writer working on spec sends an original script to an agent who will market it. The agent shows the script to producers and studio executives who may be interested in purchasing and producing it. If they are interested, they can purchase the script outright or—for a reduced fee—they can *option* it. By taking an option on a script, producers acquire the exclusive rights to the script for a limited time. During that time, they explore the possibility of producing the script. If they decide to produce it, they then buy the script. If they want more time to decide, they can renew the option. If the option is not renewed, the screenwriter keeps the option fee and has the right to sell the script to another producer.

Acquiring financing. After obtaining a property, most independent producers must secure financial backing for the project. As a first step, they usually try to interest a successful director or a recognized actor or actress in the film. Associating a proven director or star with the project helps assure investors that the movie will have box-office appeal. Choosing the director and leading performer is one of the most important steps in the production of a film—not only because it helps in obtaining financing, but also because each star-director-producer team will interpret a script differently.

In another major step before approaching potential investors, the producers prepare an estimated budget and a shooting schedule. They consider the expected size of the film's audience, the amount of money realistically required to create the film, and the amount of money they can expect to raise from investors.

After the producers are satisfied with the estimated budget and shooting schedule, they put together the film's "package." The package consists of the budget, script, shooting schedule, and key creative people who will make the film. Based on the package, the producers seek funds from banks, studios, or private investors. The money will be raised if the creative team's experience and "name recognition" value are strong and the budget seems low enough for the film to make a profit. In some cases, the package will be so strong that the producers will also be able to sell the project to a distributor at this stage. Once the funds are secured, the actual planning of the production can begin.

Preproduction

During the preproduction stage, the producers, the director, and other key crew members create a detailed plan of action for turning the script into a motion picture. This involves planning for all the creative decisions, personnel choices, equipment, and material necessary to make the film. The goal is to anticipate and solve all problems likely to be encountered in producing the motion picture.

The preproduction period can take as little as two

weeks to six months or more. By the end of this period, the crew is a well-organized group with a common goal. They understand the deadlines they face to complete the film, and they have all the major materials ready so they can execute their plan smoothly.

The preproduction period is the beginning of intense collaboration among the members of the production team. At the center of these collaborations are the producers and the director. They develop and carry to the members of the crew their overall vision of the film. Through a series of meetings and discussions with the cast and crew, they decide upon the specific interpretations of the look and sound of the script.

Reviewing the script. All phases of preproduction start with a careful reading and analysis of the script. The director examines the script to understand the story and to develop a vision of the most effective way to translate the script into film and sound images. Suggestions from members of the creative team often lead to further revisions of the script. The director also develops ideas on casting, costuming, set design, photography, and editing.

Assembling the production team. Working closely with the producers, the director hires a crew. The director will try to choose craftworkers who, because of their experience and understanding of filmmaking, will develop and enhance the director's idea of the film.

The production manager is one of the key positions in the team. The production manager develops the actual budget and shooting schedule. Working under the producers, the production manager will supervise the production and authorize all expenditures.

The director of photography, or *cinematographer,* is responsible to the director for achieving the best possible visual look for the film. The director of photography supervises the camera crew, and designs and executes the lighting pattern of the movie.

The art director is responsible for designing and creating the sets. He or she makes blueprints and sometimes models of the sets. Once the designs are approved, the art director oversees their construction.

The costume designers and their crew are responsible for designing and making the costumes. They may also purchase costumes for the production. In preparing their work, the designers must consider the work of the director of photography and the art director. The colors and patterns used on walls and in the lighting will affect the work of the costume designers. They can create a feeling of harmony by designing costumes that blend with the background. If the costumes clash with the sets, the audience can be subtly informed that the characters are out of place with their surroundings.

Through a series of meetings, the director and the heads of the various production departments discuss their understanding of the script and how to translate it into props, costumes, hairstyles, color, lighting, compositions, and camera movements. This close collaboration and exchange of ideas will lead to the planning of the film's design.

During the preproduction period, a crucial decision faces the producers, director, director of photography, and the art director. They must decide whether to film each scene on a *sound stage*—an artificial set constructed in a building—or on *location*—a real place that resembles the one depicted in the story. This decision affects both the look and the budget of the film. Most films combine both location and sound stage filming. The advantages and disadvantages of each technique are discussed under *Production.*

The director of photography, *right,* tries to create the best look for the movie. The director of photography supervises the camera crew and designs and executes the film's lighting.

Developing the shooting schedule is the job of the production manager. Knowing how the director wants the film to look gives the production manager a feeling for how long and how difficult the filming will be. A number of variables help determine how many days the crew will need to shoot the film. These variables include traveling to distant locations, construction of elaborate sets or lighting setups, and planning long and complex camera movements. By knowing how many days will be needed, the production manager can plan a schedule for shooting the motion picture.

Makeup artists apply cosmetics to help an actress's coloring look natural under the bright lights needed for filming.

© Gale M. Adler, Shooting Star

The costume designer creates the motion picture's costume designs, oversees their production, and makes sure they suit the actors and actresses.

To save time and money, the production manager plans a schedule in which most of the scenes will be shot out of the order in which they appear in the script. For example, if scenes one, five, and nine all take place in the same living room, it will save time and expense to shoot them all at once. This way, the crew only has to set up the lights once and the production manager only has to organize the materials needed on that set once. If the scenes were shot in the order in which they appear in the script, the crew would have to set up its equipment three separate times.

Preparing the final budget. With the shooting schedule prepared, the production manager can begin laying out the actual cost of the film. The manager must stay within the guidelines of the estimated budget and the amount of money raised from the investors. The manager can specify what equipment to use and how much it will cost, and can decide how much time will be needed to edit the film. A shorter time will be required if the director plans the film carefully in the preproduction stage. More time will be needed if the director *improvises* on the set. Improvising means that, as the film is being shot, the director works to discover the best way to play a dramatic moment or find the most appropriate camera position.

The production manager makes a final budget after reviewing the script for its costume, location, and acting needs, and after identifying the necessary equipment and size of the crew. The final budget includes *above the line* costs and *below the line* costs. The above the line costs are the salaries for key actors and actresses, the fees for the producers and director, and the purchase of the script and other creative fees. Below the line costs include crew salaries, equipment rentals, insurance costs, film and sound stock purchases, and rent for editing rooms. The producers and the director then review the budget and shooting schedule. They may request adjustments to figures they feel are unrealistic.

During the preproduction period, the producers and production manager refine the budget. They plan how the budget will be spent day by day until the film is completed and ready for distribution. The production manager and the assistant director work with the heads of the various departments so they can plan their work to meet the needs of the schedule and the budget.

Assembling the cast. As the budget and shooting schedule are being completed, the director works with the producers and casting director to complete the cast. The casting director's job is to screen the applicants. He or she sometimes considers hundreds of actors and actresses for each major role in a film. Through a series of auditions and interviews, the selection is narrowed down to a few candidates for each role. At an audition, a

© Gale M. Adler, Shooting Star

Preparing to shoot a scene, the various technicians set up their lights while another crew places the sound gear in position to record the action on audiotape. Adjustments in equipment placement may be made to film different versions of a single shot.

performer may be asked to read from the script or to act in a scene previously prepared. The director and producers select the final cast from the pool of performers identified by the casting director. Actors and actresses are chosen for their talent and their ability to blend with other performers to create a team performance. The actors and actresses are also selected for how appropriate they are for the role, based on their appearance, temperament, and the director's interpretation of the role.

Holding rehearsals. If time permits and the performers are available, rehearsals take place before shooting. During rehearsals, the director and the cast explore the characters and script together. They read through the script and discuss the story and the role each character plays in it. They then act out the scenes and rework them to fit their talents and interpretations. They may use improvisation to explore each character and the possible ways to play a scene.

Not all directors hold preproduction rehearsals. Some only discuss the story and characters with performers at this time. They prefer to wait until the actors and actresses are actually on the set to rehearse each scene. Performers with small parts usually meet the director for the first time the day their scene is shot.

© Shooting Star

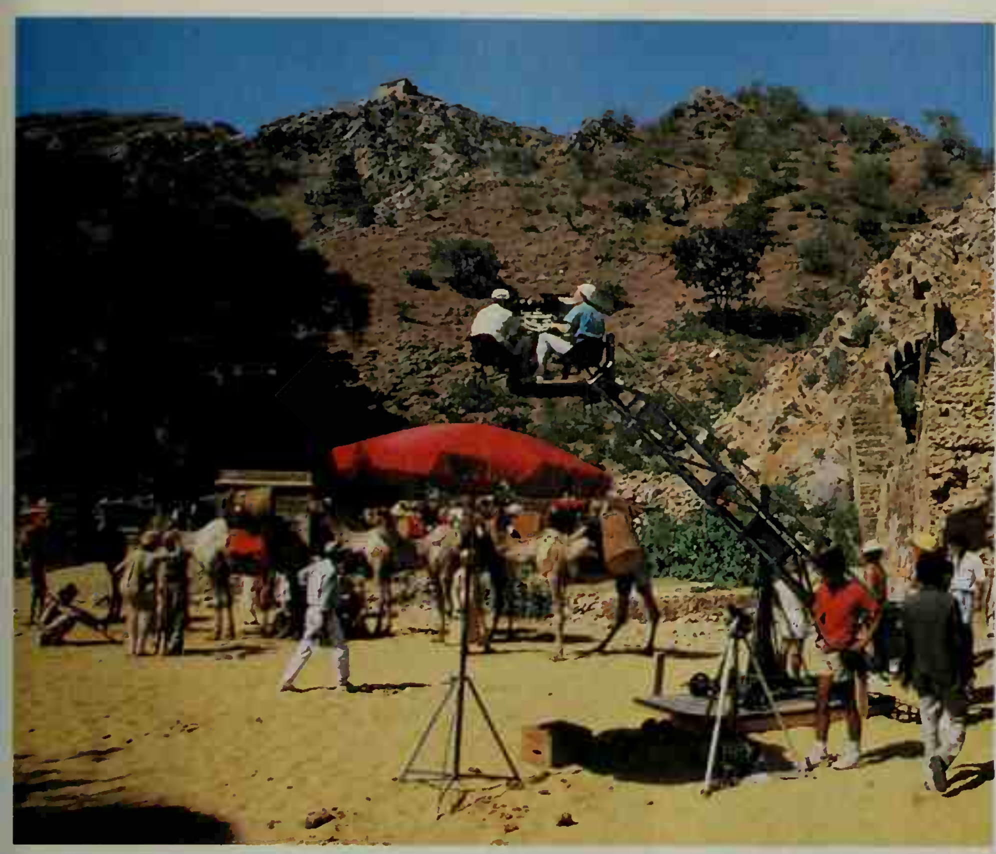
Building a set usually takes place on a sound stage. The art director is responsible for designing the sets. After the designs are approved, the art director oversees their actual construction.

Production

During the preproduction period, the filmmakers imagine the movie they want to make. They gather the people and materials needed to realize their idea. During the production period, the movie-as-imagined is brought to life and recorded on film and audiotape. The creative work of the preproduction period is continued and extended. However, instead of working with words or drawings or budgets on paper, the filmmakers work with actors and actresses and the materials of real life.

Filming on a sound stage. A sound stage is a hangarlike building in which sets can be built. Shooting on a sound stage enables the production team to design and build the sets to exact specifications. It allows them to place the camera exactly where they desire, and to create precise scale and details in their sets. Achieving the desired lighting is easier because each stage has a grid of pipes suspended from the ceiling. This grid allows the director of photography to hang each lighting unit with precision. The stage is enclosed, which eliminates noise and distractions from the outside world. Working on a stage saves time when setting up, and it eliminates moving the film's company from place to place because everything is shot right on the sets.

The disadvantage of filming on the sound stage is the extra cost. Constructing sets is much like building a house. A designer must make architectural plans of the set. Carpenters must build it and the set must be painted and furnished.



Filming on location. The advantage of shooting on a location is that the set already exists, for example, a skyscraper, a mountain, or a harbor. Additions can be made to the location to create the appropriate look. If, for instance, the scene needs a driveway but there is none at the site, a false driveway can be added.

The main disadvantage of shooting on location comes from the fact that locations were not designed for filmmaking. The filmmakers may not have the room to spread out their equipment and freely move the camera. They must bring in generators to supply enough electricity for their lights. The location is more difficult to protect from outside intrusions, such as pedestrians, noise from traffic and airplanes, and changes in light throughout the day. The cast and crew must be transported to the locations, which may be in distant parts of the world. The personnel must be fed and housed. However, the success of many films comes from the authentic look and feel of the location, which outweigh the disadvantages.

Some filmmakers shoot outdoor scenes on a *back lot,* an open air area on studio property. A back lot set is a re-creation of an exterior, such as a city street. Filming on a back lot saves time and money that would be consumed shooting on location. However, the results may be less authentic-looking than location shooting.

Preparing to shoot. The location or the set on the sound stage must be carefully prepared before the camera can interpret the action. The shooting day usually starts very early. Trucks begin arriving with lights, props, and camera and sound equipment at 6 or 7 a.m. The *set decorator* arranges the props. Hairdressers and makeup artists arrive just before the performers. The actors and actresses spend from one to several hours having their hair and makeup prepared for each day's shoot. The craft services crew puts out coffee and donuts for the crew as they set up. The director and assistants review the schedule for that day's work. The director of photography directs electricians called *gaffers* in setting up the lights.

The set must be lit brightly enough for an image to be made on film. Lighting a scene is one of the most time-consuming and important aspects of film production. Lighting creates a mood or a tone for each scene. The lighting director or director of photography uses contrast as a major tool. Contrast is the relative brightness of a character or object against surrounding shadows

Filming on location provides a movie with realistic settings that might be difficult, as well as more costly, to create at a studio. But on-location shooting also has disadvantages. For example, personnel and equipment must be transported to the location, which can present problems in isolated areas.

© Mikki Ansin, Gamma/Liaison

and darkened areas. A happier, more upbeat mood can be created by lowering the contrast and making the scene brighter. A scene filled with shadows and set off by a few small areas of bright light is usually more somber. In a mystery movie, a threatening tone can be developed in a darker scene emphasizing heavily contrasting light. An audience sits in expectation, waiting for something or someone to jump out of the shadows.

As the lighting is being adjusted, the performers and director come to the set. They review their work from the rehearsal period, focusing on their characters' actions and reactions in the upcoming scene. For unlike live theater, where the performer acts in a continuous time sequence, film requires a performer to work in fragments of scenes. Each shot in a film seldom covers more than a minute or two of the film's story, and, as explained earlier, the scenes themselves are shot out of order. Consequently, film performers must develop their characters without the help of continuity, and the actors and actresses must have a strong sense of the film's time sequence. Acting in fragments does have some advantages, however, over stage acting. In the movies, the performer can concentrate on the very short sequences of dialogue or movement that go into a given shot.

Shooting the movie. After the lighting preparation is completed, the director and performers go onto the set and rehearse in front of the camera operator and a technician called the *sound mixer.* The director works with actors and actresses to polish their performances. In addition, the camera operator checks to be sure that the photography will be satisfactory, and the sound mixer makes certain that a good clear audio recording can be made. Then the shot is recorded on film and on smaller audiotape. Usually, there are several *takes* (versions) of each shot. The director may call for a retake to improve upon a performance or to ask for a different interpretation of the scene. The performer may want to try a new approach, or the camera operator may want to improve the framing of the shot or the camera movement.

© Eva Sereny, Sygma

Lighting is responsible for much of a scene's dramatic effect. In this shot from a horror film, the shadowy background contrasts with the brightly lit faces to heighten the tension.

Much of the shot's impact depends on the choice of camera lens and position, and on the *blocking* of actors and actresses. A long lens known as a *telephoto lens* makes a scene look flat. A *wide-angle lens* deepens space. Camera position influences how an audience understands a scene. For example, if the director places a camera so that it looks at a character through a fence, the audience will probably feel that the character is closed in, almost imprisoned.

Blocking refers to how the performers move during a scene. If a character moves toward the camera and grows large in the frame, he or she will take attention away from the other performers in the frame. If characters walk away from the camera, the audience will feel that the figures are isolated or vulnerable or less important, depending upon the preceding action and scenes.

Filmmakers use a device called a *clapstick* to identify the takes, shots, and other information that they will need during the post-production stage. A clapstick consists of a slate attached to two hinged boards. The slate is marked with the number of each scene and take. The camera operator photographs the clapstick before each take, thus visually identifying the scene and take number. A member of the camera crew also says aloud the scene and take numbers, and then claps the two boards together to make a sharp sound. The spoken information and clapping noise are recorded on the sound track, creating an audio record just as the slate preserves a visual record of the filming.

After each take, the director consults with the performers, the director of photography, and the camera operator. They decide on any adjustments that could improve the shot. Traditionally, they had to rely on their instincts of how the take would look on the film. Since the 1970's, however, many directors have used a *video assist* to help judge the takes as they are shot. The video assist is a video recording system attached to the movie camera. It records an image on videotape while the camera is filming. The videotape can be examined immediately after shooting, an advantage over the camera film, which must first be processed in a laboratory. The video assist thus provides the filmmakers with a faster way to judge each shot, allowing them to determine what improvements they need to make in the next take.

© Dick Luria, FPG

A clapstick is a hinged board used to keep track of a movie's scenes, takes, and other important information during filming.

On a low-budget film, the filmmakers may do only three or four takes from each camera setup. On a big-budget film, as many as 50 takes might be made. After the director feels satisfied with a take, it is *printed*—that is, sent to the laboratory for processing. A copy called a *work print* is then made of satisfactory takes for the editing phase. To save money, unsatisfactory takes, called *NG* (no good) *takes*, remain as negatives.

After all the takes of a shot have been made, the crew, supervised by the director of photography, sets up the lights and camera angle for the next shot. The performers go to their dressing rooms, or to their trailers if they are on location, to wait for the crew to complete its work. Meanwhile, the director talks to the designers about the next day's set. The director may also meet with the producers and production manager to discuss the schedule, budget, or other production-related matters. At the end of the day, if the work is on location and completed, the crew packs and moves to the next location.

Post-production

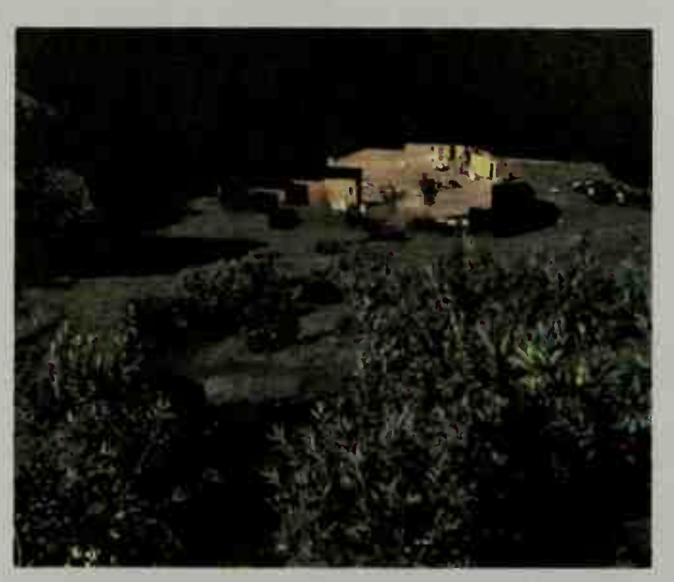
The production stage provides the raw materials from which the motion picture will be constructed. This raw material consists of fragments of film and audiotape. The fragments record the characters, places, and events that make up the film's story and interpretation. Post-production is the stage during which the raw material is edited into a motion picture. Editing refers to the total process of putting a movie together in a final form. In many ways, editing resembles the writing stage of filmmaking. But instead of constructing the story out of words, the editor and director select the best shots and dialogue. They use them to lay out the movie's structure and to determine its moment-to-moment shape.

Throughout the process, the editors pay close attention to the rhythm and tempo of the film. They carefully choose where each shot begins and how it flows into the next shot. Every aspect of the film is analyzed and evaluated during editing. If necessary, the movie can be reinterpreted at this stage to take advantage of its strengths and to diminish its weaknesses.

Preliminary steps. The editing process begins after a sequence of important steps to prepare the *camera original* and the sound track for editing. The camera original is the film exposed during the production stage. First, the camera original is processed as a negative, and selected takes are printed as positives from it to become the work print. Filmmakers use the work print during the editing to preserve the camera original from damage. The sound on the audiotape must be copied onto a tape the same width as the film. Matching the size of the film and tape allows the editor to put the sound track and picture on the same machine while editing.

Next, the sound must be brought into *synchronous* relationship with the picture. This means the sound must be placed so it exactly matches the action in the picture. For example, when an actor speaks on the film, the audience should hear his voice at the same time. On the film, an assistant editor marks the clapstick frame where the boards close. The assistant then marks the corresponding clapstick sound on the sound track. Lining up this sound and the appropriate picture frame assures the synchronous relationship. The assistant editor has to find and establish this synchronous relationship for

The editor examines the film on the screens of a device called a *flatbed editing machine.* The editor selects the desired shots and then arranges them into an order that will tell the film's story.



every shot in the film. After the film and sound have been "synced up," the assistant editor makes a detailed written record of each shot. This log enables the editors to keep track of the thousands of feet of exposed film.

If the film editors will use a computer editing system, they run the work print through a *telecine* (pronounced *TEHL uh SIHN ee)* machine, a device that converts film images to TV signals. Both the pictures and the sound are then *digitized*—that is, turned into numeric form—and stored in a computer.

The rushes. Next, the director and editor screen this raw, unedited footage, called *rushes* or *dailies.* They discuss which shots to use and sketch out how the shots should be arranged. These screenings usually take place at the end of each day's shooting during production—an example of how the different stages of making a movie overlap. The editor, director, producers, and other crew members see the footage from scenes filmed the previous day. In this way, they can check on the quality of their work. If necessary, they can adjust their approach. They can reshoot a single shot or an entire scene before leaving a location. They can also create new scenes to fill in gaps in the story they did not realize existed. Most important, they can begin the actual editing process.

The rough and fine cuts. Based on the discussions with the director and producers, the editor begins to assemble the selected footage and put it in order. This preliminary version of the film is called the *rough cut.* It follows the order of the screenplay, using the shots selected by the director.

Special effects create illusions. The top picture shows a painting on glass called a *matte* painting. The black area blocks out light. The middle picture shows a shot from a real set, also with a black area. At the bottom, the matte painting and the shot of the set—this time photographed with live actors—have been combined to create the finished scene.

After the editor completes the rough cut, he or she screens it with the director. Based on the director's response, the editor may use different takes of shots, and may change the order of scenes. Scenes that fail to add to the storytelling might be dropped. The editor makes these adjustments, which clarify, strengthen, and refine the story. This version is called the *fine cut.*

The director then screens and analyzes the fine cut with the producers. To get a fresh opinion, the filmmakers may invite friends and fellow filmmakers not involved with the production. They make additional adjustments to improve the story and the filmmaking. The director continues to supervise cuts until he or she is satisfied, given the limitations of the budget and the post-production schedule. In many cases, the studio or the producers then take over and polish, revise, or completely restructure the film as they see fit. But some directors have the authority to determine the *final cut* (finished version) of their films.

Adding music and sound effects. During the editing, the composer and sound editor join the other filmmakers. Some composers want to be involved from the initial planning of the film to absorb its mood and to understand its development. Most, however, come in during or after the rough cut has been completed.

The composer and sound editor will screen the motion picture with the director, identifying appropriate moments for sound effects and music. They discuss the kind of music the film calls for and the instruments that will be used in recording the music. Sometimes, the discussions result in a scene being reedited. The director may decide that some dialogue can be effectively replaced by music.

As the composer prepares and records the music, the sound editor adds sound effects, background noises, and additional dialogue. These sounds contribute to the character and impact of the film and strengthen the desired illusion.

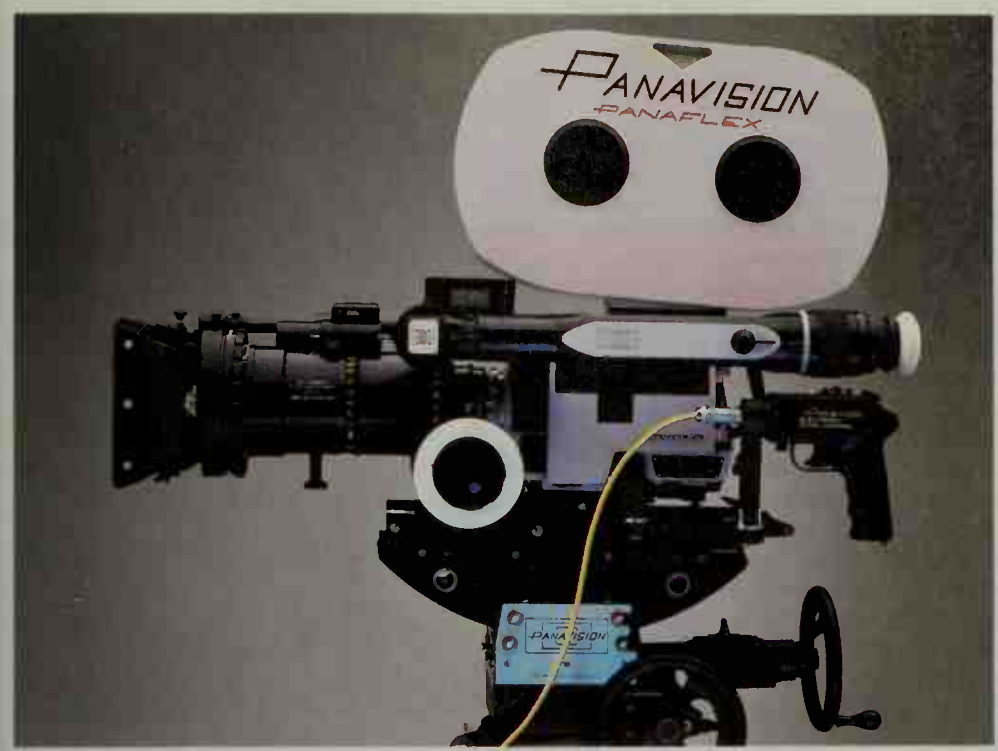
Mixing the sound. The various sounds and music are blended together onto one track during a *mixing session* in a mix studio. Several technicians—usually a dialogue mixer, a sound effects mixer, and a music mixer—sit behind a large console with many volume and sound effects controls. In front of them is a screen on which the film is projected. The director watches the film with them as the mixers follow carefully prepared charts known as *cue sheets.* These sheets indicate when each sound occurs in the film's sound tracks. The mixers work together under the leadership of the dialogue mixer. They adjust the relative volume and sound quality of each sound to emphasize the most important sounds.

WORLD BOOK photo by John Hamilton, Globe Photos

In a mixing session, technicians called *sound mixers* blend the individual sound tracks for the dialogue, music, and sound effects onto a master tape. The mixers watch the screen action as they operate controls on their *sound console* to switch the sound tracks on and off, and to balance the various sounds.

Computer editing. Today, most film editing uses specially adapted computer systems known as *nonlinear editing systems.* These computer systems store both sound and pictures in *digital* (numeric) form. The editing systems are called *nonlinear* because film editors can quickly call up images or bits of sound from the computer's digital files in any order instead of scrolling through a length of tape in linear fashion looking for what they want.

Nonlinear systems enable editors to accomplish complex changes in minutes or even seconds. At any time during the process, an editor can instantly replay any shot or series of shots on a television monitor with any choice of sound accompaniment. Editors no longer have to physically splice lengths of film together and store them in massive filing systems. When the editor is satisfied with the final edited version, the motion picture is said to be *locked.* The editing system then produces an *edit decision list* (EDL), a computer file that records all the images and sounds to be used in the film.



Although both picture and sound editing are now largely done using computers, the procedure remains much like traditional processes. The difference is the computer's ability to simultaneously replay multiple segments of picture and sound, and to reproduce the results as a finished movie on a TV monitor.

The new computer technology greatly reduces the cost of filmmaking. It also allows the creation of special effects that in the past would have been too costly or even impossible to create.

The answer print. After the picture has been locked and the sound editing completed, the filmmakers take the *final* or *frozen cut* to its last production phases. The camera original is edited, shot for shot, to exactly match the final cut of the work print. If the filmmakers used nonlinear editing technology, the system uses the edit decision list (EDL) to create the finished film from the camera original.

Next, the laboratories print a new copy on a single, continuous piece of film. They then copy the mixed sound track along the edge of this new print, creating an *answer print.* This version includes the motion picture's titles and credits, as well as optical effects that were decided upon during the editing. The filmmakers can make small adjustments at this point. By reprinting, they can make individual shots darker or lighter, or adjust their color.

When the filmmakers believe their work is complete, they preview the picture for an outside audience. Based on the audience's response, whole scenes may be reedited and reprinted. After the filmmakers are satisfied with the film's appearance, the post-production stage is complete. The product is now ready for distribution.

A 35-millimeter motion picture camera is a complex piece of equipment. The film is housed in a lightproof, soundproof *magazine* that is mounted atop the camera. Unexposed film unwinds from a reel in the magazine's *supply chamber.* As the film moves through the camera, it is exposed by light entering through the lens and winds onto a reel in the *take-up chamber.* Knobs on the side of the camera focus the lens and wheels at the base of the camera adjust its position.

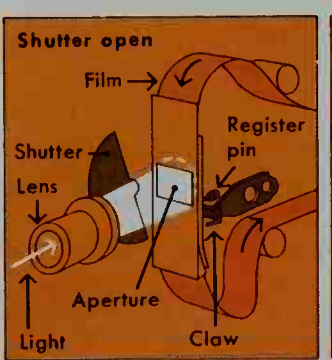
Panavision

As we watch a motion picture, we are actually watching many thousands of individual still pictures called *frames.* Each new frame shows an image slightly different from the image in the preceding frame. When a single image is flashed upon a screen, the human eye continues to see it for one-tenth of a second after the screen has gone black. Because of this phenomenon, called *persistence of vision,* we see a continuous flow of action when viewing a series of images flashed in rapid succession.

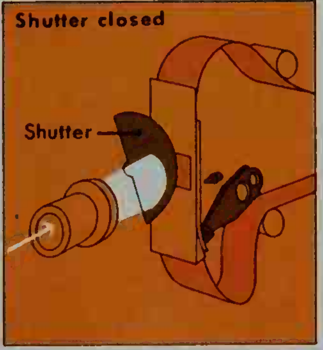
The camera. In principle, a movie camera is like a still camera except that it takes many pictures each second. In addition, the camera mechanism is precision-engineered to run almost noiselessly to avoid interfering with sound recording.

The camera lens focuses an image, consisting of light rays, upon a single frame of unexposed film. The image boundaries are precisely defined by a rectangular opening called the *aperture.* After the frame has been exposed, a revolving shutter closes, temporarily shielding the aperture from further light. A metal tooth called a *claw* automatically engages the *sprocket holes* on the side of the film. The claw quickly moves the exposed frame down, pulling a fresh frame into position. While a *register pin* holds the unexposed frame in exact position, the shutter revolves and a burst of light exposes the new frame.

The film's stop-start movement is called *intermittent motion.* This cycle takes place 24 times a second for sound film. For slow-motion filming, the camera mechanism is run faster. For faster motion, the mechanism is run slower than 24 frames a second. The images are then projected at the normal 24 frames a second.



Unexposed film is loaded into the *supply chamber* of a lightproof *magazine,* which can be rapidly mounted and removed from the camera body. After the film has been exposed, it passes into the magazine's *take-up chamber.* It is then unloaded in the dark and sent to a film laboratory for processing.

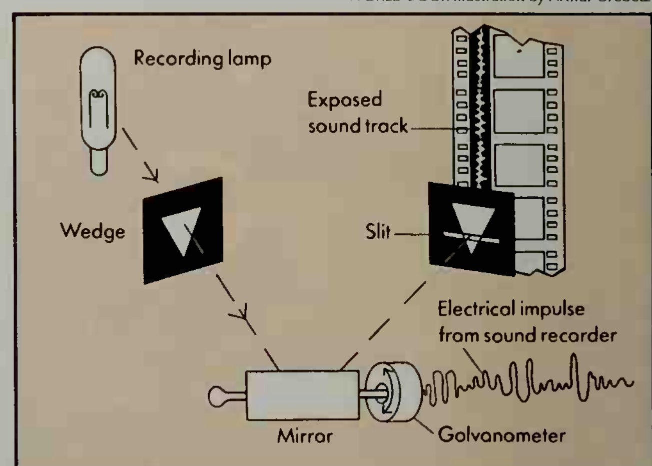


The film is made of light-sensitive chemicals called *emulsion* coated on a flexible plastic strip called a *base.* Any camera can use either black-and-white or color film. Film length is expressed in feet, but the standard widths are given in millimeters.

The oldest film in current use is 35 millimeters (about $1\frac{3}{8}$ inches) wide. This size was originally introduced in the United States in 1899 and soon became the standard width for making motion pictures. Almost all film shot for theater exhibition is 35 millimeters wide. Film shot for television and for classroom use is 16 millimeters (about $\frac{5}{8}$ of an inch) wide. Home movie film is 8 millimeters (about $\frac{1}{4}$ inch) wide. The wider the film, the larger the area of the frame and the greater the image's *res-*

The shutter controls the length of time that light strikes the film. When the shutter is open, light travels through the lens and an opening called the *aperture* onto the unexposed film. The register pin holds the film motionless until one frame has been exposed. The shutter closes, and the pin then withdraws. A claw is next inserted into the sprocket holes. It pulls the film to the next frame. This cycle is repeated 24 times a second.

WORLD BOOK diagrams by Mas Nakagawa



olution (detail). Movies projected in theaters show the largest image and thus use the largest film size. Occasionally, a filmmaker will shoot a movie using 70-millimeter ($2\frac{3}{4}$ -inch) film, which is costly but produces exceptionally sharp images on the screen. The giant screen *IMAX* movies use 70-millimeter film.

The sound track is a narrow band recorded on the side of the film image. For information on how the sound is mixed and recorded, see the section *How motion pictures are made.* The sound track appears on the film as a photographic recording that can be optically played back through a projector.

The sound is transferred from the magnetic tape to the photographic film by means of a *galvanometer,* an instrument that reacts to varying electric currents. At the heart of the galvanometer is a coil of wire that turns when an electric current passes through it. The direction and distance that the coil turns varies according to the direction and strength of the electric current. In this case, the current is produced by the magnetic sound recording. A wedge-shaped beam of light is projected onto a mirror attached to the coil on the galvanometer. As the coil quivers in response to the sound recording, the mirror vibrates accordingly, which in turn makes the reflection of the wedge-shaped beam tremble. This

The sound track is photographed on film by a beam of light, shown by the dashed line. The beam shines from a recording lamp through a lens that shapes it into a wedge and focuses it on a mirror. This mirror vibrates in response to the electrical impulses made by the magnetic tape recording of the sound track. The vibrating mirror reflects the wedge-shaped beam up and down across a slit in another lens. This exposes a pattern of light on the film. The pattern is converted back into sound when the film is run through a projector.

WORLD BOOK illustration by Arthur Grebetz

The projector mechanism projects the film image on a screen and also reproduces the sound. The projector has sprockets that pull the film through its mechanism. A rotating shutter prevents light from reaching the film until each frame is stationary. To reproduce the sound, an exciter lamp sends a narrow beam of light through the photographic sound track. The variations of light emerging on the other side shine into a photoelectric cell and are converted into electrical impulses. The tiny impulses are then greatly amplified and fed into the theater loudspeaker system.

Film for home movies is 8 millimeters wide. TV and classroom movies are shot on 16-millimeter film. Most theater movies use 35-millimeter film. Two white bands of sound track run down the left side of the 16- and 35-millimeter films.

trembling beam is reflected through a slit-shaped aperture and onto the film. This action produces a continuously changing area of exposed film called a *variable-area sound recording.*

The projector reproduces the film sound track and throws the visual images onto a screen. Like a camera, the projector has sprockets that pull the film through its mechanism. It also uses the intermittent-motion principle to hold each frame stationary during the projection. Some of the earliest cameras could even be adapted to serve as projectors.

In the modern projector, a rotating shutter prevents light from reaching the film until each frame is stationary. Then the shutter allows the bright light source to shine through the film and project the image through the focusing lens onto the screen. To minimize a flickering image, the shutter produces two short flashes of light for each projected frame instead of one long one. In a single second of film projected at 24 frames a second, there are 48 flashed images. Some projectors use a pulsing light source, which eliminates the need for a shutter.

The projector mechanism must allow for different principles of sound and film reproduction. At the point where the image is projected onto the screen, the film is moving in the intermittent, start-and-stop fashion just described. However, sound can only be *read* (reproduced) from film while running in continuous motion. To resolve this problem, the *sound head*—the device that reads the sound track—scans the film after it is past the lens and is again moving in a continuous motion. To permit the image and its matching sound to be reproduced at the same time, the sound must be recorded ahead of its corresponding image on the film. In 35-millimeter film, for example, the sound track is advanced 21 frames ahead of its corresponding image.

To reproduce the sound, an *exciter lamp* sends a narrow beam of light through the photographic sound track. The variations of light emerging on the other side shine into a photoelectric cell, where light is converted into electrical impulses. These tiny electrical impulses are then greatly amplified and fed into the theater loudspeaker system. If a motion picture has a stereo or quadraphonic sound track, multiple sound tracks are recorded on magnetic strips coated on the release print. The strips are read by a projector equipped with magnetic replay heads.

The screen. A typical theater screen is made of white plastic stretched on a metal or wooden frame. The screen is coated with millions of tiny glass beads. The beads make a highly reflective surface that looks equally bright no matter where the viewer sits in the theater. Screens vary in size, depending upon the size of the theater in which they are used. Since the late 1960's, smaller screens have become more common as many theaters have become multiplexes consisting of several smaller theaters, each showing a different motion picture.

The sound system's loudspeakers are placed behind the screen, which has thousands of small holes that allow the sound to pass through. There are 20 to 30 holes per square inch (3 to 6 per square centimeter). The holes are too tiny to be seen by the audience, so the sound seems to come from the picture itself.

Strong International

A 35-millimeter projector is used to show motion pictures in theaters. A modern projector is fully automated and may have a capacity of more than four hours of continuous programming.

The motion-picture industry

Movies are a billion-dollar industry. There are hundreds of thousands of screens throughout the world showing movies. Millions of people each week buy tickets to see a movie.

The motion-picture industry is divided into three branches—production, distribution, and exhibition. From about 1915 to the late 1940's, large movie studios in the United States dominated all three branches of the industry worldwide. The studios not only made the films, they distributed them to the theaters, the biggest and most important of which they owned.

In 1948, the Supreme Court of the United States ruled that studio control over production, distribution, and exhibition was an illegal monopoly. The court ordered the motion-picture studios to give up their role as exhibitors. By 1953, most of the Hollywood studios had sold their movie theaters.

Also during the late 1940's, the studios began to curtail their role in the production of movies, partly because of economic competition from television. The studios discovered that, in most cases, they could earn more money by financing and distributing movies made by independent producers.

Since the 1940's, film production in other countries has greatly increased. India's motion-picture industry, for example, produces hundreds of films yearly. France ranks as the leading film-producing country in Europe.

This section deals with the distribution and exhibition of movies in the United States. For information about production, see the section *How motion pictures are made.* This section also describes attempts by government and private organizations to censor movies and the industry's attempts at self-regulation. The section ends with a discussion of film festivals and awards.

Distribution. Distributors are responsible for advertising the film and delivering it to its audience in theaters and in homes through television, videocassette, or DVD. Major studios serve as the distributor for most American films. Independent distribution companies handle the remainder.

Some producers secure distribution before the film is even made. At this early stage, distributors might be interested in the movie because of its star or because the film will be a sequel to a popular film. If the producers have not obtained distribution before filming, they usually wait until the final print of the film is made before presenting it to distributors.

The distributor charges the film's producer a fee of 30 to 50 percent of all the money the film takes in. A new producer may have to pay a larger fee to attract a distributor than does an established producer with a record of profitable films. Distributors also charge for making the copies of the film sent to the theaters and for advertising and publicizing the film. The costs of copying, advertising, and publicity come out of the first money the film earns. The producer gets money only after these costs and the distribution fees have been deducted. The distributor can thus make a profit on a picture, while the film's producer may earn nothing.

After the producers and distributor arrange a distribution deal, the distributor carefully identifies the film's audience. The distributor generally arranges for *sneak previews* to judge the film's effectiveness and to identify its main audience. At a sneak preview, the distributor assembles an audience that may be chosen for such characteristics as age, income level, or occupation. During the screening, the distributor's staff usually watches the audience, observing their reactions and level of enjoyment. Afterward, the audience may be asked to fill out information cards on their reaction to the film. They may also meet with the distributor's staff to discuss their reactions. After reviewing the preview responses, the distributor designs the advertising campaign and decides how to release the film most effectively. Sometimes, the audience responses prompt the distributor to ask the producer to reedit or reshoot parts of the film.

Films with a broad appeal will receive widespread distribution, perhaps opening in thousands of theaters on the same day. Films with more specialized audience appeal generally open in a few carefully selected theaters. Widespread distribution is intended to quickly reach the broadest possible audience. The narrower or *platform* approach tries to build and sustain interest in the film over time with good critical reviews and favorable word-of-mouth from pleased viewers.

Most advertising campaigns are designed to make their heaviest impact for the first two or three weeks of a film's release. If the campaign attracts the right audience and these viewers enjoy the film, they will tell their friends and thus sell the movie to a new audience.

Advertisers sometimes design a second campaign to appeal to a different portion of the public. For example, the film may be an action movie with a star not usually associated with action films. The first campaign might reach out to that part of the public interested in action movies. The second campaign would be designed to attract that part of the public interested in seeing the star. The advertising campaign and the film's theatrical release also prepare the way for the film's release on videocassette and DVD, which have become major markets for distributors. Some films are released directly on videocassette, bypassing theatrical release entirely.

If the film can earn three times its budget in ticket sales during its first year of domestic release, the producers and their investors will begin to make a profit. The film will then be considered a commercial success. Other sources of revenue include foreign distribution, sales to TV, and videocassette rentals and sales.

Exhibition. Financial arrangements for exhibiting a movie can be complicated and may vary from film to film. In the simplest arrangement, the distributor charges an exhibitor a flat fee. More commonly, the exhibitor pays the distributor a percentage of the weekly box-office profits (box-office receipts minus theater operating expenses), often with a minimum payment guaranteed. For example, a distributor may require 90 cents of every dollar of profit from an exhibitor during the first week if the film is expected to be a hit. The percentage would then decline in succeeding weeks of the film's run at the theater. Typically, however, the exhibitor keeps about 50 cents of every dollar collected from ticket sales. The other 50 cents goes for costs of distribution and production. The flat fee or percentage the exhibitor pays the distributor is called the film's *rental.*

Theater owners place bids with distributors for the films that they want to exhibit. The limited number of films produced has forced exhibitors to bid higher and higher against one another for the right to rent espe-

cially desirable films. Exhibitors, in turn, have raised ticket prices.

Censorship and self-regulation. During the first half of the 1900's, several state and local governments had censorship boards that reviewed all movies before they could be shown in their areas. Some civic and religious groups also had boards that advised members whether they believed a movie to be offensive.

Censorship remained a major factor in the American movie industry until the 1950's. Beginning in 1952, the Supreme Court of the United States made a series of decisions that undercut the legality of the local and state boards. In 1965, the last strong state censorship board—that of New York state—went out of existence.

The motion-picture industry's efforts to regulate itself date back to 1922, when the movie studios established the Motion Picture Producers and Distributors of America. This organization reviewed movie scripts before filming began, to delete material that the organization felt might be considered offensive.

In 1945, the organization became the Motion Picture Association of America. In 1968, the association adopted a classification system. Instead of reviewing scripts before production, the association rates the completed film as to its suitability for various ages. The association classifies films into five categories: *G*—general, all ages admitted; *PG*—all ages admitted, but parental guidance suggested; *PG-13*—all ages admitted, but parents are strongly cautioned to give special guidance for attendance by children under 13; *R*—restricted, persons under 17 must be accompanied by a parent or guardian; *NC-17*—persons under 17 not admitted.

Festivals and awards. The first major film festival was held in Venice, Italy, in 1932. Today, hundreds of festivals are held annually. The largest and probably best-known festival is held in Cannes, France. Other important festivals take place in Venice, Italy; Berlin, Germany; London; Moscow; New York City; Park City, Utah; and San Sebastián, Spain.

The best-known movie awards are made each year by the Academy of Motion Picture Arts and Sciences. These awards, called the Academy Awards or Oscars, are presented for outstanding achievements in filmmaking during the preceding year.

The Oscar is a gold-plated bronze statue presented to winners of the Academy Awards. The statue received its name in 1931, when an Academy librarian said it resembled her Uncle Oscar.

A number of organizations of critics issue annual film awards, including the National Society of Film Critics and the New York Film Critics Circle. The Hollywood Foreign Press Association gives the annual Golden Globe Awards. The best-known awards given annually in other nations come from the British Academy of Film and Television Arts. Its awards resemble the Oscars.

George Eastman House

The first successful photographs of motion were pictures of a horse. Eadweard Muybridge, a British photographer in the United States, took them in the 1870's using a row of still cameras.

Since earliest times, people have been interested in portraying things in motion. During the late 1800's, developments in science helped stimulate a series of inventions that led to projected motion pictures on celluloid film. These inventions laid the foundation for a new industry and a new art form.

The first successful photographs of motion were made in 1877 and 1878 by Eadweard Muybridge, a British photographer working in California. Muybridge took a series of photographs of a running horse. For his project, Muybridge set up a row of cameras (first 12, then 24) with strings attached to their shutters. When the horse ran by, it broke each string in succession, tripping the shutters.

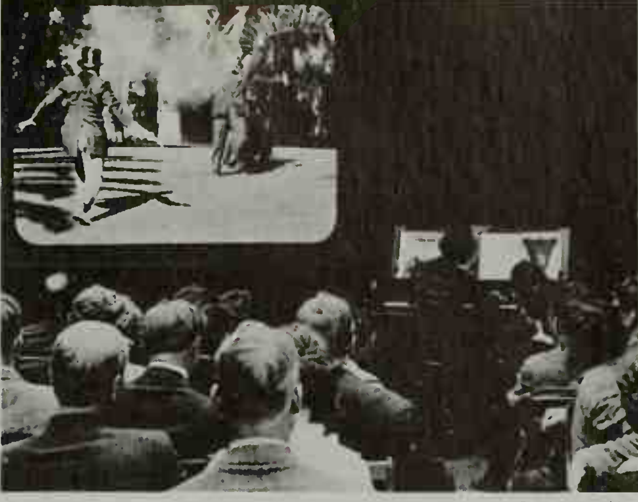
The invention of motion pictures. Muybridge's feat influenced inventors in several countries to work toward developing devices to record and re-present movie images. These inventors included Thomas Armat, Thomas Alva Edison, C. Francis Jenkins, and Woodville Latham in the United States; William Friese-Greene and Robert W. Paul in Great Britain; and the brothers Louis Jean and Auguste Lumière and Etienne-Jules Marey in France. Through their efforts, several different types of motion-picture cameras and projectors appeared in the mid-1890's.

Edison's company displayed the first commercial motion-picture machine at the World's Columbian Exposition in 1893. Edison called his machine the *kinetoscope.* It was a cabinet showing unenlarged 35-millimeter black-and-white films running about 90 seconds. An individual watched through a peephole as the film moved on spools. Kinetoscope parlors opened in a number of cities. However, they were soon replaced by projection machines that threw greatly enlarged pictures on a screen. These new machines allowed many people to view a single film at the same time.

The Lumière brothers held a public screening of projected motion pictures on Dec. 28, 1895, in a Paris cafe. Edison, adapting a projector developed by Armat, presented the first public exhibition of projected motion pictures in the United States on April 23, 1896, in a New York City music hall.

Early motion pictures. Film screenings soon became a popular entertainment. In large cities, motion pictures played on vaudeville programs, in music halls, and in amusement arcades. Traveling projectionists brought the films to smaller cities and country towns. The most popular subjects included re-creations of current news events, such as battles in the Spanish-American War of 1898, and dramatized folk tales.

Films were made without recorded synchronized sound. However, exhibitors sometimes accompanied the images with music or lectures, or even used offscreen live actors to provide dialogue. Later, printed *titles* were inserted within the films. The titles gave dialogue, descriptions of action, or commentary. Titles permitted the international circulation of films, because translated titles could easily replace the originals.



Edison's company dominated the early years of American moviemaking through its control of patents on filmmaking equipment. Edwin S. Porter, who worked for Edison as a director and cameraman, became a leader in shifting film production from current events toward storytelling. Porter's 1903 film, *The Great Train Robbery,* portrayed a train robbery and the pursuit and capture of the robbers. The 11-minute Western became a sensational hit.

The nickelodeon. Porter's film and the storytelling movies that followed opened the way for a major breakthrough in motion-picture exhibition—the *nickelodeon* theater. Beginning about 1905, thousands of these theaters opened in American cities, mostly in commercial

The first important movie was *The Great Train Robbery, above,* directed by Edwin S. Porter in 1903. It described a train robbery and the pursuit and capture of the bandits. Porter was the first director to use modern film techniques to tell a story.

Bettmann Archive

The first movie theaters were called *nickelodeons.* Most nickelodeons were stores converted into theaters by adding chairs. They charged 5 cents. They showed silent movies, while a pianist played music that suited the action on the screen.

areas or in immigrant neighborhoods. Many small stores were converted to nickelodeons by adding a screen and folding chairs. Admission was only 5 cents, much less than competing entertainment. Nickelodeons attracted a large new audience for movies, and laid the foundation for the growing profitability and expansion of the movie industry.

The birth of Hollywood. In the early years of American filmmaking, most movies were produced in New York City and New Jersey, though some were made in Chicago, Florida, and elsewhere. As the industry developed, filmmakers began working more and more in southern California. They were drawn by a climate suitable for year-round outdoor shooting and by the availability of varied scenery.

By the time World War I broke out in Europe in 1914, a number of companies had established studios in and around the Hollywood district of Los Angeles. After the war ended in 1918, American movies became dominant worldwide and the name "Hollywood" came to stand for the values and style of American movies.

D. W. Griffith was the most influential film director during the early years of Hollywood. Griffith pioneered many of the stylistic features and filmmaking techniques that became established as the Hollywood standard. His work brought wider appreciation to the movies as art and helped films attract a more educated and wealthier audience.

Griffith directed hundreds of short films between 1908 and 1913, and a number of feature-length films in later years. Throughout his career, which ended about 1930, he advanced a variety of stylistic improvements. Many filmmakers before and after Griffith regarded movies as filmed theater. They placed the camera a set distance from the performers, photographing the scene from a single viewpoint as a spectator would see it in the theater. Griffith liberated camera movement. He continually shifted the camera to different distances from the action. He established the close-up shot of a face, a part of a body, or an object as a basic part of film style. Using the close-up, Griffith also led his players toward an acting style of greater realism and psychological

Culver

The Birth of a Nation, directed by D. W. Griffith in 1915, was the first American motion-picture epic. The film dealt with the American Civil War and the period that followed. The movie featured spectacular battle scenes.

depth than was common at that time.

Griffith also revolutionized film editing. Instead of filming an entire scene in one shot, or a few shots, he broke up scenes into many shots, filming from different angles and distances. He extended this idea of film editing to include action at different locations so that the story moved swiftly from place to place in a style called *cross-cutting.* Griffith emphasized a quicker tempo of shots, of movement from place to place, and movement within a scene. As a result, his films established a breadth, freedom, and swift pace that characterized the treatment of time and space in later American motion pictures.

Griffith's most famous, and controversial, work was the epic *The Birth of a Nation* (1915). The film portrayed the American Civil War (1861-1865) and the following Reconstruction period through the eyes of two families, one Northern and one Southern. The film was praised as the first great American work of cinema art, but also criticized as racist for its portrayal of blacks and its sympathetic treatment of the Ku Klux Klan.

Movies become big business. About the time *The Birth of a Nation* was released, movie companies were developing a "star system" similar to those of other performing arts, such as theater and opera. Publicizing performers became the most effective means of promoting movies and attracting large audiences. The first highly paid and most popular motion-picture stars included dramatic performers Douglas Fairbanks, Sr., and Mary Pickford, cowboy actor William S. Hart, and comedian Charlie Chaplin.

Before World War I, foreign-made films were strong competition for American movies in the United States, especially mystery serials from France and historical epics from Italy. But during the war, European governments diverted raw material from their film industries for military needs. American movie companies seized the opportunity to become the world's strongest film industry. Their successes enabled producers to spend money on lavish costumes and expensive sets. The studios created a sense of glamour around American motion-picture stars that appealed to audiences throughout the world.

Within the United States, competition among movie companies led the most powerful studios toward *vertical integration.* This term describes the system in which a studio owned production facilities, distribution channels, and movie theaters. Vertical integration gave the studios control of all three major elements of filmmaking: production, distribution, and exhibition.

A few movie companies came to dominate the industry—Columbia, Fox, Metro-Goldwyn-Mayer, Paramount, RKO, United Artists, Universal, and Warner Brothers. They adopted a system in which producers supervised a movie's development from script to postproduction. Producers, who were usually businessmen rather than film artists, kept a close watch on budgets and schedules. As far as possible, all the people working on the film—the director, writers, designers, crew, and cast—were drawn from the studio payroll.

Vertical integration enabled the companies to use their studio stages efficiently and maintain a high volume of production. But the system placed an even greater emphasis on movie stars and familiar, repeatable *genre* movies. A genre film is a specific type, such as a Western or a crime melodrama.

Filmmaking in Europe. While American movies remained popular and profitable, more demanding viewers in the 1920's began to look to Europe for new developments in film art. Moviemakers in European countries often competed against American domination of their own theaters by developing distinctive film styles. This goal was perhaps achieved most successfully in Germany. There, many film directors, writers, and designers were also active in other arts, including painting and live theater.

In subject matter, German filmmakers stressed fantasy and legend, and also an intense psychological realism not often attempted in American films. The Germans often treated themes in a style drawn from a movement in the arts called *expressionism* (see **Expressionism**). Expressionist films used nonrealistic sets and unusual camera angles to represent a character's inner feelings. The best-known and most influential expressionist film was *The Cabinet of Dr. Caligari* (1919), directed by Robert Wiene.

One artistic approach in German cinema stressed lighting and camera movement. German filmmakers created a threatening visual mood to accompany their tales of the supernatural by making scenes darker than normal and by emphasizing contrasting light and shadow. A famous example is the horror movie *Nosferatu* (1922), directed by Friedrich Murnau. The same director also made *The Last Laugh* (1924), which told its story entirely through the visual images of the camera, eliminating descriptive and dialogue titles.

Filmmaking made advances in Russia, too, particularly after the Bolshevik (Communist) revolution of 1917. In 1922, the Soviet Union was formed under Russia's leadership, and it existed until 1991. In the Soviet Union, movies gained attention as an important medium for education and propaganda. Soviet filmmakers emphasized

The Cabinet of Dr. Caligari (1919) was a famous silent German horror film. The distorted sets reflect the twisted mind of the madman who narrates the story.

film editing, refining the *montage*. Montage is a technique in which many separate shots are used to create a single point.

Soviet director Sergei Eisenstein developed theories of how the arrangement of shots could create associations in the mind of the audience and stimulate emotions and ideas (see **Eisenstein, Sergei Mikhailovich**). Eisenstein put his ideas into practice in such important films as *The Battleship Potemkin* (1925), which raised the Soviet silent cinema to equality with German films in artistic prestige and influence.

The silent film classics from Germany and the Soviet Union, as well as France, Scandinavia, and elsewhere, were not experienced as silent by audiences. In most large theaters, the films were accompanied by music, often prepared specifically for the film and played by a large orchestra.

American film companies showed their respect for European artistic advances by inviting many foreign filmmakers from Germany, Sweden, Great Britain, and elsewhere to work in Hollywood. Friedrich Murnau moved to Hollywood about 1926. Even more widely known were performers like Sweden's Greta Garbo, who became one of the greatest stars of American motion pictures.

The movies talk. During the 1920's, engineers in the United States and Germany were working to develop a technology that could add synchronous recorded sound to movies. By the mid-1920's, a few systems were ready for demonstration.

The first sound film to create a sensation was *The Jazz Singer* (1927). Although silent for much of its length, in a few scenes the popular American entertainer Al Jolson sang and spoke in synchronous sound. The film used a system in which the sound from a mechanically recorded disc was mechanically synchronized with the film strip. This system was soon replaced by one that used electronic signals to record the sound directly on the film strip. The sound-on-film system was widely used by 1929.

The coming of sound marked a turning point in motion-picture history. Some historians claim sound was actually a setback for the artistic development of movies. The emphasis on sound, and the expense of developing it, limited other technological advances that filmmakers had been experimenting with in the 1920's. For instance, a wide-screen process demonstrated by French director Abel Gance in *Napoléon* (1927) was not generally introduced until the 1950's. What was affected the most, perhaps, was a kind of poetic cinema represented by such silent films as *The Passion of Joan of Arc* (1928), directed by Carl Dreyer of Denmark. Such films survived more as an experimental art form than as part of mainstream commercial motion pictures.

With the introduction of sound, motion pictures went through an awkward period of adjustment. Cameras had to be enclosed in soundproof boxes because the microphones picked up motor noise. More importantly, directors had to learn how best to take advantage of sound. But this adjustment period was brief. By 1931, one of Germany's major silent film directors, Fritz Lang, had made *M,* a sound film that remains a masterpiece of cinema. In 1928, Walt Disney issued *Steamboat Willie,* the first animated short film to use synchronized sound. For more information about animation in motion pictures, see **Animation; Disney, Walt.**

In Hollywood, sound introduced greater changes in personnel than in film style. Sound brought with it a flood of directors, dialogue writers, and, especially, performers from the Broadway theater. A number of silent

Hollywood musicals of the 1930's became noted for their elaborate staging. Dance director Busby Berkeley staged this spectacular World War I musical number in *Gold Diggers of 1933.*

Scene from *Gold Diggers of 1933* (1933), directed by Mervyn Le Roy; the John Springer Collection, Bettmann Archive

screen stars, notably Greta Garbo and the comedy team of Stan Laurel and Oliver Hardy, successfully made the transition to sound. However, others did not, either because of unsuitable voices or problems with what the studios considered excessive salaries.

Movies in the 1930's. Two important new genres in American movies came from Broadway in the 1930's, the musical and the gangster picture. Both came to symbolize Hollywood's contribution to national culture during the Great Depression that followed the stock market crash of 1929. Gangster films like *The Public Enemy* (1931), directed by William Wellman, and *Scarface* (1932), directed by Howard Hawks, dramatized the violence and disorder that accompanied the illegal manufacture and sale of alcoholic beverages during the prohibition era (1919-1933). Such musicals as *Gold Diggers of 1933* (1933) portrayed a spirit of cooperation and optimism intended to combat the economic depression. The film was one of many Hollywood musicals in the 1930's that featured spectacular dance sequences created by Busby Berkeley.

The Great Depression had a strong impact on the American film industry. Interest in sound pictures had nearly doubled annual movie theater attendance in the late 1920's. But the economic crisis greatly reduced attendance, causing many theaters to close. Nearly all the movie companies lost money, and several declared bankruptcy. No major studios shut down, however.

By the mid-1930's, American movie companies again began to prosper. They launched what many consider one of the greatest periods of popular entertainment filmmaking. During the middle and late 1930's, Hollywood produced major hits in nearly all the familiar genres. In particular, the horror film gained new prominence and the sound comedy emerged as a leading film style. The horror cycle actually began in 1931 with *Dracula,* directed by Tod Browning, and *Frankenstein,* directed by James Whale.

Among the comedy films of the 1930's, one of the most popular types was the *screwball comedy.* These movies often portrayed the zany antics of wealthy characters. One classic screwball comedy was *It Happened One Night* (1934), directed by Frank Capra and starring Clark Gable and Claudette Colbert. Another example was *Bringing Up Baby* (1938), directed by Howard Hawks and starring Cary Grant and Katharine Hepburn.

Kobal Collection/SuperStock

Screwball comedies were popular during the 1930's. Many portrayed the zany antics of wealthy characters. Katharine Hepburn and Cary Grant starred in *Bringing Up Baby* (1938).

The arrival of sound gave new emphasis to the role of language in cinema. Many countries strengthened their film industries out of national pride in their language and culture. Some countries restricted the importation of American movies, in order to encourage their domestic film industry. In most countries, the dialogue of foreign films was translated into the home language. In the United States, however, such films were almost always played in their original version, with printed English subtitles projected on the bottom of the film.

The leading film-producing nations of Europe during the silent era, Germany and the Soviet Union, were displaced during the first decade of sound movies by Great Britain and France. Alfred Hitchcock led the emergence of British cinema. Hitchcock directed a number of internationally successful thrillers, including *The Thirty-Nine Steps* (1935) and *The Lady Vanishes* (1938). In France, Jean Renoir made a series of films during the 1930's that shrewdly observed social attitudes of the time, notably

Robert Donat and Madeleine Carroll in a scene from *The Thirty-Nine Steps* (1935); Bettmann Archive

The Thirty-Nine Steps was one of director Alfred Hitchcock's earliest successes. He made the thriller in England in 1935. Hitchcock later settled in the United States. His best English and American suspense films are noted for their humorous touches and their brilliant camerawork.

Culver

Grand Illusion was a classic antiwar film directed by Jean Renoir of France in 1937. The motion picture is set in a German prisoner of war camp for officers in 1917, during World War I.

Grand Illusion (1937) and *Rules of the Game* (1939).

The rise of dictatorships in Germany and the Soviet Union hampered filmmaking in those countries during the 1930's. After Adolf Hitler seized power in Germany in 1933, a number of German filmmakers went into exile. Many settled in the United States. Fritz Lang began an important career as an American film director with *Fury* (1936). Renoir went to Hollywood after the German conquest of France early in World War II (1939-1945). Hitchcock had already left Britain for Hollywood in 1939, though not for political reasons. One German filmmaker who remained in Germany was Leni Riefenstahl. She made two powerful, controversial propaganda films, *Triumph of the Will* (1935), glorifying the Nazi party, and *Olympia* (1938), on the 1936 Olympic Games in Berlin.

The United States did not enter the war until late 1941, and America's prewar period closed triumphantly with two celebrated films. One was *Gone with the Wind* (1939), a Civil War drama directed by Victor Fleming and starring Clark Gable and Vivien Leigh. The other was *Citizen Kane* (1941). A young American director and actor named Orson Welles produced, directed, and starred in this story of a powerful American newspaper publisher. Welles and his cinematographer, Gregg Toland, experimented with startling camera angles and dramatic lighting. The film's brilliant photography helped make it one of the most honored films in cinema history.

Movies and World War II. The role of movies in education and propaganda was far more appreciated during World War II than in World War I. Hollywood contributed to the war effort through traditional entertainment movies and through government service. Fiction films like *Casablanca* (1942) dramatized the war struggle using the traditional screen narrative devices of a love story and individual heroism. The film, directed by Michael Curtiz and starring Humphrey Bogart and Ingrid Bergman, became one of the most popular motion pictures in American film history.

American directors such as John Ford, William Wyler, John Huston, and George Stevens entered military service and produced important documentary films about the war. Working for the U.S. Army Signal Corps, Frank Capra supervised the "Why We Fight" documentary series, which explained American war aims.

Postwar realism. The impact of the war led many European directors to make movies that focused on society and its problems. This impulse resulted in the emergence of the first important postwar European film movement, *neorealism.* Neorealist directors were concerned primarily with portraying the daily life of ordinary people. They mainly filmed on location rather than on a studio set, and they used mostly nonprofessional actors and actresses. These qualities gave neorealist films a gritty, almost documentary look.

Italian director Roberto Rossellini made the first internationally significant neorealist films. Rossellini's *Open City* (1945) and *Paisan* (1946) told of the struggle to liberate wartime Italy from its own Fascist government and the later German occupation of the country. Probably the most famous of the neorealist films was *The Bicycle Thieves* (1948), directed by Vittorio de Sica. It follows a workingman and his young son as they search for a stolen bicycle. The Italian government regarded the treatment of social problems in these films as harmful to the country's image internationally and passed a law in 1949 hampering their export. The law effectively ended the neorealism movement in Italy.

Bettmann Archive

Orson Welles produced, directed, and starred in *Citizen Kane* (1941). This biography of a powerful newspaper publisher is famous for its experimental photographic effects.

Scene from *The Bicycle Thieves* (1949), directed by Vittorio De Sica; Culver Pictures

Italian films gained international attention after World War II with such realistic movies as *The Bicycle Thieves.* The film concerned a man and his son searching for a stolen bicycle.

Thanks to the international impact of neorealism, films and filmmakers previously little known outside their home countries began to gain international recognition. Some of this acclaim resulted from screenings at film festivals. Japanese director Akira Kurosawa brought attention to his country's distinguished film tradition with *Rashomon* (1950). The Latin-American film industry gained recognition with *Los Olvidados* (1950), made in Mexico by Spanish director Luis Buñuel.

Postwar American movies. Like European filmmakers, many American directors entered the postwar era with a desire to make films that were socially relevant. But political, legal, and economic influences led Hollywood to fall back on familiar genres. The conservative political atmosphere of the postwar years discouraged filmmakers from taking risks in subject matter. In 1948, the U.S. Supreme Court effectively banned vertical integration by requiring studios to rid themselves of their theaters, thus eliminating studio control of movie exhibitions. The studio system suffered from that court ruling and declining film attendance in the early 1950's due to the increasing popularity of television. Studios never regained the power they once had.

Year after year during the 1950's, movie attendance steadily decreased. There was a brief upswing in 1953 and 1954 when the industry introduced wide-screen processes such as CinemaScope and Cinerama. These processes temporarily lured the curious away from their television sets. Still, Hollywood's production volume fell from about 550 films per year before World War II to about 250 a year during the 1950's. Independent production began to take over from the studio system, though studios still functioned as distributors. International coproductions became common, mingling stars from many countries.

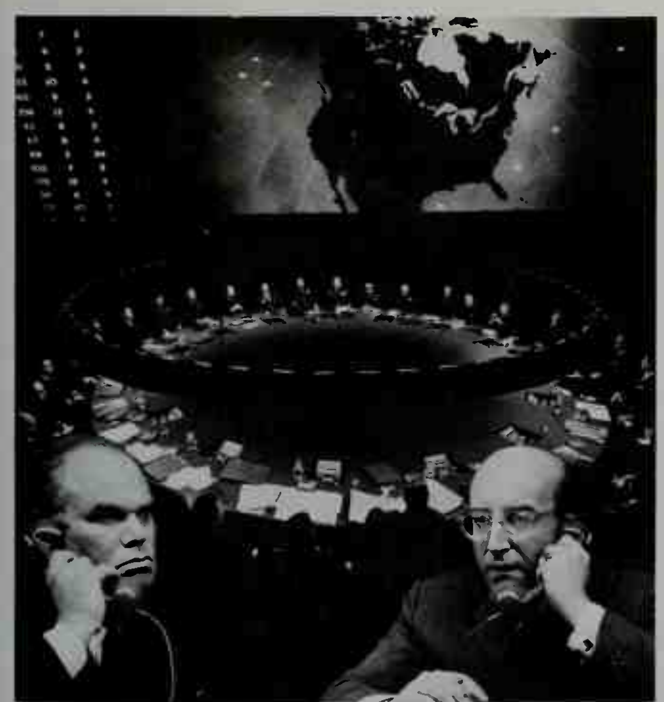
The art film revival. The reduction in Hollywood film production created renewed interest in art films, much as in the 1920's. During the 1950's, a number of theaters in the United States specialized in showing films by foreign directors. Serious filmgoers sought out works by such directors as Federico Fellini of Italy and Ingmar Bergman of Sweden. Fellini became known for such highly personal comedy-dramas as *La Strada* (1954) and *Nights of Cabiria* (1957). Bergman won fame for such brooding and symbolic dramas as *The Seventh Seal* and *Wild Strawberries* (both 1957). Such motion pictures reminded American moviegoers of the possibilities of film art—at a time when many people saw Hollywood as a place dominated by gimmicks and old, overworked formulas.

The New Wave in France. One place where the Hollywood movie remained appreciated was France. There, young film critics praised John Ford, Howard Hawks, and certain other studio directors for bringing a unique visual style and personal viewpoint to standard genre films. Under the influence of critical writings from France, the artistic qualities of Hollywood films began to be appreciated more than ever before.

The chief goal of the young French critics, however, was to revive what they saw as a stuffy French film industry. Leaving writing for directing, they were to become leaders of the French *New Wave.* Their impact on filmmaking of the 1960's was as profound as that of Italian neorealism several years earlier. Such films as *The 400 Blows* (1959), directed by François Truffaut, and

Max Von Sydow, *right,* in a scene from *The Seventh Seal* (1957); Culver

The Seventh Seal helped make Swedish director Ingmar Bergman one of the most widely discussed directors in motion-picture history. Bergman gained fame for a series of films that combined dramatic photography, sensitive acting, and often obscure philosophical and religious themes.



Jean-Paul Belmondo and Jean Seberg in a scene from *Breathless* (1960); Bettmann Archive

Breathless was one of the first New Wave hits. It was directed by Jean-Luc Godard and based on a story by François Truffaut, who later became a major New Wave director.

Breathless (1960), directed by Jean-Luc Godard, marked the emergence of a new generation of influential movie directors.

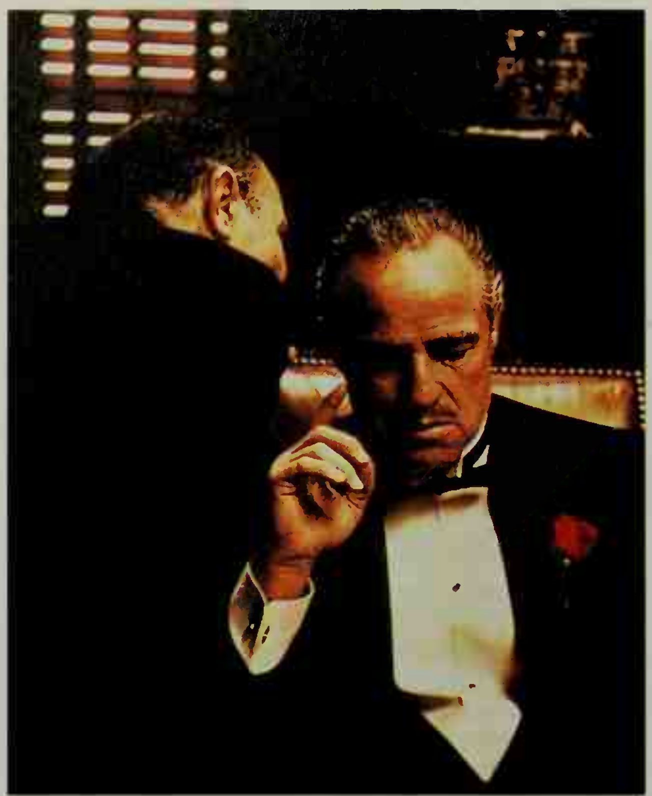
Claude Chabrol is credited with starting the New Wave with *Le Beau Serge* (1958). Louis Malle gained recognition as an important New Wave director with *The Lovers* (1958). Other major directors who emerged from the New Wave included Jacques Rivette and Eric Rohmer.

The years 1959 and 1960 proved to be a key moment in cinema development. Besides the works of Truffaut and Godard, a number of other films showed that a widespread artistic revival was underway. These films included *Hiroshima, Mon Amour* (1959), a French film directed by Alain Resnais; Fellini's *La Dolce Vita* (1960); and Alfred Hitchcock's *Psycho* (1960).

Peter Bull, *left*, and Peter Sellers, *right*, in a scene from *Dr. Strangelove* (1964); Granger Collection

Dr. Strangelove was a 1964 film that created controversy because it took a comic and satirical view of the possibility of a nuclear war between the United States and the Soviet Union.

Movies in the 1960's. The decade of the 1960's saw the appearance of *Cinema Novo* in Brazil, a movement that resembled neorealism. It attempted to combine political subject matter with bold cinema techniques. Such directors as Nagisa Oshima in Japan and Bernardo Bertolucci in Italy became part of the international film scene. Stanley Kubrick, an American director working in England, made a number of popular and influential films. The best known was *Dr. Strangelove or: How I Learned to Stop Worrying and Love the Bomb* (1964). The film is a dark comedy that satirizes the serious subjects of conflict between the United States and the Soviet Union and the threat of nuclear destruction. Kubrick also directed *2001: A Space Odyssey* (1968), a science-fiction work about future space travel and humanity's self-renewal.



During the 1960's, Eastern European films made their mark on the world scene for the first time. Polish director Roman Polanski's *Knife in the Water* (1962) was the first major international success from Eastern Europe. Czechoslovak cinema soon captured worldwide attention with a series of comic films that criticized social and political conditions. The best known included *Loves of a Blonde* (1965) and *The Firemen's Ball* (1967), directed by Milos Forman; and *Closely Watched Trains* (1966), directed by Jiri Menzel. These movies were popular with audiences but not with government officials, and the movement ended when Soviet troops invaded Czechoslovakia in 1968.

Several Eastern European filmmakers, including Polanski and Forman, emigrated to Hollywood, where they could pursue their craft with greater artistic freedom. Forman won the 1975 Academy Award as best director for *One Flew Over the Cuckoo's Nest.*

For several reasons, the American film industry did not fully participate in the world cinema renaissance of the 1960's. Theater attendance continued to suffer in the United States from the availability on television of both old and more recent films, as well as made-for-TV movies. Traditional methods and higher production costs slowed the Hollywood studios' response to new trends and younger talents. Only in the late 1960's did opportunities open up for a new generation of filmmakers. Their impact began to be felt in the 1970's, stimulated by new ways in which motion pictures were marketed to the public.

Changes in Hollywood. For many years, movies were released slowly, first in a few big cities, then fanning out across the country to smaller cities and towns. In the early 1970's, the movie companies discovered that they might gain greater financial returns by releasing a film in hundreds of cities at the same time, supported by national television advertising.

The new distribution method was used experimentally on director Francis Ford Coppola's *The Godfather* (1972), a much-anticipated film based on a best-selling novel about organized crime. The results were impressive. *The Godfather* became the most commercially successful film produced to that time—dethroning *Gone with the Wind,* which had reigned as box-office champion for more than 30 years. In addition, Coppola was the first of Hollywood's younger directors to make a

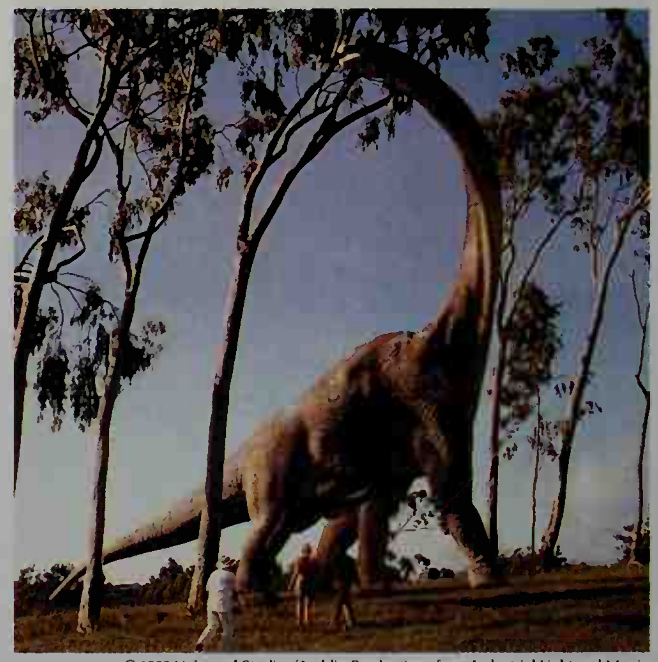
The Godfather was a dramatic account of two generations of a family in the United States who live by organized crime. The motion picture set box-office records in the early 1970's.

major impact. His success helped open the door for other young filmmakers.

A new generation of filmmakers surfaced in the 1970's. Steven Spielberg and George Lucas became the most successful of them. They established a remarkable record for producing and directing popular films, beginning with *Jaws* (1975), directed by Spielberg. Lucas's science-fiction movie *Star Wars* (1977) was the first of many popular adventure, military, and science-fiction movies to come from Hollywood in the late 1900's.



Spielberg and Lucas succeeded with old-fashioned genre movies modernized with spectacular visual effects. Lucas created three more films in the *Star Wars* series, *The Empire Strikes Back* (1980), *Return of the Jedi* (1983), and *Star Wars: Episode 1—The Phantom Menace* (1999). Spielberg and Lucas teamed up to make three films that re-created the daredevil adventures of action movies of the 1930's and 1940's. Lucas produced and Spielberg directed the adventure movies *Raiders of the Lost Ark* (1981), *Indiana Jones and the Temple of Doom* (1984), and *Indiana Jones and the Last Crusade* (1989). As co-producer and director, Spielberg made one of the most commercially successful films in history, *E.T.: The Extra-Terrestrial* (1982), as well as such critical successes as *Schindler's List* (1993) and *Saving Private Ryan* (1998).

The gap grew wider between Hollywood's emphasis on blockbuster hits and the more modest resources and goals of moviemakers from other countries. From Asia, Africa, the Middle East, Australia, and elsewhere, came films whose visions of history, culture, and social relations were little known to audiences in other countries. Examples include *My Brilliant Career* (1980) from Australia and *The Official Story* (1985) from Argentina.

The ability of films from distant places to find audiences in North America also encouraged some American moviemakers to work outside the big-budget, commercially oriented Hollywood film industry. Perhaps the most important non-Hollywood director was Woody Allen. He aimed his comedies at adult, urban moviegoers, and achieved considerable success with such films as *Annie Hall* (1977) and *Hannah and Her Sisters* (1986). Spike Lee became a leading black voice in American cinema with *School Daze* (1988), *Do the Right Thing* (1989), *Jungle Fever* (1991), and *Malcolm X* (1992). Other important independent directors included the brothers Ethan and Joel Coen, who directed *Fargo* (1996); John Sayles, director of *Lone Star* (1996); and Quentin Tarantino, who created *Pulp Fiction* (1994).

During the 1980's and 1990's, motion pictures continued to be pulled between the two poles that influenced their development throughout the 1900's: the small-budget art film and the big-budget, mass-audience movie. New means of distribution—particularly cable TV and videocassettes—helped foster filmmaking throughout the world, resulting in an increased variety of national and cultural viewpoints in film. At the same time, Hollywood continued to exert its powerful attraction on both foreign and American independent moviemakers for its financial resources and access to a vast audience.

The computer revolution. During the 1990's, Hollywood introduced special effects images created by computer graphics, which made possible greater realism and even more elaborate fantasy stories. Steven Spielberg made dinosaurs come to life in present-day settings in *Jurassic Park* (1993) and its sequel, *The Lost World* (1997). An alien attack on Earth was portrayed in *Independence Day* (1996). *Men in Black* (1997) was a popular science-fiction comedy about special agents who hunt alien creatures from other worlds. Such films were

© 1993 Universal Studios/Amblin Productions from Industrial Light and Magic

Jurassic Park, a 1993 science-fiction thriller directed by Steven Spielberg, was noted for its special effects. The film tells of a theme park featuring genetically reproduced dinosaurs.

Fox/Paramount from Shooting Star

Titanic became the biggest box-office hit in motion-picture history, earning more than $600 million. The 1997 film portrays the first voyage of the famous British ocean liner, which struck an iceberg in the North Atlantic Ocean in 1912 and sank. *Titanic* won several Academy Awards.

sometimes criticized for allowing special effects to replace story elements, such as characterization and plot. Computer special effects contributed to the success of *Titanic* (1997). The movie portrayed the famous 1912 sinking of a luxury ocean liner and broke box-office records throughout the world.

Computer animation and special effects reached new heights in such films as *Toy Story* (1995), *The Matrix* (1999), *Gladiator* (2000), and *The Perfect Storm* (2000). In the early 2000's, several fantasy movies became huge international hits. They included *Harry Potter and the Sorcerer's Stone* (2001), *The Lord of the Rings: The Fellowship of the Ring* (2001), and *Spider-Man* (2002).

Motion sickness is a condition in which motion causes extreme nausea. The sufferer becomes pale and perspires. If the motion persists, he or she vomits. Many people affected by motion sickness also experience belching, headaches, apathy, and sleepiness.

Motion sickness occurs in response to the movements of ships, automobiles, buses, trains, aircraft, and spacecraft. It may be called seasickness, carsickness, trainsickness, or airsickness, depending on the source of the motion. More than half the astronauts and cosmonauts who have flown in large spacecraft have experienced a type of motion sickness called *space adaptation syndrome.* Aboard spacecraft, as aboard ships, motion sickness usually appears during the first day of travel. It generally disappears after a few days, as the traveler gets used to the motion.

Motion sickness typically results from the effects of unusual motion on a person's *vestibular system,* the organs of balance in the inner ear (see **Ear** [The sense of balance]). Motions that cause sickness exceed the limits that the vestibular system can accurately report to the brain. In such cases, the vestibular system reports false information about bodily motions that conflicts with information reported by vision and the other senses. For example, the vestibular system might report that the body is moving upward, while the person's eyes report that the body is moving downward. People or animals that lack the vestibular system are immune to motion sickness.

Research has shown that the vestibular system, in addition to its role in balance, functions as part of the body's mechanism for detecting poisons. When certain poisons are present in a person's blood, the vestibular system malfunctions and reports false information. After receiving this false information, the brain causes vomiting, which empties the person's stomach of the poison before more of it can be absorbed into the bloodstream. Research suggests that motion sickness occurs when the brain interprets the false information from the vestibular system as being the result of poisoning. The brain then triggers vomiting as the appropriate action.

To help avoid or reduce motion sickness, a person should keep head movements to a minimum—by holding the head against a headrest, for example—and look at the distant horizon straight ahead. These actions prevent conflict between the motion information reported by the eyes and the vestibular organs. In addition, certain drugs help prevent motion sickness if taken before traveling. Some professional pilots with recurrent motion sickness have used biofeedback training to learn to control such body functions as heart rate and skin temperature (see **Biofeedback**). For reasons not yet understood, voluntary control of such functions during exposure to motion situations can help control the symptoms of motion sickness. K. E. Money

Motivation commonly refers to anything that causes people to behave as they do. Most people have a clear sense of what it feels like to be motivated to do something. But scientists have found it difficult to define motivation. When studying motivation, most psychologists and behavioral scientists focus on two specific aspects of motivated behavior—the arousal of behavior and the direction of behavior.

Arousal of behavior involves whatever brings an organism to action. Arousal means being "stirred up" or "ready for action." It may result from stimuli inside or outside the body. Inside, or internal, stimuli include the sensation of dryness that produces thirst and the stomach contractions that cause hunger pangs. Outside, or external, stimuli include the heat that causes pain when a person touches a hot burner.

An aroused organism's response to stimuli depends on habits and other ways of acting that it has learned. Based on such learning, the organism may act either aimlessly or highly purposefully in a particular situation.

Direction of behavior is determined by several influences. These influences include an organism's habits, skills, and basic capacities.

Motives themselves may also direct behavior. For example, differing motives may direct the behavior of two football coaches when their teams face much stronger opponents. One coach's behavior may be motivated by—that is, directed toward—competition or winning. That coach may concentrate on seeking an upset victory. However, the behavior of the other coach may be motivated by the players' feelings and may focus on keeping the players from being discouraged by the probable loss.

Physiological conditions can direct behavior by making organisms sensitive to stimuli from the environment. For example, many types of birds may become sensitive to available mates and also direct their behavior toward nest building when the birds' hormones reach a certain level.

Kinds of motives. Most behavioral scientists place all motives into one or more of three groups. These groups are (1) homeostatic motives, (2) nonhomeostatic motives, and (3) learned, or social, motives.

Homeostatic motives include hunger, thirst, respiration, and excretion. They work to keep the body in a balanced internal state. The term *homeostasis* refers to the body's tendency to maintain such a balanced internal state. Many homeostatic motives are set in motion either by bodily deficits or bodily excesses. When the body needs water, for example, changes occur that cause thirst and motivate the person to seek something to drink.

Nonhomeostatic motives include sex, such maternal activity as nest building, and curiosity about the environment. These motives are aroused by occasional forces. In the absence of such forces, nonhomeostatic motives may be inactive. In contrast, the needs for food, water, and air—homeostatic motives—have almost continuous influence.

Learned motives, or *social motives,* include curiosity, a desire for novelty, and needs for such things as achievement, power, social affiliation, and approval. These motives seem to develop through experience, especially through social experience, such as early experience in the family or with friends during adolescence. Learned motives continue to evolve and influence behavior throughout life. However, their exact origins are not clear. Some babies have strong needs for social affiliation that may result from conditions during pregnancy and birth as well as, perhaps, other factors.

The three kinds of motives often overlap. For example, desire for new experiences may be homeostatic as well as learned. This is because people differ as to the level of novel stimulation their homeostatic mechanisms seek to maintain. As a result, some people always seem to be looking for something new while others seem overly content with the familiar.

Theories of motivation. Some general theories of motivation identify a limited number of central motives, such as sex and death instincts, from which other motives develop. Other theories support a single, main motive in human development, such as a person's need for power or to fully realize his or her potential.

In contrast, some psychologists argue that many different motives guide behavior. These motives include needs for order, understanding, and independence. Other theories of motivation try to identify the physiological mechanisms underlying a wide range of motives. For example, researchers exploring the relations between behavior and brain function have identified chemical and electrical processes in the brain that influence behavior in people and animals.

Applications. Motivation plays an important role in informal relationships, but also in highly structured relationships, such as those found in industry and education. In industry, managers use motivation techniques to promote cooperation between employers and employees. Such cooperation enables employees to satisfy certain needs through their jobs, including security, career interests, and respect. If employees expect their jobs to help satisfy these needs, they will probably be more motivated to achieve the company's business objectives.

In education, teachers often use rewards to motivate students to learn. They may also motivate students to find satisfaction in the learning activity itself by emphasizing the value of being able to work through problems. Such an approach encourages students' mastery of problem-solving techniques and an increased expectancy of success in future tasks. Edwin B. Fisher, Jr.

Motivation research tries to learn why people choose things they buy. It also seeks to find out what people learn from advertising. Motivation researchers explore the feelings and points of view of consumers. They use knowledge from psychology, sociology, and other social sciences to interpret these emotions and attitudes. Motivation researchers interview people in a conversational way, and sometimes give them tests that must be analyzed by psychologists and sociologists. This type of research has shown that people do not shop with only price and quality in mind. They may buy something to impress others, or to keep up with their group. People may also buy something to imitate someone they admire. Bonnie B. Reece

Motmot, *MAHT maht,* is the name of a family of birds related to kingfishers. Motmots live in Central and South America. In most, the tail feathers wear off easily and the end of the tail looks like two tennis rackets. The bird swings its tail from side to side when it is perched, perhaps because predators are likely to spring at the moving tail, rather than at the motionless bird.

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd

Motmot

Motmots have handsome feathers colored blue, black, green, and cinnamon. The birds range from 6 ½ to 20 inches (17 to 51 centimeters) long. Motmots like to live alone, usually in gloomy forests. Some nest in rock crevices, but most nest in tunnels they bore in river banks or in the ground. The female lays three or four eggs. Motmots eat insects, reptiles, and fruit. The motmot has a *serrated* (saw-edged) bill.

Scientific classification. Motmots belong to the motmot family, Momotidae. David M. Niles

Moton, *MOHT uhn,* **Robert Russa,** *RUHS uh* (1867-1940), was an African American educator. He served as principal (later called *president*) of Tuskegee Institute from 1915 to 1935 (see **Tuskegee University**). Moton also was an advisor on race-related issues to United States Presidents Woodrow Wilson, Warren G. Harding, Calvin Coolidge, Herbert C. Hoover, and Franklin D. Roosevelt. At Wilson's request, Moton went to France in 1918 to study conditions affecting black soldiers in World War I. He served in 1930 as chairman of the U.S. Commission on Education in Haiti. Moton wrote several books, including *Racial Good Will* (1916), *What the Negro Thinks* (1929), and his autobiography, *Finding a Way Out* (1920).

Moton was born in Amelia County, Virginia. He graduated from Hampton Institute. Moton served as president of the National Negro Business League (now the National Business League) from 1921 to 1930.

Motorboat racing is an exciting, competitive sport that tests the performance of motorboats and the skill of drivers. Every year, thousands of people compete in a variety of motorboat races. Racing categories are based on such factors as the size of the boat, the shape of its hull, and the location and power of its engine.

Motorboat races are held throughout the year on lakes, rivers, and oceans in many parts of the world. In the United States, most events are sanctioned and approved by the American Power Boat Association (APBA). Founded in 1903, the APBA sanctions races, establishes rules of competition, and conducts speed trials. It also jointly sanctions races with the Canadian Boating Federation. The APBA is the national authority for the Union of International Motorboating (UIM). As the world governing body for powerboat racing, the UIM governs international competition and is the official authority for world speed records.

Racing boat designs

Racing boats differ from recreational boats in design and equipment. Most recreational boats use standard marine engines designed for safe, dependable performance. The hull may vary in length from 9 to 100 feet (2.7 to 30 meters). Racing engines and hulls are specially designed for speed, endurance, and handling. Racing boat lengths range from 9 to 50 feet (2.7 to 15 meters).

Hull designs. Racing boats have two basic hull designs—*displacement* and *planing.* Motorboats with displacement hulls ride in the water. Those with planing hulls skim over the water's surface on a cushion of air.

Most motorboats with displacement hulls are known as *flatbottoms.* These boats have flat bottoms with gently sloped sides and range from 9 to 17 feet (2.7 to 5.2 meters) long. Flatbottoms may have inboard or outboard engines. Inboard engines are inside the hull. Outboard engines are outside, usually at the rear of the boat. Flatbottoms with outboard engines are called *runabouts.* The driver of a flatbottom is in front of the engine. The driver sits in inboards or kneels in most outboards.

Hydroplanes are the most common planing boats. They have flat or only slightly curved bottoms and hulls. This design allows the pressure of the water to lift the boat and keep it on the surface of the water as long as the boat moves rapidly. A short float called a *sponson* on each side of the hull helps lift the boat's front end as it increases speed. Some hydroplanes can reach speeds up to 200 miles (320 kilometers) per hour. However, they require much room to make turns. The driver usually sits in front of the engine. However, in some inboards the driver sits behind the engine. Hydroplanes range from 11 to 28 feet (3.4 to 8.5 meters) long.

Other racing boats may have a V-bottom hull or a tunnel hull. A V-bottom hull has steeply slanted sides and a pointed bottom. Motorboats with this hull perform well in rough water. They range from 17 to 50 feet (5.2 to 15 meters) long. Tunnel-hulled boats are similar to hydroplanes in that they ride on a cushion of air. But a tunnel hull has sponsons that extend the length of the boat, creating a "tunnel" down the middle of the boat.

Engine designs. Racing motorboats are powered by gasoline, diesel, jet, or turbine engines. Most boats operate with a single engine. However, some oceangoing boats may have as many as four engines.

Some racing categories require *stock engines,* which are made in a factory and are not allowed to be *modified* (changed). Other racing classes allow modification of the motor.

In most races, inboard racing boats must use standard automobile engines. But large inboard hydroplanes may also use aircraft engines. Outboard motorboats use only marine engines. Many manufacturers produce marine models designed for high performance.

The propeller is one of the most important pieces of equipment on a racing boat. Propellers are designed to

increase the boat's speed and to provide efficient handling. They may have two, three, or four blades.

Safety equipment is required for all motorboat racing. All drivers must wear approved helmets and life jackets. Some life jackets are fitted with special collars to prevent neck injuries. In addition, most boats have a "kill switch" that is designed to protect drivers who get thrown from their boats. The switch attaches to the driver's life jacket. The engine automatically shuts off if the switch becomes detached from the jacket while the motor is running. This precaution protects drivers from being injured by their boats if they fall into the water. Oceangoing boats must have fire extinguishers and first-aid kits. Some hydroplanes carry an oxygen supply for the driver as an added safety precaution.

Types of racing

The APBA formulates rules and conducts races in 10 categories: (1) stock, (2) modified, (3) professional, (4) outboard performance craft, (5) inboard, (6) inboard endurance, (7) unlimited, (8) offshore, (9) drag, and (10) R/C model. Each racing category is divided into classes based on engine and hull specifications.

There are four basic kinds of motorboat races: (1) circle, or closed course, (2) endurance, (3) drag, and (4) offshore. Circle racing is open to most classes of motorboats and takes place on circular or oval courses of varying lengths. Endurance races also cover oval courses. In many endurance races, drivers complete as many laps of the course as possible within a specific amount of time. Time limits range from 10 minutes to more than 7 hours. Boats that are designed for drag racing compete on short, straight courses. This type of race emphasizes the boat's ability to accelerate quickly. Most offshore races are held in ocean waters. Some of the larger offshore boats may race distances of more than 200 miles (320 kilometers). Hydroplanes are generally raced in circle competition, while flatbottoms compete both in circle and drag racing. Boats with V-bottom hulls are used primarily in offshore and endurance races.

About 3,000 drivers compete in nearly 300 APBA events each year. Many members also serve as referees, inspectors, and scorers. The Gold Cup, the APBA's most important hydroplane race, was first held on the Hudson River in 1904. It is raced by unlimited hydroplanes over a 2- or $2\frac{1}{2}$-mile (3.2- or 4-kilometer) circular course.

Motorcycle is a two- or three-wheeled vehicle powered by a gasoline engine mounted midway between the front and rear wheels. A motorcycle has a much heavier and stronger frame than a bicycle, the vehicle from which it was developed. People in many parts of the world use motorcycles for transportation or ride them for recreation and sport. Many police departments use motorcycles for pursuit and traffic control because these vehicles can be maneuvered easily through traffic. Some fire departments use motorcycles to transport medical personnel to accident scenes. Many motorcyclists call their machines "bikes."

In most countries, motor vehicle laws affect the operation of motorcycles as well as of automobiles and other

Motorcycles can be used for both recreation and transportation. For some riders, a motorcycle offers the thrill of competing in races. For others, it helps in performing a job. Messengers and police officers value the "bike" for its ability to maneuver easily through traffic.

kinds of vehicles. Many countries require cyclists to have a motorcycle operator's license, for which a person must pass a test. Neither the United States nor Canada has a national requirement, but most states and provinces require licenses. One test used by many U.S. licensing agencies is the Motorcycle Operator Skills Test (MOST). To pass this test, cyclists must demonstrate skill in handling a motorcycle. Many states and provinces, as well as many countries, require cyclists to wear safety helmets and protection for their eyes.

Motorcycling is popular throughout the world. In regions where gasoline is usually more expensive, such as East Asia, Europe, and South America, motorcycles are regarded as convenient and inexpensive transportation. In the United States and Canada, motorcycles are widely used for recreation, as well as for transportation to jobs. In urban areas, motorcycles help to reduce traffic congestion and air pollution.

Kinds of motorcycles. Manufacturers produce motorcycles in a variety of sizes, types, and weights. The two main kinds are (1) those designed primarily for use on streets and other paved surfaces, and (2) those intended chiefly for off-road riding. The first group consists of street and touring bikes and motor scooters. The second group includes trail bikes and a variety of other related off-road vehicles.

Street bikes are used on roads and highways for short or long trips and for in-town riding. They weigh from 235 to 500 pounds (110 to 230 kilograms) and can travel at all legal highway speeds.

Touring bikes are street bikes that carry special equipment for long-distance travel. For example, many touring bikes are equipped with windshields to provide extra protection against the wind, and compartments to carry luggage. Touring bikes weigh from 500 to 900 pounds (230 to 410 kilograms) and enable riders to travel long distances more comfortably than they could on street bikes.

Trail bikes can travel on rough country trails, climb hills, and cross streams. They have deeply grooved tires that provide traction on gravel and other rough surfaces. They weigh from 150 to 250 pounds (68 to 110 kilograms).

Motor scooters are primarily designed for use at lower speeds in urban settings. The driver of a motor scooter sits with both feet on a floorboard.

Minibikes and minicycles have motorcycle-type engines but weigh less and are more compact than most motorcycles. They are not built for use on paved roads.

Motorbikes include mopeds (pronounced *MOH pehdz*), which are started by pedaling. Mopeds have an automatic transmission, and can reach a speed of 30 miles (48 kilometers) per hour.

The parts of a motorcycle. A motorcycle has five major parts: (1) the engine, (2) the transmission system, (3) the wheels, (4) the brakes, and (5) the controls. A frame of steel or chrome tubing holds them together.

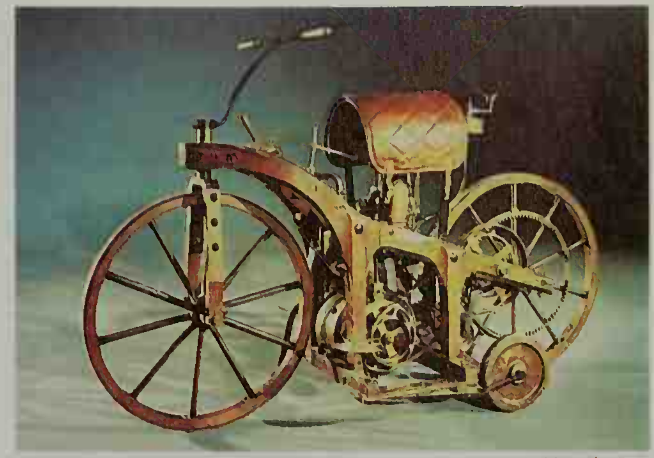
The engine of a motorcycle has one to six cylinders. It operates on either a two-stroke or four-stroke cycle (see **Gasoline engine** [Cycle]).

The transmission system of most motorcycles consists of four, five, or six gears. Racing models may have as many as eight speeds, and some small models have as few as two.

The wheels. Most street motorcycles have steel- or aluminum-rimmed wheels with tubeless tires similar to those on automobiles. However, many off-road bikes have rubber tubes inside the tire to hold compressed air. Motorcycle tires have a rounded tread pattern that provides the traction needed for leaning through turns. The *front forks,* an extension of the frame, help hold the front wheel in place. They serve as a suspension system

that cushions the rider against bumps. A *rear swing arm* allows the rear wheel to move up and down, providing additional stability when riding over bumps.

The brakes. A motorcycle has front- and rear-wheel brakes, which work separately. The front brake supplies most of the stopping force.



The controls. The rider uses various hand and foot controls to operate the motorcycle. Most modern bikes have an electric starter. A hand twist grip controls the throttle, which regulates the engine speed. A hand lever on the left handlebar operates the clutch. A hand lever on the right handlebar controls the front brake, and a foot pedal controls the rear brake. Most motorcycles have a second foot control for shifting gears.

Motorcycle safety. Organizations in many countries have programs that promote motorcycle safety. The Motorcycle Safety Foundation in the United States and the Canada Safety Council have developed motorcycle safety courses. These courses, which are offered by many community colleges, high schools, and police departments, are designed to develop good riding habits. They also stress the importance of proper cycling clothes, such as a helmet, goggles, gloves, and boots.

Motorcycling as a sport enables riders to compete in such events as dirt-track races, *enduros* (endurance races), and *motocross* races. Motocross racing is the most popular type of motorcycle competition. It includes races run on rugged courses that have jumps, hills, and other obstacles.

The Fédération Internationale de Motocyclisme governs motorcycle competition at world level. The federation, which has headquarters in Mies, Switzerland, includes more than 80 national affiliates. The U.S. affiliate, the American Motorcyclist Association, governs most motorcycle competition in the United States. It has headquarters in Pickerington, Ohio. The AMA *sanctions* (approves) a number of annual races. A point system established by the AMA determines a racing champion each year. Cyclists receive points for winning official races or for placing high in the events. The racer who earns the most points becomes Grand National Champion.

neer. He attached a four-stroke piston engine to a wooden bicycle frame. For the next few years, motorcycles remained largely experimental. During the early 1900's, they developed into useful vehicles. Today's motorcycles have the same general appearance as earlier models. But modern bikes are easier to handle, and they have stronger frames, more powerful engines, and more efficient brakes. Gregory B. Harrison

Mott, Lucretia Coffin, *loo KREE shuh* (1793-1880), was a leader of the abolitionist and women's rights movements in the United States. Mott helped establish two antislavery groups, and she and Elizabeth Cady Stanton, another reformer, organized the nation's first women's rights meeting.

Mott was born in Nantucket, Massachusetts. Her family were Quakers, and she taught at a Quaker school near Poughkeepsie, New York, in 1808 and 1809. She moved to Philadelphia in 1809. Mott became a Quaker minister in 1821 and, like many other Quakers, was active in the abolitionist movement. She became known for her eloquent speeches against slavery. In 1833, Mott helped found the American Anti-Slavery Society and the Philadelphia Female Anti-Slavery Society. She helped organize the Anti-Slavery Convention of American Women in 1837.

Detail of a portrait by Joseph Kyle, from the collection of Mrs. Alan Valentine (R. E. Condit)

Lucretia Mott

In 1840, Mott went to London as a delegate to the World Anti-Slavery Convention. However, the men who controlled the meeting refused to seat her and the other women delegates. Mott met Stanton, who was attending the meeting with her husband. The two women were angered by the convention's action and pledged to work for women's rights.

In 1848, Mott and Stanton called a women's rights convention in Seneca Falls, New York, where the Stantons lived. The men and women at this meeting passed a Declaration of Sentiments. This series of resolutions demanded more rights for women, including better educational and job opportunities and the right to vote.

After 1848, Mott began to speak widely for both abolition and women's rights. She also wrote a book, *Discourse on Woman* (1850). It discussed the economic, educational, and political restrictions on women in the United States and other Western nations. After slavery was abolished in the United States in 1865, Mott supported the movement to give blacks the right to vote. In 1864, she and other Quakers had founded Swarthmore College. June Sochen

Mouflon. See Sheep (Wild sheep).

Mould. See Mold (plant).

Moulting. See Molting.

Moultrie, *MOHL tree* or *MOOL tree,* **William** (1730-1805), was an American military leader during the Revolutionary War in America (1775-1783). Fort Moultrie in the Charleston (South Carolina) harbor was named for Moultrie (see **Fort Moultrie**).

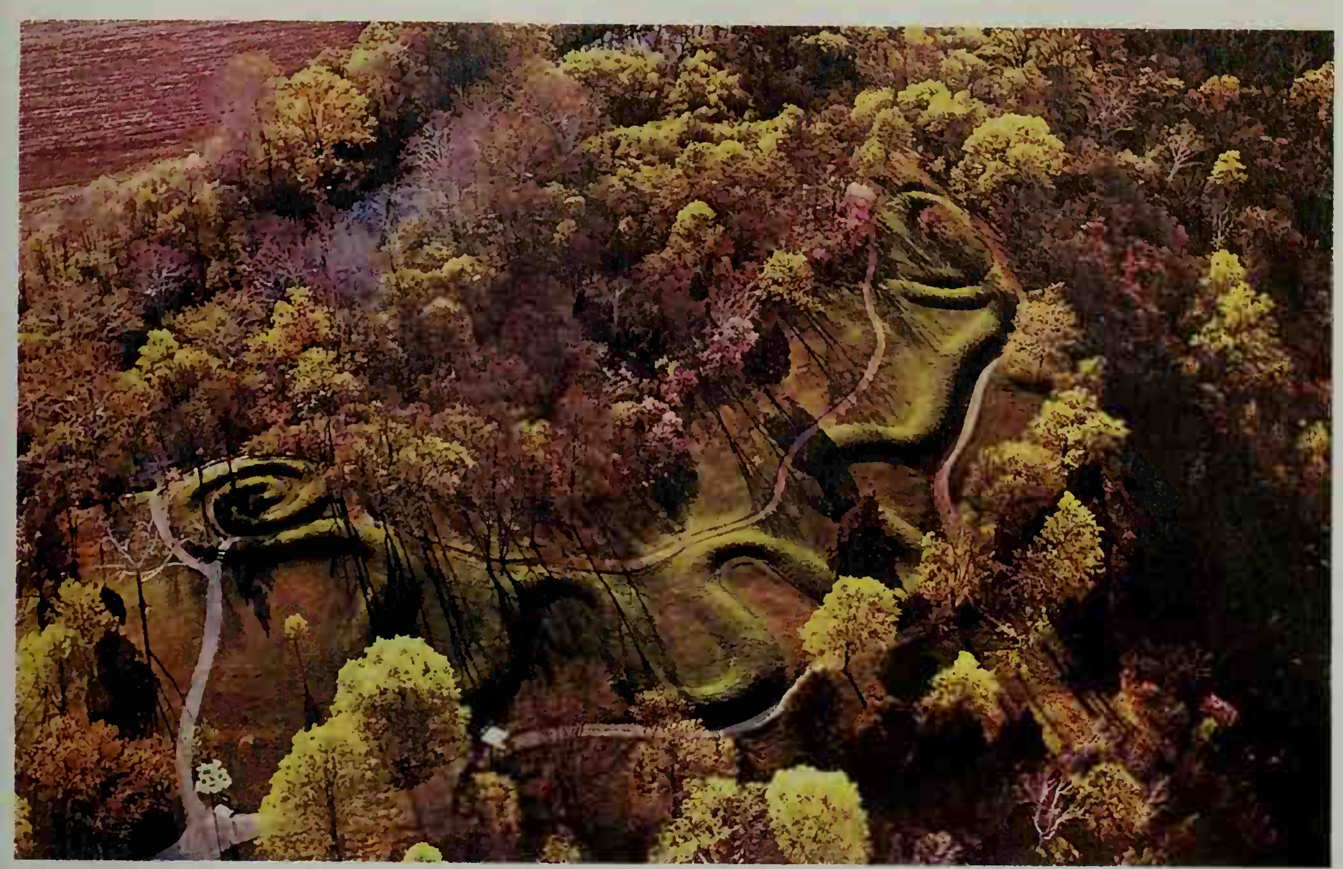
Moultrie entered the Continental Army at the start of the war, and became a brigadier general after his brave defense of Charleston harbor against the British fleet in 1776. He defeated the British again at Beaufort in 1779. Moultrie was captured when Charleston surrendered in 1780. He was set free in a prisoner exchange in 1782 and became a major general.

Moultrie was governor of South Carolina from 1785 to 1787 and again from 1792 to 1794. His *Memoirs of the American Revolution* was published in two volumes in 1802. Moultrie was born in Charleston.

Paul David Nelson

Mound bird is a name applied to several species of birds that build mounds for nests. Mound birds are also called *megapodes.* They are found from the Nicobar Islands in the Indian Ocean to the Philippines and Australia. Mound birds are dull-colored, and most are about the size of a chicken.

Mound birds lay 8 to 10 pinkish eggs in mounds of soil mixed with leaves and other plant material. They scrape the mounds together with their large feet. The plant material gives off heat as it decays. This heat and the heat of the sun hatch the eggs. The birds use the same mounds for many years, adding to them each season. Some mounds become more than 14 feet (4 meters) high and 70 feet (21 meters) in diameter. The female places each egg in a hole that she digs in the top of the mound. The young birds hatch in six weeks.



Bertin W. Anderson

Scientific classification. Mound birds make up the megapode family, Megapodiidae.

M. D. England, ARDEA

A mound bird lays its eggs in mounds of decaying plants. The decaying material releases heat, which hatches the eggs.

© Tony Linck

Great Serpent Mound, near Hillsboro, Ohio, was built by people of the Fort Ancient culture. It resembles a huge snake and measures about $\frac{1}{4}$ mile (0.4 kilometer) long. Its purpose is unknown, but many Indian mounds were used as burial places or as platforms for important buildings.

Mound builders were early North American Indians who built large monuments of earth. They built the mounds as burial places and as platforms to hold temples and the houses of chiefs. Thousands of mounds still stand in Canada and the United States. They were built entirely by workers who carried loads of earth on their backs. The mound builders had no horses or oxen and no wheeled vehicles. Many of the mounds consist of several hundred tons of dirt, stone, and other materials.

People once believed the Indians could not have built such huge structures. They thought the mound builders were a lost people who disappeared from North America before the Indians came. But scientists have found Indian-made objects in the mounds, proving that the builders were Indians. According to another theory, Indians learned mound building from the Vikings, who explored part of the east coast of North America about A.D. 1000. But the Indians began to build mounds at least 7,000 years ago, long before the Vikings arrived.

The mound builders were not a single group of people. Many groups of Indians practiced mound building, especially those who lived in the valleys of the Mississippi and Ohio rivers and in the Great Lakes region. The three main mound-building peoples were the *Adena*, the *Hopewell*, and the *Mississippian*.

The Adena culture began to build large mounds about 700 B.C. in what is now southern Ohio. The people lived in small villages and supported themselves by hunting, fishing, gathering wild plants, and perhaps a little farming. They were skilled at a variety of crafts, such as pottery and jewelry making.

The Adena built mounds as burial places. Many Adena mounds are single heaps of earth, and some have ditches around them. The Adena made these monuments by piling dirt, stones, or other materials over the dead. The size of a mound increased as bodies were added to it. Most of the dead were buried in simple graves in the mounds. However, the bodies of village leaders and other high-ranking people were placed in log tombs before being covered with earth. Such tombs also held a few gifts for the dead person. A common gift was a tobacco pipe made of clay or carved from soft stone. One of the largest Adena burial mounds, Grave Creek Mound in Moundsville, West Virginia, is about 70 feet (20 meters) high. The Adena also built ridges of earth to surround their sacred sites.

The Adena traded with other Indians, and mound building spread to those groups. Mounds similar to those of the Adena were built by prehistoric Indians in several areas, including what are now New York, New Jersey, and Vermont.

The Hopewell culture flourished from about 100 B.C. to about A.D. 500. It extended throughout present-day Ohio, Indiana, Michigan, Illinois, Wisconsin, Iowa, and Missouri. The people cultivated a variety of crops, including corn and squash. Farming enabled Hopewell communities to support more people than the Adena villages did. The Hopewell also developed a vast trade network. Hopewell traders obtained shells and shark teeth from what is now Florida and *pipestone*, a soft stone used to make pipes, from present-day Minnesota. They also got volcanic glass from the Wyoming

An eagle made of rocks spreads across the top of a circular mound near Eatonton, Georgia. It is not known who built this mound, but many mounds in the Southeastern United States were built by Indians who belonged to the Mississippian culture.

area and silver from what is now Ontario. Many of these materials were made into gifts to bury with the dead.

The Hopewell cremated some of their dead and put the ashes in burial mounds. They placed the ashes or the unburned dead in log tombs similar to the ones made by the Adena. The tombs contained many gifts, such as beads, bracelets, pipes, pots, tools, and weapons. The Hopewell believed a person's spirit used these articles in the next world.

The Hopewell built many more mounds than did the Adena. Many Hopewell sites consist of many mounds surrounded by a ridge. The largest site, called the Newark Earthworks, is in Newark, Ohio. It has several large earthen structures, including an octagonal ridge that surrounds about 50 acres (20 hectares) of land.

The Hopewell trade network collapsed by about A.D. 500, and the people no longer built as many earthen mounds. Scholars do not know exactly why the Hopewell culture declined. However, many archaeologists believe that other Indian groups were growing and outbreaks of war were increasing at that time.

The Mississippian culture lasted from about 700 until the 1700's, after the arrival of European settlers. It developed primarily in what became the southern United States and in the Mississippi Valley area. The Mississippian people raised livestock and grew crops. They built some of the earliest cities of North America.

The largest Mississippian city was Cahokia, in present-day Illinois. It had a population of nearly 40,000. Monk's Mound, the largest mound in Cahokia, is bigger at the base than the Great Pyramid of Egypt. Monk's Mound rises about 100 feet (30 meters) and covers about 16 acres (6 hectares). Cahokia had more than 100 other mounds. Many were burial mounds, and others served as foundations for temples or for the houses of city officials.

Monk's Mound, built by the Mississippian peoples, is the largest of over 100 mounds near Cahokia, Illinois. It covers about 16 acres (6 hectares) and is bigger at the base than the Great Pyramid of Egypt.

The Mississippian people adopted many customs from the Indians of what is now Mexico, with whom they may have traded. Like the Indians, the Mississippians built large, flat-topped temple mounds in the center of their cities. At the top of each mound stood one or more temples, where ceremonies were held. Temple mounds still stand in many cities, including Moundville, Alabama; Macon, Georgia; and Winterville, Mississippi.

Many southern Mississippian people practiced a religion that anthropologists call the *Southern Cult*. This cult borrowed many customs and symbols from Mexican Indian religions. For example, much Southern Cult artwork includes a flying human figure that has winglike tattoos around the eyes. Artists also decorated many articles with spiders and woodpeckers, which they believed had special powers. The Indians probably practiced human sacrifice as part of their religion.

The Mississippian civilization continued to grow until the 1500's, when diseases brought by European explorers killed many of the people. Only one Mississippian group, the Natchez Indians, survived long enough to be fully described by the Europeans.

Other mound builders. One of the largest mound sites in the United States is Poverty Point, near Epps, Louisiana. The main part of the site consists of a group of six octagonal terraces, one within the other. The largest octagon has a diameter of about 4,000 feet (1,200 meters). Poverty Point is probably more than 3,000 years old. Many scientists think the people who designed Poverty Point were influenced by the religious monuments of Mexico's Olmec Indians.

In what is now the state of Ohio, descendants of the Hopewell known as the *Fort Ancient culture* built earthen forts and other structures. The name of the culture comes from one of their largest forts, Fort Ancient. The remains of the fort surround over 100 acres (40 hectares) of land on a hill above the Little Miami River, near Lebanon, Ohio. A famous mound built by the Fort Ancient people is the Great Serpent Mound, near Hillsboro, Ohio. It looks like a huge snake from the air and is about $\frac{1}{4}$ mile (0.4 kilometer) long. The mound's purpose is unknown.

Prehistoric Indians in what are now Iowa, Minnesota, and Wisconsin built hundreds of large burial mounds in the shape of birds, bears, panthers, and other animals. A bird mound near Madison, Wisconsin, has a wingspread of more than 600 feet (180 meters). Near Baraboo, Wisconsin, a mound shaped like a standing man measures more than 210 feet (63 meters) from head to toe. Other major mound sites include Lizard Mounds, near Milwaukee, and Effigy Mounds National Monument, near McGregor, Iowa. Dean Snow

Mount Ararat, *AR uh rat,* is a mountain in eastern Turkey near Lake Van. According to Biblical tradition, Noah's Ark landed there after the Great Flood (Genesis 6-8). However, the earliest artifacts archaeologists have discovered on Ararat date from early Christian times, thousands of years after the Great Flood would have occurred. The mountain, also called *Agri Dagi,* is the highest peak in Turkey. Scholars believe that for Biblical writers, Ararat probably symbolized the edge of the known world. The mountain rises 16,849 feet (5,137 meters).

Mount Cook is the highest peak (12,316 feet, or 3,754 meters) in New Zealand. It is in the Southern Alps in Mount Cook National Park, in the central part of New Zealand's South Island. The mountain's Maori name is *Aoraki,* also spelled *Aorangi.* It was named Mount Cook for Captain James Cook, the English navigator who was one of the first Europeans known to have seen it.

W. B. Johnston

See also **Mountain** (diagram: Major mountains); **New Zealand** (picture).

Mount Elbrus, *ehl BROOS,* is the highest mountain in Europe. It rises 18,510 feet (5,642 meters) in the Caucasus Mountains. Mount Elbrus is located in southwestern Russia (see **Russia** [terrain map]). Over 20 glaciers, covering about 55 square miles (142 square kilometers), descend from the mountain. See also **Mountain** (diagram: Major mountains). Leslie Dienes

Mount Etna, *EHT nuh,* is one of the most famous volcanoes in the world. It rises 10,902 feet (3,323 meters) on the eastern coast of the island of Sicily. Part of the mountain's base, which is about 100 miles (160 kilometers) around, extends to the Mediterranean Sea.

Mount Etna (sometimes spelled *Aetna)* makes a color-

AP/Wide World

Mount Etna is one of the world's most famous active volcanoes. It has erupted periodically for thousands of years, sometimes violently. This eruption took place in 2001.

Dave Bartruff, FPG

Mount Everest, in the Himalaya on the frontier of Tibet and Nepal, is the highest mountain in the world. The lofty, snow-covered peak rises about 5 $\frac{1}{2}$ miles (8.9 kilometers) above sea level.

ful picture with its snow-covered peaks, the forests growing on its slopes, and the orchards, vineyards, and orange groves about its base. The region around Etna is the most densely populated area of Sicily. Nearby are the cities of Catania and Acireale, and 63 villages.

Mount Etna has been erupting periodically for thousands of years. Writers of ancient Greece left accounts of Etna's activity. Some of the eruptions have been extremely violent. About 20,000 people were killed in an earthquake that accompanied a 1669 eruption. Several towns were destroyed in 1950 and 1951. Violent eruptions in 1960 ripped a hole in the mountain's east side. Eruptions also occurred several times since then.

Howell C. Lloyd

See also **Mountain** (diagram: Major mountains).

Mount Everest is the highest mountain in the world. It rises about 5 $\frac{1}{2}$ miles (8.9 kilometers) above sea level. It is one of the mountains that make up the Himalaya, on the frontiers of Tibet and Nepal, north of India (see **Nepal** [map]).

The official height of Mount Everest is 29,035 feet (8,850 meters). This was determined with the use of advanced satellite technology in 1999. However, the same geological forces that created Mount Everest are still at work. The mountain will probably grow higher over the course of many years.

Mount Everest was named for Sir George Everest, a British surveyor-general of India in the 1800's. Tibetans call Mount Everest *Chomolungma.* Nepalese call the mountain *Sagarmatha.*

Many climbers have tried to scale Mount Everest since the British first saw it in the 1850's. Avalanches, crevasses, and strong winds have combined with extreme steepness and thin air to make the climb difficult. On May 29, 1953, Sir Edmund Hillary of New Zealand and Tenzing Norgay, a Nepalese Sherpa guide, became the first men to reach the top. They were part of a British expedition led by Sir John Hunt. It left Kathmandu, Nepal, on March 10, 1953, and approached the mountain from its south side—which had been called unclimbable. As the climbers advanced up the slopes, they set up a series of camps, each with fewer members. The last camp, one small tent at 27,900 feet (8,504 meters), was set up by Hillary and Tenzing Norgay, who reached the summit alone. See **Hillary, Sir Edmund P.; Tenzing Norgay.**

In 1956, a Swiss expedition climbed Mount Everest twice. The expedition also became the first group to scale Lhotse, the fourth highest peak in the world and one of the several summits that make up the Mount Everest *massif* (the main part of a mountain range).

In 1963, Norman G. Dyhrenfurth led a United States expedition that climbed Mount Everest. On May 1, James W. Whittaker, accompanied by Nepalese guide Nawang Gombu, became the first American to reach the top. He climbed to the summit from the south. Thomas F. Hornbein and William F. Unsoeld, members of the same expedition, became the first people to scale the difficult west ridge. They reached the top on May 22.

On May 16, 1975, Junko Tabei of Japan became the first woman to reach the top. Her party climbed the southeast ridge. Later that year, on September 24, Dougal Haston and Doug Scott became the first climbers to reach the top by climbing the mountain's southwest face. Haston and Scott were part of a British expedition. On May 10, 1980, two members of a Japanese expedition, Takashi Ozaki and Tsuneo Shigehiro, became the first people to reach the top from the north.

On May 5, 1988, two expeditions reached the top of Mount Everest from opposite sides for the first time. The climbing teams consisted of members from China, Japan, and Nepal. A team of three began in Nepal and climbed the mountain's south face. A team of eight began its climb of the north face in Tibet.

Some Sherpas claim a creature that they call the *Yeti,* or *Abominable Snowman,* lives around Everest. But climbers have not seen it. Sir Edmund P. Hillary

Mount Fuji, *FOO jee,* is the highest mountain in Japan (12,388 feet, or 3,776 meters). Mount Fuji lies on the island of Honshu, about 60 miles (97 kilometers) southwest of Tokyo. The Japanese call the mountain *Fuji-yama* or *Fuji-san.* Fuji has long, symmetrical slopes. Its top often is hidden by clouds. Its crown of snow melts in summer. The Japanese have long considered it a sacred mountain, and more than 50,000 pilgrims climb to its summit every year. The top contains an inactive volcano crater. See also **Japan** (picture); **Mountain** (diagram: Major mountains). Kenneth B. Pyle

Mount Godwin Austen. See **K2.**

Mount Hood is a majestic, snow-capped mountain in northern Oregon (see Oregon [physical map]). The state's highest peak, Mount Hood rises 11,239 feet (3,426 meters) above sea level in the Cascade Range. Skiers use it the year around. Lifts go up to the 10,000-foot (3,050-meter) level. Mount Hood also draws many mountain climbers.

Mount Hood is an inactive volcano. Its most recent period of eruptions took place from 1845 to 1865. The eruptions were minor. Through the years, glaciers and rivers have deeply eroded the slopes, adding to the mountain's striking appearance. In 1792, William Broughton, a British naval officer, became the first European to see Mount Hood. Broughton named the mountain for Samuel Hood, a British admiral.

Claude W. Curran

See also Oregon (pictures).

Mount Kanchenjunga, *KAHN chuhn JUNG guh,* also called Kinchinjunga, *KIHN chihn JUN gah,* is one of the highest mountains in the world. It rises 28,208 feet (8,598 meters). The mountain is part of the Himalaya and stands about 100 miles (160 kilometers) east of Mount Everest, between Nepal and the Indian state of Sikkim. A British expedition climbed Mount Kanchenjunga for the first time in 1955. See also Mountain (diagram: Major mountains). James A. Hafner

Mount Kenya, *KEHN yuh* or *KEEN yuh,* is the highest mountain in Kenya and the second highest mountain in Africa. Kilimanjaro in Tanzania is the only taller African mountain. Mount Kenya is an extinct volcano that rises 17,058 feet (5,199 meters) in central Kenya. Although the mountain stands just south of the equator, it is capped by snow and has glaciers on its upper slopes.

Mount Kenya receives heavy rainfall. Coffee, Kenya's most valuable export crop, is widely grown on the mountain's slopes. The farmers in the region around Mount Kenya also grow beans, corns, and other crops.

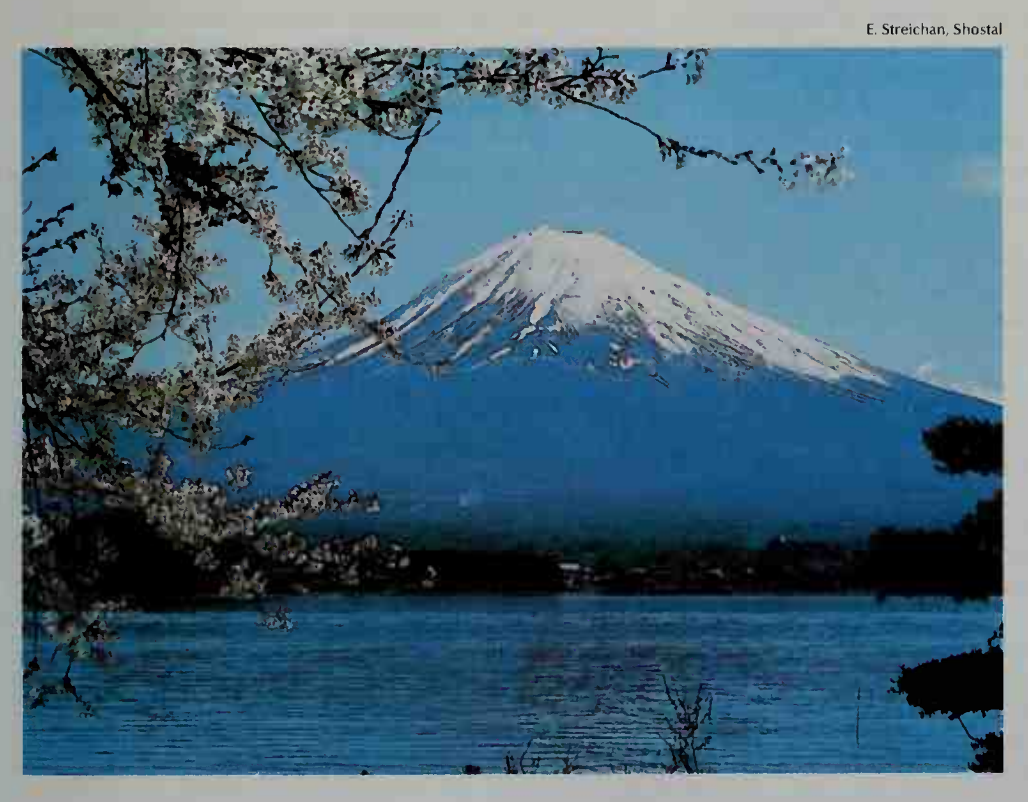
Mount Kenya forms part of Mount Kenya National Park. A large number of animals, including buffalo, monkeys, and a wide variety of birds, live in the park. The park also provides a starting point for people who come to climb the mountain. David J. Campbell

Mount Kilimanjaro. See Kilimanjaro.

Mount Kosciuszko, *KAHS ee UHS koh,* is the highest peak in Australia. It rises 7,310 feet (2,228 meters) above sea level in the Australian Alps in southeastern New South Wales. For location, see Australia (physical map).

Mount Kosciuszko stands in Kosciuszko National Park, one of Australia's most popular winter ski destinations. Summer tourist activities include hiking and trout fishing. During the summer months, a large variety of wildflowers covers the mountain slopes. Eucalyptus trees grow at the lower altitudes. Animals that live in the area include echidnas, kangaroos, and wallabies.

In 1840, the Polish-born explorer Paul Edmund de Strzelecki became the first white person to see the mountain. He named it after the Polish patriot Tadeusz Kościuszko. Edward L. Myles



See also Mountain (diagram: Major mountains).

Mount Logan is the highest peak in Canada and the second highest peak in North America. Only Mount McKinley in Alaska is higher (see Mount McKinley). Mount Logan rises 19,524 feet (5,951 meters) and is part of the Saint Elias Range in the southwest corner of the Yukon Territory. It lies in Canada's Kluane National Park among the world's largest concentration of ice fields and glaciers. The peak was named for Sir William E. Logan, director of the Geological Survey of Canada from 1842 to 1869. It was first climbed by a joint United States-Canadian team in 1925. G. Peter Kershaw

See also Mountain (diagram: Major mountains); Yukon Territory (map).

Mount Makalu, *MUH kuh LOO,* is one of the highest mountains in the world. Makalu stands in the Himalaya about 10 miles (16 kilometers) southeast of Mount Everest, on the border between Nepal and Tibet. The moun-

E. Streichan, Shostal

Mount Fuji, overlooking Lake Kawaguchi, rises 12,388 feet (3,776 meters) on the Japanese island of Honshu. It has been considered sacred since ancient times. Each summer, thousands of Japanese make a pilgrimage to the top.

tain's highest peak, Makalu I, rises 27,824 feet (8,481 meters). Makalu II is 25,130 feet (7,660 meters) high. In 1955, a group of French mountaineers led by Jean Franco became the first people to climb Makalu. James A. Hafner

See also **Mountain** (diagram: Major mountains).

Mount Mazama. See **Crater Lake**.

Mount McKinley, in south-central Alaska, is sometimes called the *top of the continent* because it has the highest peak in North America. The mountain actually has two peaks—the South Peak, which is 20,320 feet (6,194 meters) high; and the North Peak, which rises 19,470 feet (5,934 meters). For many years, the height of the South Peak was believed to be 20,269 feet (6,178 meters). But in 1956, after 10 years of surveys, the U.S. Geological Survey established the height as 20,320 feet (6,194 meters).

Mount McKinley is part of the Alaska Range. It was named for William McKinley, who served as president of the United States from 1897 to 1901. The Athabaskan Indians of Alaska called the mountain *Denali,* which means *The Great One* or *The High One.* Mount McKinley is the chief scenic attraction of Denali National Park. The north side of the mountain represents one of the world's greatest unbroken *precipices* (steep cliffs).

Between 1903 and 1913, at least 11 expeditions tried unsuccessfully to climb to the summit of Mount McKinley. In 1906, Frederick A. Cook claimed to have been the first person to reach the summit. But his claim was found to be false in 1910 (see **Cook, Frederick A.**).

Also in 1910, a group of miners and prospectors known as the Sourdough party climbed Mount McKinley. They said they had reached the top and claimed to have erected a flagpole at the summit. In 1913, Hudson Stuck, Harry P. Karstens, and two companions became the first people to successfully climb to the top of the South Peak. From there, they sighted the flagpole planted by the Sourdough party on the slightly lower North Peak. In 1932, Alfred D. Lindley, Harry J. Liek, Erling Strom, and Grant Pearson reached the top of the South Peak. Two days later, they climbed the North Peak, thus becoming the first people to ascend both peaks.

Claus-M. Naske

Mount McKinley National Park. See **Denali National Park**.

Mount of Olives is a hill about $\frac{1}{2}$ mile (0.8 kilometer) east of Jerusalem. It is also called Mount Olivet. According to the Bible, Jesus went down from Olivet to make His triumphal entry into Jerusalem. Each night of His last week, He returned to Olivet (Luke 21:37) until the night of His betrayal. Acts 1 names Olivet as the place from which He rose into Heaven. The Church of the Ascension stands on Mount Olivet where the Ascension is supposed to have occurred. One area of the Mount is called Gethsemane. According to Mark and Matthew, Jesus prayed there before His betrayal. See also **Gethsemane; Jerusalem** (map); **Jesus Christ** (The Passion [The trial]). Stanley K. Stowers

Mount Olympus, *oh LIHM puhs,* is the highest mountain in Greece. It rises 9,570 feet (2,917 meters) at the eastern edge of the ridge that divides Thessaly from Macedonia (see **Greece** [map]). The mountain's summit is usually covered with snow and hidden in clouds. In Greek mythology, the peak of Mount Olympus was the site of the magnificent palace of Zeus, king of the gods, who was also god of thunder, lightning, and rain.

The ancient Greeks believed 11 other gods and goddesses lived in Zeus's palace. They included his wife, Hera; his children Athena, Apollo, Artemis, Hermes, and Ares; and his brother Poseidon. These and the other deities who lived in the palace were called the *Olympian gods.* They formed for Zeus a divine family and court, much like the human family and court of such mortal kings as Agamemnon, legendary king of Mycenae. In the palace, the Olympians enjoyed fine banquets and music but had occasional family quarrels. The Muses, nine daughters of Zeus, were thought to live on the slopes of the mountain. Jon D. Mikalson

See also **Mountain** (diagram: Major mountains).

Mount Parnassus. See **Parnassus**.

Mount Pelée, *puh LAY,* is an active volcano on the north end of Martinique in the French West Indies. It rises 4,583 feet (1,397 meters) above sea level.

The volcano erupted violently in 1902, after lying dormant since 1851. Floods of mud loosened by the eruption devastated the slopes of the mountain. A heap of lava 1,000 feet (300 meters) high formed in the crater. A slender spire of rock was thrust up another 1,000 feet from the crater. An avalanche of red-hot lava and clouds of hot gas swept down the mountain, destroying the city of St.-Pierre and killing about 38,000 people. Only one person, a man in prison in the city's dungeon, escaped alive. Milder eruptions occurred between 1929 and 1932. The French government maintains a volcano observatory on Mount Pelée. Gustavo A. Antonini

Mount Pinatubo is a volcanic mountain on the island of Luzon in the Philippines. It lies about 55 miles (90 kilometers) northwest of Manila. For location, see **Philippines** (map). Mount Pinatubo rises 4,875 feet (1,486 meters) and is part of the Ring of Fire, a belt of volcanoes encircling the Pacific Ocean.

On April 2, 1991, villagers noticed the first signs of volcanic activity on Mount Pinatubo, which had not erupted for more than 600 years. Steam began exploding from the side of the mountain. On June 15, a powerful eruption tore away the top of the volcano and left a *caldera* (crater) about 1 $\frac{1}{4}$ miles (2 kilometers) wide. Lava flowed down the mountain, and rock fragments and ash shot 22 miles (35 kilometers) into the air. Monsoon rains that fell after the eruption caused avalanches of volcanic ash and debris. The avalanches damaged buildings, choked rivers, and killed hundreds of people. The eruption also released about 20 million tons (18 million metric tons) of sulfur dioxide into the atmosphere.

Katharine V. Cashman

See also **Philippines** (picture: Automobiles covered with volcanic ash).

Mount Pisgah, *PIHZ guh,* is a small mountain range located in central Jordan. According to the Bible (Deuteronomy 34:1), Moses saw the Promised Land from its highest peak, Mount Nebo. The peak towers 2,631 feet (802 meters) high. The Pisgah range rises east of the Jordan River. The northern half of the Dead Sea lies southwest of the range.

Mount Pisgah was part of the ancient kingdom of Moab in Palestine. According to the Bible, Balak, a king of Moab, built his seven altars for the prophet Balaam

on Mount Pisgah, offered sacrifices, and asked Balaam to curse the people of Israel (Numbers 22-24).

Peter Gubser

Mount Rainier, *ruh NIHR* or *RAY neer,* in Mount Rainier National Park, near Seattle, is the highest mountain in the state of Washington. The peak rises 14,410 feet (4,392 meters) above sea level. Gassy fumes still rise from Mount Rainier's great volcanic cone, but the mountain's deeply cut slopes show that the volcano was largely formed long ago. Roads lead through fine forests of cedar and fir to Rainier. Mountain torrents, patches of red heather, and white avalanche lilies line these scenic routes.

Explorer George Vancouver saw the mountain peak from his ship in 1792. He named it for his friend and fellow British naval officer Peter Rainier. Hazard Stevens and P. B. Van Trump became the first people to climb to the mountain's top. They climbed it by way of the Gibraltar Route in 1870. The climb to the top is a test of endurance. Even shorter climbs are challenging because of the mountain's deep crevasses, ice caves, and steep cliffs.

Paradise Valley perches at 5,400 feet (1,650 meters) on the slope near the timber line on Mount Rainier. Paradise Valley lies between the Nisqually and Paradise glaciers. Twenty-five glaciers feed the swift streams and tumbling waterfalls that roar through the glacial valleys. Wildflowers of many colors border the glaciers. The Nisqually and the Cowlitz glaciers are the most often explored of the ice regions in the park. The 90-mile (140-kilometer) Wonderland Trail encircles the mountain.

Jois C. Child

See also **Mountain** (diagram: Major mountains).

Mount Rainier National Park, *ruh NIHR* or *RAY neer,* is in west-central Washington, near Seattle. The park was established in 1899 to preserve the natural beauty of majestic, ice-clad Mount Rainier. For the area of Mount Rainier National Park, see **National Park System** (table: National parks).

An old 14,410-foot (4,392-meter) volcanic cone, Mount Rainier bears a glacier system over 35 square miles (90 square kilometers) in extent. Twenty-five "rivers of ice" originate at or near its summit.

Covering the lower slopes of the mountain are magnificent forests of Douglas-fir, western hemlock, and western redcedar. Blacktail deer and mountain goats are among the animals that visitors may see in Mount Rainier National Park.

To enjoy fully the park's spectacular scenery and interesting natural phenomena, visitors must hike or ride horseback. One park trail—the 90-mile (140-kilometer) Wonderland Trail—circles the peak and enters remote areas. In winter, Paradise Valley, on the south side of Mount Rainier, is popular for cross-country skiing.

Critically reviewed by the National Park Service

Mount Rushmore National Memorial is a huge carving on a granite cliff called Mount Rushmore in the Black Hills of South Dakota. Mount Rushmore National Memorial shows the faces of four American presidents: George Washington, Thomas Jefferson, Theodore Roosevelt, and Abraham Lincoln. The head of Washington is as high as a five-story building (about 60 feet, or 18 meters). The height of the head is to the scale of a human being 465 feet (142 meters) tall.

The American sculptor Gutzon Borglum designed the Mount Rushmore memorial and supervised most of its work. Workers used models that were one-twelfth actual size to obtain measurements for the figures. The workers cut the figures from Mount Rushmore's granite cliff by means of drills and dynamite. Work on the memorial began in 1927, and it continued, with lapses, for over 14 years. Borglum died in 1941, before the memorial was completed, and his son Lincoln finished the work.

Mount Rushmore stands in the mountains 25 miles (40 kilometers) from Rapid City. The memorial rises 5,725 feet (1,745 meters) above sea level, and more than 500 feet (150 meters) above the valley. Thus, Mount Rushmore stands taller than the Great Pyramid of Egypt (see

Shostal

Mount Rushmore is a memorial to four great Americans. It has the largest figures of any statue in the world. The head of George Washington, *left,* is as high as a five-story building. The other heads, *left to right,* are Thomas Jefferson, Theodore Roosevelt, and Abraham Lincoln.

Pyramids). The memorial is part of the National Park System.

Mount Saint Helens is a volcano in the Cascade Mountains, 95 miles (153 kilometers) south of Seattle. Mount St. Helens erupted violently on May 18, 1980. The eruption resulted in 57 deaths. It also caused hundreds of millions of dollars of damage to the surrounding area. Volcanic explosions blasted away more than 1,000 feet (300 meters) from the peak and created a huge crater. The volcano's elevation after the 1980 eruption was 8,364 feet (2,549 meters) above sea level. The eruption of Mount St. Helens was the first to occur in the continental United States outside Alaska since 1917, when Lassen Peak in northern California last erupted.

Mount St. Helens has erupted many times in the past 4,500 years, but it was inactive from 1857 until 1980. Hot ash and rocks from the 1980 eruption started forest fires and melted snow on the upper slopes of the mountain. The resulting floods and mud slides washed away buildings, roads, and bridges. Explosions flattened millions of trees. The eruption also spread a thick layer of volcanic ash over a wide area, destroying crops and wildlife and blanketing cities. Between May 1980 and 1986, many small eruptions occurred. But these did not result in deaths or significant property damage. Geologists expect Mount St. Helens to continue to erupt from time to time. Jois C. Child

See also **Mountain** (diagram: Major mountains); **Washington** (picture: The eruptions of Mount St. Helens).

Roger Werths, Woodfin Camp, Inc.

Mount St. Helens caused many deaths and enormous damage in southwestern Washington after erupting in 1980, shown here. The eruption was the first in the continental United States outside Alaska since 1917.

Mount Shasta towers 14,162 feet (4,317 meters) above sea level in northern California. It rises almost 10,000 feet (3,000 meters) above the low mountains on which it rests. Mount Shasta is the southernmost of the great volcanoes in the Cascade Range between northern California and the Canadian border. For location, see **California** (physical map). Successive lava flows over thousands of years made Mount Shasta. The mountain is not considered an active volcano, but it has a hot spring near its summit.

A newer and smaller volcanic cone, called *Shastina,* lies on the western slopes of Shasta, about 2,500 feet (762 meters) below the summit. It has an almost perfectly preserved summit crater. Five small valley glaciers are found high on the sides of the peak, above 10,000 feet (3,000 meters). Roger Barnett

Mount Sinai, *SY ny,* is the mountain on which Moses received the *Decalogue* (Ten Commandments) and learned much of the Hebraic law. Mount Sinai is also called *Horeb* in the Bible. Its name in Arabic is *Jabal Musa* (Mount of Moses). Mount Sinai is located in Egypt in the district of the Sinai Peninsula, a triangle between the two north arms of the Red Sea. For the past 1,500 years, scholars have considered Mount Sinai to be an 8,000-foot (2,400-meter) peak in the southern tip of the triangle. Today, many experts think it may be in the peninsula's northeastern part. Gary G. Porton

Mount Vernon was the home of George Washington. It lies in Fairfax County, Virginia, about 15 miles (24 kilometers) south of Washington, D.C. The tomb of George and Martha Washington is also located at Mount Vernon. More than a million tourists visit this national shrine each year. The present estate covers about 500 acres (202 hectares).

Washington lived at Mount Vernon as a farmer before he was called upon in 1775 to take command of the Continental Army in the Revolutionary War. When the war ended, he came back to Mount Vernon to retire. But his service to his country was not finished. In 1789, he was elected as the first President of the United States. At the end of his second term as President, Washington returned to the estate to live quietly until his death two years later.

The buildings. The mansion is a large, comfortable building with white pillars. It stands on a high bluff overlooking the Potomac River. There are 20 rooms in the $2\frac{1}{2}$-story building. The attic has dormer windows. The mansion is built of wood, but the board siding on the outside is arranged to make it look like stone. The house has great dignity and beauty.

George Washington's father, Augustine, built the main section of the house during the 1730's. The elder Washington called the country estate the Little Hunting Creek Plantation. George Washington's elder half brother, Lawrence, inherited the property in 1743. He renamed it Mount Vernon in honor of Admiral Edward Vernon, his former commander in the British Navy.

Mount Vernon Ladies' Association

Mount Vernon, the estate of George Washington, covers about 500 acres (202 hectares) in Fairfax County, Virginia. It includes a mansion, *center rear,* and about 15 smaller buildings.

B Glander, Shostal

The mansion is a $2\frac{1}{2}$-story building with 20 rooms. It is made of wood.

Mount Vernon Ladies' Association

Washington's bedroom is on the second floor of the south addition to the mansion. Washington died in this bed in 1799.

Robert Srenco, Shostal

The Mount Vernon kitchen, a two-room building, stood near the mansion. The kitchen's west room is shown above.

Mount Vernon Ladies' Association

The small dining room at Mount Vernon was the scene of many dinners during the late 1700's.

George Washington inherited Mount Vernon in 1761. He added the *piazza,* a two-story porch along the river side of the house, after returning from the Revolutionary War. See **Virginia** (picture).

The inside of the house has been restored as nearly as possible to its original state. Many of the original furnishings have been returned.

About 15 smaller buildings stand at the sides and behind the mansion. Some were living quarters for servants and craftworkers. Others housed farm tools and animals. Nearly everything Washington's family needed was grown or made on the plantation, which at that time totaled about 7,600 acres (3,075 hectares).

The grounds and the tomb. The grounds around the mansion add to the beauty of the estate. A wide, green lawn sweeps away from the east porch and ends in a park at the foot of the hill. Flower gardens and fruit and shade trees surround the buildings on the estate. Washington himself planted many of the trees that still flourish. The simple ivy-covered tomb where George and Martha Washington are buried stands at the foot of a hill, south of the house.

A national shrine. By 1853, the estate was in a rundown condition because it could not be maintained as a self-supporting farm. Then a group of women formed the Mount Vernon Ladies' Association to save the grounds and buildings of Mount Vernon. These women aroused public interest in the project. Gifts of money from people in all parts of the country enabled them to buy the estate. They restored buildings that had fallen into ruin and repaired the mansion. They recovered many of the original articles of furniture and decoration. John Augustine Washington, Jr., the last private owner of Mount Vernon, presented the estate with the key of the Bastille, which is exhibited in the central hall. The French statesman Marquis de Lafayette had given the key of the French fortress to Washington in 1790, during the French Revolution. Other valuable personal articles of the Washington family were also placed in the house. Thus, this historic place was saved to become a memorial. The Mount Vernon Ladies' Association now cares for the estate.

In 1931, the United States government completed the scenic Memorial Highway from Washington, D.C., to Mount Vernon. The road follows the banks of the Potomac River.

Mount Vernon, New York (pop. 68,381), is a historic suburb of New York City (see **New York** [political map]). The first permanent settlement in the Mount Vernon area, Eastchester, was established in 1664. In 1735, a New York newspaper publisher named John Peter Zenger was put on trial for criticizing the governor of the New York colony for interfering in an election held in Eastchester. Zenger's trial, in which he was found innocent of libel charges, helped establish the principle of freedom of the press in the United States.

In 1851, the Industrial Home Association of New York bought land for a community of homes there for workers who wanted to avoid the high rents and overcrowding of New York City. The association named the community Mount Vernon, after the home of George Washington, the first United States president. Mount Vernon was incorporated as a village in 1853 and chartered as a city in 1892. Old St. Paul's Episcopal Church, used by the British as a hospital during the Revolutionary War in America (1775-1783), still stands in Mount Vernon. It was named a national historic landmark in 1943. Mount Vernon has a mayor-council form of government. John Kenneth White

Mount Vesuvius. See **Vesuvius.**

Mount Washington is the highest peak in New Hampshire and in the Northeastern United States. It rises 6,288 feet (1,917 meters) in the Presidential Range of the White Mountains. It lies in a resort area. In the summer, the summit can be reached by hiking trails, automobile road, or cog railway. See also **New Hampshire** (picture); **White Mountains.** Robert L. A. Adams

Mount Whitney, one of the highest mountains in the United States, rises 14,495 feet (4,418 meters). Snow-capped Mount Whitney lies in the southern part of the Sierra Nevada Range of California. Its granite pinnacles and domes rise sharply to more than 10,000 feet (3,000 meters) above the Owens Valley to the east. Mount Whitney was named for Josiah Dwight Whitney (1819-1896), who served as state geologist of California.

Roger Barnett

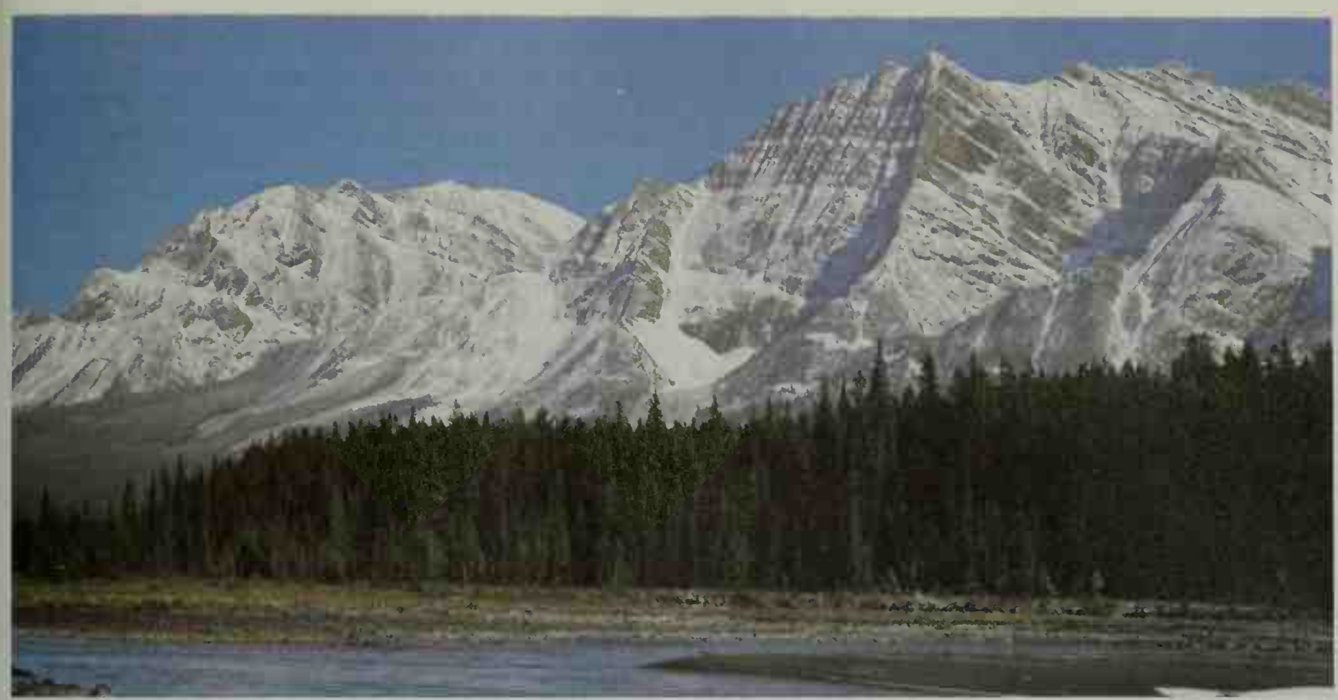
Mount Wilson Observatory is an astronomical observatory in southwestern California. It stands on Mount Wilson, 5,710 feet (1,740 meters) above sea level, about 10 miles (16 kilometers) northeast of Pasadena.



George Ellery Hale, an American astronomer, founded the observatory in 1904. It originally specialized in the study of the sun and is still a leading center for research on the magnetic fields and the velocities of the solar surface. The observatory has two solar telescopes, which are mounted in towers 150 and 60 feet (46 and 18 meters) high.

The observatory also operates two reflecting telescopes, one with a diameter of 60 inches (1.5 meters) and the other with a diameter of 100 inches (2.5 meters). These instruments are used to study stars. American astronomer Edwin P. Hubble used the 100-inch reflecting telescope to discover the expansion of the universe (see **Universe** [Size of the universe]). In 1995, the 100-inch telescope became the first large telescope in the United States to be fitted with an *adaptive optical system* to reduce atmospheric blurring.

Until 1980, the Mount Wilson Observatory was operated jointly by the Carnegie Institution of Washington, D.C., and the California Institute of Technology at Pasadena. In 1980, the Carnegie Institution assumed sole administrative control of the Mount Wilson Observatory. The Carnegie Institution continued to operate the observatory until 1989. That year, administrative control of the observatory was transferred to the Mount Wilson Institute, a private organization.

Majestic mountain peaks tower above their surroundings. These mountains, part of the rugged Rocky Mountain system, rise along the Athabaska River in Alberta, Canada.

Mountain

Mountain is a landform that stands much higher than its surroundings. Mountains generally are larger than hills, but what people call *hills* in one place may be higher than what people call *mountains* elsewhere. For example, the Black Hills of South Dakota and Wyoming stand higher above their surroundings than do the Ouachita Mountains of Arkansas and Oklahoma.

Mountains generally have steep slopes and sharp or slightly rounded peaks or ridges. Many geologists consider an elevated area a mountain only if it includes two or more zones of climate and plant life at different altitudes. In general, the climate becomes cooler and wetter with increasing elevation. In most parts of the world, a mountain must rise about 2,000 feet (600 meters) above its surroundings to include two climate zones.

A mountain may be a single peak, such as a lone volcano, or it may be part of a mountain range. A group of mountain ranges forms a mountain system. The Pacific Mountain System, for example, is made up of the Cascade Range and several other mountain ranges along the west coast of North America.

Mountains occur in the ocean as well as on land. Many islands are mountains on the ocean floor whose peaks rise above the surface of the water. The world's longest mountain system—the Mid-Atlantic Ridge—is almost totally underwater. It stretches more than 10,000 miles (16,000 kilometers) from the North Atlantic Ocean nearly to Antarctica. Some of the ridge's highest peaks form such islands as Iceland and the Azores.

The height of a mountain is usually expressed as the distance that its peak rises above sea level. The world's highest mountain, Mount Everest, rises 29,035 feet (8,850 meters) above sea level, according to a 1999 measurement. Climbers made the measurement using modern satellite technology. Their equipment collected data from satellites of the Global Positioning System, then transmitted the data to stations below for analysis. The measured altitude is 7 feet (2 meters) higher than the altitude that had been officially recognized since 1954.

Mauna Kea, a volcano on the island of Hawaii, has the world's largest rise from base to peak. From the volcano's base on the floor of the Pacific Ocean to its peak 13,796 feet (4,204 meters) above the ocean surface, Mauna Kea rises a total of 33,476 feet (10,203 meters)—more than 6 miles.

Donald F. Eschman, the contributor of this article, is Professor Emeritus of Geology at the University of Michigan.

The importance of mountains

Mountain ranges are important because they determine the climate and water flow of surrounding regions. Mountains are also important for the plants and animals they support, and as a source of minerals. Mountain ranges influence human activities, shaping patterns of transportation, communication, and settlement.

Climate. Mountain ranges strongly affect air movements and precipitation patterns. The temperature of the air drops as altitude increases. Cold air cannot hold as much moisture as warm air can. As a result, when warm, moist air moves up the windward slope of a mountain, it cools and the water vapor it holds condenses into water droplets. The water then falls on the windward slope as rain or snow.

By the time air passes the crest of a mountain, it has lost most of its moisture. For this reason, the side of the mountain away from the wind, called the *leeward side,* is drier than the windward side. The dry area on the leeward side of a mountain range is called a *rain shadow.* Many of the world's deserts lie in rain shadows.

Water flow. Mountains affect the availability of water for vast areas. Because so much precipitation falls on mountain slopes, many rivers have their headwaters in mountain regions. The Rio Grande and the Colorado River, for example, receive nearly all their water from mountains. Much of the snow in high mountains melts only during the summer. Thus, mountains act as reservoirs, feeding streams and rivers even during periods of summer drought.

Because of their steep slopes and abundant water flow, mountainous areas make good locations for hydroelectric plants, which convert the energy of falling water into electric power. Mountainous Norway produces nearly all its electricity from water power.

Plants and animals. Because mountains include diverse conditions at different elevations, they provide environments suitable to many kinds of plant and animal life. Few living things survive in the bitter cold of snow-capped mountain peaks. Just below the snowfields, however, a variety of small animals such as chinchillas and pikas make their home. A few sure-footed large animals such as mountain goats and sheep also live there. These animals feed on shrubs, mosses, and other plants that grow above the *timber line,* the line beyond which trees will not grow because of the cold.

Below the timber line, many mountains have large forests filled with a wide range of plant and animal life. Many areas of the western United States are too dry to support trees except in the cooler, wetter climate of the mountains. The lumber industry in such regions depends on timber grown in mountainous areas. Many animals that are important to the fur industry or for big game hunting also live in the mountains.

Minerals. Much of the world's mineral resources come from mountainous regions. Mountains are formed by such geologic processes as volcanic eruptions and earthquakes. These processes may bring valuable minerals near the surface, where they can be mined.

Human activities. In many parts of the world, mountains have long served as barriers, hindering transportation, settlement, and communication. The isolation of mountain communities has created much diversity of cultures. In Switzerland's Alps, for example, the people speak hundreds of dialects of four different languages.

Mountains are also important recreation areas. Each year, millions of people vacation in mountainous areas to camp, hike, ski, climb, or just to enjoy the fresh air and spectacular views.

How mountains are formed

Mountains are created over long periods of time by tremendous forces in the earth. Since the early 1960's, earth scientists have developed a theory called *plate tectonics* that explains the formation of mountains and other geologic features. According to this theory, the earth's outer shell is made up of about 30 rigid plates of various sizes. The continents and the ocean basins make up the outermost part of these plates. The plates are in slow, continuous motion. Most mountain building occurs along boundaries between plates.

There are five basic kinds of mountains, depending on the process by which they were formed: (1) *volcanic mountains,* (2) *fold mountains,* (3) *fault-block mountains,* (4) *dome mountains,* and (5) *erosion mountains.*

Major mountain ranges may include more than one of these kinds. The Front Range of the Rocky Mountains in Colorado, for example, began as fold mountains. Later, geologic forces pushed up large blocks of earth's crust in the range, creating fault-block mountains.

Volcanic mountains, such as Washington's Mount Rainier and Japan's Mount Fuji, form when molten rock from deep within the earth erupts and piles up on the surface. As a result, volcanic mountains consist chiefly of *igneous rocks,* such as basalt and rhyolite, which are formed when molten material cools and solidifies. Igneous rocks are one of the three major types of rocks. The other types, *sedimentary rocks* and *metamorphic rocks,* can be found in mountains formed by other processes.

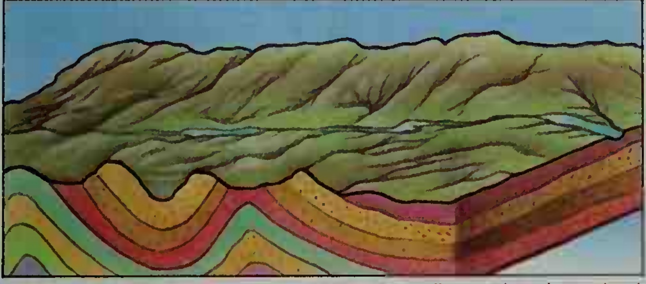
Much volcanic mountain building takes place in areas called *subduction zones.* In these zones, two of the huge plates making up the earth's crust collide, and the edge of one plate is thrust under the edge of the other in a process called *subduction.* Friction and the earth's heat cause the material in the sinking plate to melt and rise to the surface, creating volcanic eruptions. Such volcanic activity resulting from subduction formed the Cascade Range in North America, the Andes Mountains of South America, and the Himalaya in Asia.

If the subduction zone lies under an ocean, the volcanic activity there may form a chain of islands called an *island arc.* The Aleutian Islands of Alaska and the Mariana Islands in the Pacific Ocean are such island arcs.

Volcanic mountain building in the ocean is also associated with the separation of plates. Molten rock from the earth's interior wells up between two plates, creating a submerged mountain range called a *mid-ocean ridge.* The Mid-Atlantic Ridge formed in this way. As the molten rock cools and the plates continue to move apart, the solidified material becomes new ocean floor.

The formation of still other volcanic mountains is independent of the action of the plates. Earth scientists believe that these mountains originate from *mantle plumes* —columns of molten rock that rise from deep inside the earth. These plumes are stationary in relation to the plates moving above them. When the molten rock nears the surface, it forms a pocket of intense heat, or *hot spot,* that erupts as a volcano. Over a long period of time, as the plate above the plume moves, the plume creates a line of volcanoes. The Hawaiian Islands formed in this manner as the Pacific Plate moved in a northwesterly direction over a stationary plume.

Fold mountains, such as the Appalachian Mountains in the eastern United States and the Alps in Europe, form when two plates meet head-on and their edges crumple. Fold mountains consist mainly of sedimentary rocks, such as limestone and shale, which form when *sediments* (particles of older rock and plant and animal remains) settle to the bottom of bodies of water and harden. Heat and pressure change some of the rocks into metamorphic rocks, such as marble and slate.



The thickest deposits of sedimentary rock generally accumulate along the edges of continents. When plates and the continents riding on them collide, the accumulated layers of rock crumple and fold like a tablecloth that is pushed across a table. This creates fold mountains in which the wrinkling of the rock layers may range from gentle, wavelike patterns to sharp, complex folds with extensive *faulting* (fracturing) of the layers. Much of

the Appalachian Mountains consists of gently folded rock. Europe's Alps, however, are so sharply folded that a person climbing in some areas may cross the same layer of rock several times during a single ascent. The first time the layer is right side up, the next time upside down, then right side up again, and so on. In such intensely folded and faulted mountains, molten rock may push up from the earth's interior into the sedimentary layers, creating veins of granite and other igneous rocks. Heat and pressure caused by the weight of the upper rock layers may change sedimentary rock in the deeper layers into metamorphic rock, such as schist.

Fault-block mountains consist of huge blocks of the earth's crust that have been tilted or pushed up along a fracture line called a *fault.* The Teton Range in Wyoming, the Wasatch Range in Utah, the Sierra Nevada in California, and the Harz Mountains in Germany are fault-block mountains. Some blocks are pushed up between two separate faults. More commonly, a block is tilted up along one side of a single fault.

In fault-block mountains, the steep slope of the uplifted blocks results in rapid erosion of the exposed rock. The debris created by this erosion accumulates at the base of the mountain. Many of the isolated mountains of western Arizona, western Utah, and Nevada are fault-block mountains separated by broad plains filled with such debris.

Dome mountains, such as the Black Hills of South Dakota and the Adirondack Mountains of New York, form where geologic forces lift the earth's crust into a broad bulge or dome. Because the dome is raised above its surroundings, it is vulnerable to increased erosion. Layers of sedimentary rock covering the dome erode, exposing underlying igneous and metamorphic rock. This harder underlying rock then erodes irregularly. As a result, peaks and valleys are formed.

WORLD BOOK illustration by Paul D. Turnbaugh

Fold mountains form when sections of the earth's crust collide. Such collisions cause layers of rock in the crust to crumple and fold, often creating the wavelike patterns shown above.

WORLD BOOK illustration by Paul D. Turnbaugh

Fault-block mountains form when huge blocks of the earth's crust are pushed up along a fracture line called a *fault.* Such blocks may also be pushed up between several faults, *above.*

Erosion mountains. A few mountains, such as the Catskill Mountains in New York, result from the erosion of a thick pile of sedimentary rock. This type of mountain is all that remains of a plateau after rivers or glaciers erode the plateau to form peaks and valleys.

Major mountain systems

The Appalachian Mountains extend from Alabama to the Gaspe Peninsula in Canada—a distance of about 1,500 miles (2,400 kilometers). They are composed mainly of folded and faulted sedimentary and metamorphic rock layers. Many scientists think that the Appalachian Mountains and the entire Appalachian region, which extends to the island of Newfoundland, were formed by three collisions of the North American Plate with other plates, beginning about 435 million years ago. The last collision was between the North American and African plates about 250 million years ago.

The Rocky Mountains stretch for about 3,300 miles (5,300 kilometers) from New Mexico into Alaska. The Rockies include fold, fault-block, and volcanic mountains. They began to form about 100 million years ago and were lifted again during the past 25 million years.

The Pacific Mountain System consists of two parallel chains of mountains that run for about 2,500 miles (4,000 kilometers) from southern California to Alaska. One chain, the Coast Ranges, includes the Olympic Mountains of Washington, many islands off the coast of British Columbia, and part of Alaska's coast and coastal islands. The Coast Ranges consist mostly of marine sediments but contain much volcanic rock in some areas. The other chain in the Pacific System consists of the Sierra Nevada of California, the Cascade Range of Oregon and Washington, the Coast Mountains of British Columbia, and the Alaska and Aleutian ranges. Both chains began forming about 240 million years ago, and have been further uplifted within the past 63 million years.

The Andes Mountains stretch along the west coast of South America for about 4,500 miles (7,200 kilometers). They are composed largely of igneous rocks, most of which were formed by volcanic eruptions within the past 65 million years. The volcanic activity has resulted from the subduction of the Nazca Plate, which underlies the Pacific Ocean west of South America and is pushing beneath the South American Plate. The Andes and the Pacific Mountain System are part of the *Ring of Fire,* a belt of subduction zones that encircles the Pacific and includes most of the world's volcanoes. The southernmost section of the Ring of Fire consists of the mountains of Antarctica, including an extension of the Andes called the Antarctic Peninsula.

The Tethyan Mountain System (pronounced *TEE thee uhn*) extends across Africa, Europe, and Asia for well over 7,000 miles (11,000 kilometers). It includes the Atlas Mountains of northwestern Africa, the Alps and the Carpathian Mountains in Europe, and the Caucasus Mountains between Europe and Asia. In Asia, it continues through the Zagros Mountains, the Pamirs, the Karakoram Range, and the Himalaya.

The mountains of the Tethyan System consist largely of highly deformed sedimentary and igneous rocks that have been folded and faulted within the past 80 million years. Earth scientists consider the system to be a result

Mountains of the world

Some famous mountains

Name	Height above sea level In feet	In meters	Location	Interesting facts
Aconcagua	22,831	6,959	Andes in Argentina	Highest peak in the Western Hemisphere
Annapurna I	26,504	8,078	Himalaya in Nepal	Highest mountain climbed until 1953
Chimborazo	20,561	6,267	Andes in Ecuador	For many years thought to be the highest mountain in the Western Hemisphere
Cotopaxi	19,347	5,897	Andes in Ecuador	One of the world's highest active volcanoes
Ixtacihuatl	17,343	5,286	Plateau of Mexico	Aztec name for *white woman*
Jungfrau	13,642	4,158	Alps in Switzerland	Electric railroad partway up the mountain
K2, or Mount Godwin Austen, or Dapsang	28,250	8,611	Karakoram, or Mustagh, in Kashmir	Second highest mountain in the world
Kilimanjaro	19,331	5,892	Isolated peak in Tanzania	Highest mountain in Africa
Lassen Peak	10,457	3,187	Cascade in California	One of the few active U.S. volcanoes
Matterhorn	14,692	4,478	Alps on Switzerland-Italy border	Favorite for daring mountain climbers
Mauna Kea	13,796	4,205	Island of Hawaii	World's greatest rise from base to peak
Mauna Loa	13,677	4,169	Island of Hawaii	World's largest volcano
Mont Blanc	15,771	4,807	Alps on France-Italy-Switzerland border	Highest mountain in the Alps
Mount Ararat	16,849	5,137	Eastern Plateau in Turkey	Noah's Ark supposed to have rested on Ararat
Mount Cook	12,316	3,754	Southern Alps in New Zealand	Highest peak in New Zealand
Mount Elbrus	18,510	5,642	Caucasus in Russia	Highest mountain in Europe
Mount Etna	10,902	3,323	Island of Sicily	Volcano known to have erupted over 260 times
Mount Everest	29,035	8,850	Himalaya on Nepal-Tibet border	Highest mountain in the world; first scaled in 1953
Mount Fuji	12,388	3,776	Island of Honshu in Japan	Considered sacred by many Japanese
Mount Hood	11,239	3,426	Cascade in Oregon	Inactive volcano with many glaciers
Mount Kanchenjunga, or Kinchinjunga	28,208	8,598	Himalaya on Nepal-India border	Third highest mountain in the world
Mount Kenya	17,058	5,199	Central Kenya	Base straddles the equator
Mount Kosciuszko	7,310	2,228	Australian Alps	Highest peak in Australia
Mount Logan	19,524	5,951	St. Elias in Canada	Highest peak in Canada
Mount Makalu	27,824	8,481	Himalaya on Nepal-Tibet border	Fourth highest mountain in the world
Mount McKinley	20,320	6,194	Alaska Range in Alaska	Highest peak in North America
Mount Olympus	9,570	2,917	Greece	Considered home of the gods by early Greeks
Mount Rainier	14,410	4,392	Cascade in Washington	Highest peak in Washington
Mount St. Helens	8,364	2,549	Cascade in Washington	One of the few active U.S. volcanoes
Mount Shasta	14,162	4,317	Cascade in California	Famous for its twin peaks
Mount Whitney	14,495	4,418	Sierra Nevada in California	Highest mountain in California
Pico de Orizaba	18,410	5,610	Plateau of Mexico	Highest peak in Mexico
Pikes Peak	14,110	4,301	Front Range in Colorado	Most famous of the Rocky Mountains
Popocatépetl	17,887	5,452	Plateau of Mexico	Aztec name for *smoking mountain*
Vesuvius	4,190	1,277	Italy	Only active volcano on the mainland of Europe

Each mountain listed has a separate article in *World Book*.

of the African, Arabian, and Indian plates colliding into the Eurasian Plate. Earthquakes occur frequently along the Tethyan System, indicating that mountain building is still taking place.

Studying mountains

Why geologists study mountains. Geologists study mountains because such study provides important and useful knowledge. Analysis of the structure, composition, and distribution of mountains yields information about the geologic forces that shape the earth and about the makeup of the earth's interior. Geologists also study mountains to learn about the history of the earth, including the formation of earth's major features.

The study of mountains has led to the discovery of rich mineral deposits and is necessary in the ongoing search for useful mineral resources. Knowledge of mountain geology helps engineers design and build mountain roads, railroad beds and tunnels, and dams.

Measuring mountains. Accurately determining the location and height of mountains is particularly important for geographers and mapmakers. They often use aerial photography, in which an airborne camera takes a series of overlapping photographs of an area. Mapmakers then use a process called *photogrammetry* to create maps from the photographs.

Artificial satellites and high-flying aircraft provide accurate data about location and altitude by means of instruments called *radar altimeters.* A radar altimeter sends radio signals down to the earth and receives the signals after they have been reflected from the ground. It computes the distance to the ground based on the speed of the radio waves and the time they took to travel to the ground and back. Satellites of the Global Positioning System send radio signals to special receivers on a mountain. Computers use information contained in the signals to determine the altitude of the mountain. Mountain surveyors also use a technique called *laser ranging,* in which a laser beam is bounced off an object to determine its distance. Donald F. Eschman

Mountain ash is the name for a group of trees and shrubs that grow in the Northern Hemisphere. They grow chiefly in high places. The *American mountain ash* grows from the Canadian province of Newfoundland and Labrador south to northern Georgia. A mountain ash has compound leaves made up of several leaflets. The white flowers grow in large, flattened clusters. The orange-to-red fruits are clusters of berrylike *pomes.*

Mountain ash is valuable as wildlife food and as an ornamental tree for lawns and gardens. The wood from the *European mountain ash,* or *rowan tree,* may be used for making tool handles. Superstitious people once believed the rowan tree would drive away evil spirits.

Norman L. Christensen, Jr.

Scientific classification. The mountain ash belongs to the rose family, Rosaceae. The American mountain ash is *Sorbus americana.* The rowan tree is *S. aucuparia.*

See also **Tree** (Familiar broadleaf and needleleaf trees [picture]).

Mountain avens is a small, hardy plant that grows wild in northern and Arctic regions. It is the floral emblem of Canada's Northwest Territories. The plant has small, saucer-shaped, yellow or white flowers. It grows on high ledges, rocky slopes, and in tundra or *heath* (open wasteland) in North America, Europe, and Asia.

Walter S. Judd

Scientific classification. The mountain avens belongs to the rose family, Rosaceae. It is genus *Dryas.* The scientific name for the yellow mountain avens of the Canadian Rockies is *D. drummondii.* The common mountain avens is *D. octopetala.*

Mountain beaver, also called *sewellel,* is a rodent that lives along the Pacific coast and in nearby mountains. Mountain beavers, which are not related to true beavers, have lived on earth longer than any other rodent. They lived in North America at least 60 million years ago. They are also called *boomers* and *whistlers,* though they do not make booming or whistling noises. *Sewellel* is a Chinook Indian word meaning *robe.*

Mountain beavers are about 1 foot (30 centimeters) long and look like large voles rather than like beavers (see **Vole**). They have a short, thick body, short legs, a short tail, and small eyes and ears. Their fur is thick and short. Mountain beavers live in groups called *colonies.* They live in tunnels they dig in the banks of streams.

Clark E. Adams

Scientific classification. The mountain beaver is the only surviving member of the mountain beaver family, Aplodontidae. Its scientific name is *Aplodontia rufa.*

Mountain climbing is the sport of climbing mountain slopes to reach their peaks. It is also called *mountaineering* or *Alpinism.*

Mountain climbing as a sport started in Europe when people began to ascend peaks simply for the challenge and adventure. Most of the major mountains, except those in the most remote parts of the world, have been climbed. The tallest peak in North America, located on Mount McKinley, was first climbed in 1913. In 1953, Sir Edmund Hillary of New Zealand and Tenzing Norgay of Nepal became the first to reach the summit of Mount Everest in Asia, the world's highest mountain. See **Mount McKinley; Mount Everest.**

Mountaineers still try to be the first to conquer a tall peak. But the main focus of the sport has become the exploration of new routes up the most challenging mountains. Mountaineers are also attracted to established routes that are very difficult or particularly enjoyable.

Styles of mountain climbing. Mountaineers today place great importance on the style of ascent. Experienced mountaineers typically climb in teams of two or more, but they sometimes climb alone for the increased challenge and solitude.

The traditional method of climbing a peak is called the *expedition style.* In this style, large teams of mountaineers set ropes on difficult terrain and establish a network of well-stocked camps.

Mountaineers consider *Alpine style climbing* the purest and most challenging way to climb a peak. Mountaineers begin at the base of a peak and climb to its summit without returning for supplies or equipment. The Alpine style requires a rapid ascent because the climbers are limited to the provisions in their packs. Retreat from a route without the camps and ropes of expedition style is often more difficult and dangerous.

Challenge of the Himalaya. Many mountain ranges offer outstanding climbing challenges. But the immense peaks of the Himalaya, the world's highest mountains, are regarded as the greatest test in mountaineering. Himalayan climbing is particularly difficult and hazardous because of the high altitudes, extreme cold, and severe weather. The sport's new frontier has become the attempt to reach the summit of these peaks without bottled oxygen, large numbers of support climbers, and expedition style tactics.

Basic mountaineering equipment and methods. Mountaineers use climbing ropes, tied around the waist or into a waist harness, to protect them if they fall. On snow and ice slopes, mountain climbers ascend with the aid of ice axes and a set of metal spikes called *crampons* attached to the bottom of climbing boots.

In difficult terrain, climbers use a technique called *belaying* to stop a fall. In belaying, a lead climber ascends while a second climber releases the rope from a secure position. While advancing, the lead climber inserts pieces of gear into the snow, ice, or cracks in the rock, securing the rope to them with a *snap link* or *karabiner.* The lead climber then belays the second climber, who removes the pieces of gear to use them again.

Climbers descend from the summit by the easiest or quickest route. Often they *rappel* steep sections. Rappelling is a way of sliding down the climbing rope.

Mountain climbing safety. Mountaineering is hazardous. Mountain storms can bring high winds and very cold temperatures that make climbing extremely difficult. Mountaineers also face such dangers as avalanches, ice and rock falls, and hidden cracks in the ice and snow. At high elevations, such altitude sicknesses as pulmonary and cerebral edema can be life threatening.

Mountaineers can overcome these dangers by taking adequate precautions. They should observe the weather and note any changes in barometric pressure. On high peaks, mountaineers must allow themselves time to adjust to the reduced amount of oxygen. Climbing with helmets helps protect against falling ice and rock.

Different routes on a mountain require different levels of climbing skill. Mountaineers should select a climb that is within their ability. They must also know when to retreat if the weather changes or the climb becomes too difficult or dangerous.

Mountain climbing schools and clubs. There are many mountain climbing guide services in the United States. Two schools that provide instruction in mountain climbing are the National Outdoor Leadership School in Lander, Wyoming, and Outward Bound, Inc., in Garrison, New York. Information about mountain climbing clubs can be obtained by writing to the American Alpine Club in Golden, Colorado. Mark B. Hesse

Mountain goat is a white, woolly animal that lives on steep cliffs high in the mountains of western North America. The animal roams across mountains in Alaska, western Canada, and Montana, Idaho, and Washington. The mountain goat is a type of *goat antelope.* It looks more like a goat than an antelope but is only distantly related to true goats and sheep.

Most mountain goats stand from 3 to 4 feet (90 to 120 centimeters) tall at the shoulder. The males are larger than the females. Thick underfur and a long, hairy, white overcoat protect the mountain goat against severe winds and bitter cold in the winter months. Both females and males have short, powerful legs with large black hoofs and are sure-footed climbers. The *billy* (male) has slender horns that may measure as much as 1 foot (30 centimeters) long. The horns of the *nanny* (female) may be slightly longer. The female uses its horns to defend a *territory* (area) against other mountain goats. Adult females dominate males and can force even large males to leave an area.

The billy usually lives alone except during the mating season in November. The nanny's *gestation* (pregnancy) period lasts about six months, and she gives birth to a single kid or twins during the spring. Nannies and their kids live in groups during the summer and by themselves in their territory during winter. Mountain goats eat grasses, sedges, lichens, and the leaves and twigs of shrubs. Valerius Geist

David C. Fritts, Animals Animals

The mountain goat has short, sharp horns and a beard. Strong legs enable it to move about easily on rocky cliffs. A woolly coat provides protection against cold mountain winds.

Scientific classification. The mountain goat belongs to the bovid family, Bovidae. It is *Oreamnos americanus.*

Mountain laurel is an evergreen plant that grows naturally in eastern North America. As a shrub, it stands 5 to 10 feet (1.5 to 3 meters) tall. As a tree, it reaches 30 feet (9 meters) high or more. The mountain laurel has pink or white flowers, which may have purple markings. Its glossy, dark leaves are oblong and pointed at the ends. Its leaves and nectar are poisonous. The plant is also called *kalmia.* Mountain laurels are often used in landscaping, and the plant has been introduced into western North America and the United Kingdom.

James L. Luteyn

Scientific classification. Mountain laurel is in the heath family, Ericaceae. Its scientific name is *Kalmia latifolia.*

Mountain lion is a large wild animal of the cat family. Mountain lions once lived throughout the forests of the United States and southern Canada. When settlers moved in, they drove this animal out. The number of mountain lions has been greatly reduced in both these countries, except in large national and state or provincial parks. Today, mountain lions live chiefly in western provinces and states from British Columbia and Alberta to California and New Mexico. Small numbers dwell in southeastern Canada and New England and southward through the Appalachian Mountains. They are also found in uninhabited areas of Florida and certain other parts of the South. Mountain lions are more common outside the United States and Canada. They live throughout much of Mexico, Central America, and southward to the tip of South America.

The animal was called *mountain lion* by some American settlers, who thought it was a female lion. Other names for this animal are *cougar, catamount,* and *puma.* Especially in the eastern states, it is known as *panther,* a name that is also given to several other kinds of cat (see **Panther**).

An adult mountain lion may be either a gray color or a reddish or yellowish color called *tawny.* Its hairs are fawn-gray tipped with reddish-brown or grayish. This animal has no spots, and in this way it is different from the jaguar. The throat, the insides of the legs, and the belly are white, and the tip of the tail is black. Some mountain lions are solid black. A full-grown animal may be 5 feet (1.5 meters) long or more, not counting the tail, which is 2 to 3 feet (61 to 91 centimeters) long. The heaviest mountain lion on record weighed 227 pounds (103 kilograms). The body is slender, and the legs are long. The head is round and rather small.

Mountain lions have from one to five cubs at a time, generally two years apart. The average number is three. The cubs weigh about 1 pound (0.5 kilogram) at birth. They are covered with fur and are blind. They are lighter brown than their parents. The cubs have large brownish-black spots on the body and dark rings on the short tail. Adults care for their young until they are able to survive alone. Young lions need about two years to develop

Maurice Hornocker

A mountain lion may reach a length of 5 feet (1.5 meters) or more, not counting its tail. Among the cats of North and South America, only the jaguar is larger. Mountain lions hunt and kill deer, elk, and smaller prey, such as rabbits.

Warren Garst, Van Cleve Photography

Mountain lion cubs are covered with dark spots that disappear as the animals grow older. Cubs stay with their mother for up to two years.

enough skill in hunting to find their own food. They may live to be 10 to 20 years old.

The cry of the mountain lion can be terrifying. It sounds like a person screaming in pain. The animal also has a soft whistle call.

A mountain lion usually hunts at night, sometimes traveling long distances in pursuit of game. Its chief prey are deer and elk. Occasionally, a mountain lion will kill a bighorn sheep. In need it will feed on small mammals—even skunks and porcupines. A mountain lion keeps under cover while stalking its prey. It then leaps out upon the animal, breaking the animal's neck or dragging it down to the ground.

Ranchers regard mountain lions as pests. But the big cats seldom kill calves or other domestic animals. Biologists believe that mountain lions should be controlled but not killed off, because they play an important part in the animal world. Like most other large predators, they feed mainly on weak, sick, or old prey. Such animals can be burdens to their herds. By killing them, mountain lions help strengthen the herds. Mountain lions are very unlikely to attack people. Thomas L. Poulson

Scientific classification. The mountain lion is a mammal that belongs to the cat family, Felidae. Its scientific name is *Felis concolor.*

Mountain men. See Fur trade (The 1800's); Westward movement in America (Exploration).

Mountain nestor. See Kea.

Mountain pass is a passageway over a mountain barrier. Passes generally occur at low points on mountain watersheds, or in valleys between mountain ridges. The importance of a mountain pass depends on the need for communication between the people who are living on each side.

Well-known passes include Donner (7,088 feet, or 2,160 meters) in California; Brenner (4,508 feet, or 1,374 meters) between Italy and Austria; and Khyber (3,518 feet, or 1,072 meters) between Pakistan and Afghanistan.

Mountaineering. See Mountain climbing.

Mountbatten, Louis (1900-1979), a member of the royal family of the United Kingdom, distinguished himself as a military leader and as the last *viceroy* (ruler) of the British colony of India. He served as chief of combined British operations during World War II (1939-1945). Mountbatten later became first sea lord, the United Kingdom's highest naval officer. As viceroy of India, he helped arrange for that country's independence.

Mountbatten was born on July 25, 1900, in Windsor, England. His given and family name was Louis Francis Albert Victor Nicholas Battenberg. He was the son of Prince Louis of Battenberg. Mountbatten joined the Royal Navy in 1913. He studied at the Royal Naval College.

When World War II began in 1939, Mountbatten was commander of the destroyer *Kelly.* German bombers sank the ship in the Battle of Crete in 1941. Half the *Kelly's* crew of 240 was killed. The rest, including Mountbatten, clung to the wreckage for four hours under enemy fire before being rescued. In 1942, he became chief of combined operations. Mountbatten led a task force that planned raids on German-occupied areas in Europe. He took command of the Allied forces in Southeast Asia in 1943 and led the reconquest of Burma (now Myanmar) and Peninsular Malaysia from Japan.

Mountbatten was named viceroy of India in March 1947. He skillfully supervised the end of British rule in India in spite of deep rivalries among many of India's Hindu and Muslim inhabitants. The arrangement included the division of the country into the Hindu-dominated nation of India and the smaller Muslim-dominated nation of Pakistan. In August 1947, Mountbatten was chosen the first governor general of independent India. He returned to naval service in June 1948. Mountbatten was first sea lord from 1955 to 1959 and chief of the British defense staff from 1959 to 1965.

Mountbatten retired in 1965. He was killed when a bomb exploded his fishing boat off Ireland's coast. The Irish Republican Army, a terrorist group seeking Northern Ireland's independence from the British, claimed responsibility for the bombing. James L. Stokesbury

Mountbatten-Windsor. See Windsor (family).

Mounted Police. See Royal Canadian Mounted Police.

Mourning. See Funeral customs.

Mourning dove is an American bird with a sad, cooing call. It breeds in southeastern Alaska and from southern Canada to Mexico, and winters as far south as Panama. The bird is about 12 inches (30 centimeters) long. It flies swiftly, and its wings make a whistling sound as they move through the air.

WORLD BOOK illustration by Trevor Boyer, Linden Artists, Ltd.

The mourning dove has grayish-brown feathers. Its long tail tapers to a point and has a white border.

The mourning dove places its nest, built loosely of twigs, in a tree or bush or on the ground. The female lays two white eggs. The young hatch in about two weeks and leave the nest in about two more weeks. Young birds put their beaks in the parents' throats and feed on partly digested food mixed with a fluid called *crop milk.* Mourning doves eat weed seeds and insects.

Scientific classification. The mourning dove belongs to the pigeon and dove family, Columbidae. It is *Zenaida macroura.*

Edward H. Burtt, Jr.

Mouse is a small animal with soft fur, a pointed snout, round black eyes, rounded ears, and a thin tail. The word *mouse* is not the name of any one kind of animal or family of animals. Many kinds of *rodents* (gnawing animals) are called mice. They include small rats, hamsters, gerbils, jerboas, lemmings, voles, harvest mice, deer mice, and grasshopper mice. All these animals have chisellike front teeth that are useful for gnawing. A rodent's front teeth grow throughout the animal's life.

Facts in brief

Common name	Scientific name	Gestation period	Number of young	Where found
*House mouse	*Mus musculus*	18-21 days	4-7	Worldwide
American harvest mouse	*Reithrodontomys fulvescens*	21-24 days	1-7	North and South America
Grasshopper mouse	*Onychomys leucogaster*	29-38 days	3-4	North America
Deer mouse	*Peromyscus maniculatus*	21-27 days	1-9	North and South America

*The house mouse belongs to the family of Old World rats and mice, Muridae. The American harvest, grasshopper, and deer mice belong to the family of New World rats and mice, Cricetidae.

Cy La Tour

A house mouse eats stolen grain.

There are hundreds of kinds of mice, and they live in most parts of the world. They can be found in the mountains, in fields and woodlands, in swamps, near streams, and in deserts. Probably the best known kind of mouse is the house mouse. It lives wherever people live, and often builds its nest in homes, garages, or barns. Some kinds of white house mice are raised as pets. Other kinds are used by scientists to learn about sickness, to test new drugs, and to study behavior.

House mice

House mice probably could be found in the homes of people who lived during ancient times. Those mice probably stole the people's food, just as mice do today. The word *mouse* comes from an old Sanskrit word meaning *thief.* Sanskrit is an ancient language of Asia, where scientists believe house mice originated. House mice spread from Asia throughout Europe. The ancestors of the house mice that now live in North and South America were brought there by English, French, and Spanish ships during the 1500's.

House mice always seem to be busy. Those that live in buildings may scamper about day or night. House mice that live in fields and forests usually come out only at night. All house mice climb well and can often be heard running between the walls of houses.

Body of a house mouse is $2\frac{1}{2}$ to $3\frac{1}{2}$ inches (6.4 to 8.9 centimeters) long without the tail. The tail is the same length or a little shorter. Most house mice weigh $\frac{1}{2}$ to 1 ounce (14 to 28 grams). Their size and weight, and the length of their tails, differ greatly among the many varieties and even among individuals of the same variety.

The fur of most house mice is soft, but it may be stiff and wiry. It is grayish-brown on the animal's back and sides, and yellowish-white underneath. House mice raised as pets or for use in laboratories may have pure white fur, black or brown spots, or other combinations of colors. The tail is covered by scaly skin.

A house mouse has a small head and a long, narrow snout. Several long, thin whiskers grow from the sides of the snout. These whiskers, like those of a cat, help the mouse feel its way in the dark. The animal has rounded

ears, and its eyes look somewhat like round black beads. A mouse can hear well, but it has poor sight. Probably because house mice cannot see well, they may enter a lighted room even if people are there.

Like all other rodents, mice have strong, sharp front teeth that grow throughout the animal's life. With these chisellike teeth, mice can gnaw holes in wood, tear apart packages to get at food inside, and damage books, clothing, and furniture.

Food. A house mouse eats almost anything that human beings eat. It feeds on any meat or plant materials that it can find. Mice also eat such household items as glue, leather, paste, and soap. House mice that live out of doors eat insects, and the leaves, roots, seeds, and stems of plants. Mice always seem to be looking for something to eat, but they need little food. They damage much more food than they eat.

Homes. House mice live wherever they can find food and shelter. Any dark place that is warm and quiet makes an excellent home for mice. A mouse may build its nest in a warm corner of a barn, on a beam under the roof of a garage, or in a box stored in an attic or basement. The animal may tear strips of clothing or upholstery to get materials for its nest. It may line the nest with feathers or cotton stolen from pillows. House mice that live in fields or woodlands dig holes in the ground and build nests of grass inside. They may line the nests with feathers or pieces of fur.

Young. A female house mouse may give birth every 20 to 30 days. She carries her young in her body for 18 to 21 days before they are born. She has four to seven young at a time. Newborn mice have pink skin and no fur, and their eyes are closed. They are completely helpless. Soft fur covers their bodies by the time they are 10 days old. When they are 14 days old, their eyes open. Young mice stay near the nest for about three weeks after birth. Then they leave to build their own nests and start raising families. Most female house mice begin to have young when they are about 45 days old.

Enemies. People are probably the worst enemies of the house mouse. They set traps and place poisons where mice can easily find them. Almost every meat-eating animal is an enemy of house mice. Cats and dogs hunt mice in houses and barns. Coyotes, foxes, snakes, and other animals capture them in forests and woodlands. Owls, hawks, and other birds of prey swoop down on them in fields and prairies. Rats and even other mice are also enemies. House mice may live as long as a year in a hidden corner of an attic or basement. But they have so many enemies that few wild mice survive more than two or three months. Some mice kept as pets or in laboratories may live six years.

House mice avoid their enemies by hiding. A mouse seldom wanders far from its nest. It spends most of its time within an area of about 200 feet (61 meters) in diameter. Wherever possible, the mouse moves along paths protected by furniture, boxes, or other objects. The mouse scampers as fast as it can across the open spaces between the objects. House mice do not like water and try to avoid it, but they can swim.

Some other kinds of mice

American harvest mice look like house mice, but are smaller and have more hair on their tails. Most

White-footed mouse and her young

Jane Burton, Photo Researchers

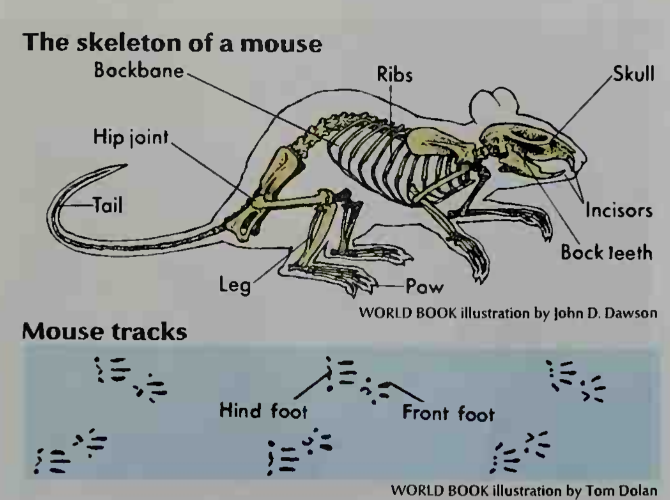
Harvest mouse

Grasshopper mouse

Cordell Andersen, NAS

American harvest mice also have much larger ears. Harvest mice live from southwestern Canada and the western half of the United States to Ecuador. They also live in the Eastern United States south of the Potomac and Ohio rivers. Some kinds of harvest mice live in salt marshes and in tropical forests, but most species prefer open grassy regions.

Harvest mice build their nests in places where tall grass grows. They weave leaves of grass into ball-shaped nests that are 6 to 7 inches (15 to 18 centimeters) in diameter. The mice build their nests 6 to 12 inches (15 to 30 centimeters) above the ground in branches of bushes or on stems of grass. Harvest mice are excellent climbers and use the plant stems as ladders to reach their nests. They grasp the plant stems with their tails as they climb. Harvest mice also make nests in the ground.



These mice eat green plant sprouts, but they prefer seeds. They pick seeds off the ground, or they "harvest" seeds from plants by bending the plant stems to the ground where they bite off the seeds.

A female harvest mouse has one to seven young at a time. She carries the young mice in her body for 21 to 24 days before they are born. When the young are about 2 months old, they may start their own families.

Grasshopper mice are about the same size as house mice, but they look fatter and have stubby tails. Their fur is brown or gray above and white underneath. They probably got their name because they eat grasshoppers. These mice are found in the dry regions and deserts of the Western United States, and in northern Mexico. Grasshopper mice live wherever they can find shelter in the ground. They often use burrows that were abandoned by such rodents as gophers, ground squirrels, and deer mice.

The female grasshopper mouse carries her young inside her body for 29 to 38 days. Usually three or four young are born at a time. The young mice become adults when they are about three months old.

Grasshopper mice are most active at night, when they come out of their burrows to hunt. Unlike most other mice, grasshopper mice prefer to eat meat rather than plants. They eat any animal they can overpower, including insects, worms, and other mice. Their favorite foods are grasshoppers and scorpions. Grasshopper mice hunt their prey much as cats do. They creep up to their victims and attack quickly. Grasshopper mice are the only mice that make howling noises at night.

WORLD BOOK illustration by John D. Dawson

WORLD BOOK illustration by Tom Dolan

A laboratory mouse is tested to determine its ability to learn in a simple *T maze, above.* Researchers place the mouse in the maze and time how long it takes to find the food. After a few repetitions, the mouse learns to find the food more quickly.

Deer mice, sometimes called *white-footed mice,* measure 6 to 8 inches (15 to 20 centimeters) long. Their tails are $2\frac{1}{2}$ to 4 inches (6 to 10 centimeters) long. The fur on their upper parts is gray or brown, and the belly fur is white. The ears of these mice are large in relation to the size of their bodies. There are more than 50 species of deer mice. They are found from northern Colombia throughout North America as far north as Alaska and Labrador. They live in every kind of region—mountains, plains, deserts, forests, and swamps.

Deer mice build their nests in tunnels they dig, or in hollow logs, tree stumps, or cracks in rocks. The mice may go into houses to find soft materials such as cloth or cotton for their nests. They usually build several nests a year because they move out when a nest gets soiled.

A female deer mouse gives birth to one to nine young at a time. She carries them in her body for 21 to 27 days before birth. The young live in the nest for three to six weeks, and then leave to build nests of their own.

Deer mice usually rest during the day and look for food at night. They eat berries, fruits, leaves, nuts, seeds, and insects. When excited, these mice thump their front feet rapidly on the ground. Clyde Jones

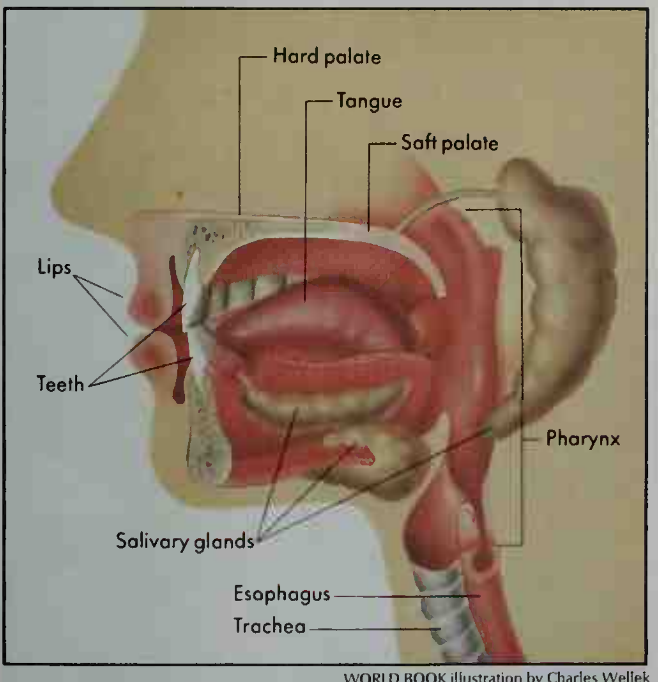
Mouse Tower is a tower on a small island in the Rhine River near Bingen, Germany. A famous legend tells that Archbishop Hatto of Mainz built the tower. According to the legend, during a famine in 974, the cruel archbishop lured the poor and needy of the town into a barn and then set it on fire. As the people shrieked among the flames, the archbishop called out, "Hear, hear how the mice squeak!" Soon afterward, a swarm of mice came to avenge the deaths. The bishop fled to the tower, but the mice swam across the Rhine and devoured him.

The city of Mainz had two archbishops named Hatto during the Middle Ages, but neither burned starving people in barns and neither was eaten by mice. *Mäuseturm,* the German name for the Mouse Tower, appears to be a form of *mautturm,* which means *toll tower.* The tower was probably built in the 1200's as a place for collecting tolls from boats on the Rhine. C. Stephen Jaeger

Mousorgski, Modest. See Mussorgsky, Modest.



Mouth is the part of the body that is adapted for taking in food. The lips at the mouth opening help us drink and

pick up our food. Inside, we have two rows of teeth, one above the other, to grind and crush food into pulp that can be swallowed and digested. Salivary glands in the walls and floor of the mouth give off saliva, which mixes with our food as we chew it. Saliva helps us swallow dry foods and aids digestion of sugars. See Saliva.

The mouth cavity is lined with mucous membrane. The roof of the mouth consists of a bony front part, called the *hard palate,* and a soft part in the rear, called the *soft palate.* The hard palate forms a partition between the mouth and nasal passages. The soft palate arches at the back of the mouth to form a curtain between the mouth and *pharynx* (back part of the throat). During swallowing, the soft palate closes the nasal passages from the throat to prevent food from entering the nose. The pharynx connects the mouth and nose with both the *esophagus* (tube that carries food to the stomach) and the *trachea* (windpipe that carries air to the lungs). A flexible bundle of muscles extends from the floor of the mouth to form the *tongue.* The tongue not only helps us to eat, swallow, and talk, but it contains almost all the sense organs of taste (see Taste).

Harmful germs may enter the body through the mouth. The mouth should be kept clean to help ward off disease. The mouth cavity is an excellent breeding place for germs because it is warm and moist.

The teeth should be cleaned thoroughly at least twice a day, and the mouth should be rinsed out after every meal. The teeth should be brushed lengthwise as well as crosswise, to remove particles of food. Jagged teeth may damage the mucous membrane and lead to infection. *Periodontitis* (diseased gums) causes bone loss around the teeth, which may eventually make teeth become loose and fall out. Disease of the teeth may cause the body to become infected by bacteria. Trench mouth, also called *Vincent's infection,* is an infection of the mouth. Painful cankers may also attack the mucous membrane that lines the mouth. Raymond L. Burich

WORLD BOOK illustration by Charles Wellek

The mouth is adapted for taking in food. Food is ground by the teeth, and moistened and partly digested by saliva. The tongue tastes and mixes the food and aids in swallowing. The tongue, teeth, and lips also help form the sounds of human speech.

Mowat, *MOW uht,* **Farley** (1921-), is a Canadian author who has written widely about the wildlife and peoples of northern Canada. In many of his books, Mowat tells captivating stories that also explore serious ecological and conservation issues.

Mowat was born in Belleville, Ontario. His first book, *People of the Deer* (1952), describes the life of the deer-hunting Ihalmiut, an Inuit people whose population had declined from 7,000 in 1890 to 40 in 1949. The book criticizes the Canadian government for policies that led to the destruction of the Ihalmiut and their way of life. Mowat's *Never Cry Wolf* (1963) portrays a young biologist who studies wolves in the northern wilderness. This book argues that wolves are not vicious animals but play a necessary and useful role in nature. Other books by Mowat that deal with wildlife issues include *A Whale for the Killing* (1972) and *Sea of Slaughter* (1984).

Mowat also wrote the biography *Woman in the Mists: The Story of Dian Fossey and the Mountain Gorillas of Africa* (1987). This book became the basis for the movie *Gorillas in the Mist* (1988). Rosemary Sullivan

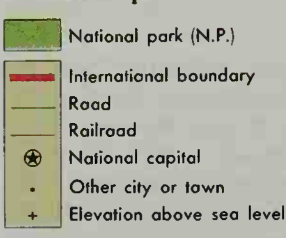
Mowat, Sir Oliver (1820-1903), a Canadian statesman, served as prime minister and attorney general of Ontario from 1872 to 1896. During his administration, Mowat introduced the ballot in municipal and provincial elections and extended the voting franchise. He fought to obtain more political rights for the provinces.

Mowat was also one of Canada's Fathers of Confederation. These individuals were planners of the union of British colonies that formed the Dominion of Canada in 1867. Mowat was knighted in 1892. He was lieutenant governor of Ontario from 1897 until his death. He was born in what is now Kingston, Ontario.

David Jay Bercuson

Moynihan, Daniel Patrick (1927-), a Democrat from New York, served in the United States Senate from 1977 to 2001. He was chairman of the Senate Finance Committee from 1993 to 1995.

An authority on the problems of cities and of minority groups, Moynihan first became known for his writings on immigration, the antipoverty program, and black family life. From 1966 to 1969, he headed the Joint Center of Urban Studies at Harvard University and Massachusetts Institute of Technology. He served as counselor to the president under Richard M. Nixon in 1969 and 1970. Moynihan returned to Harvard in 1971 as professor of education and urban politics. He remained on the faculty until 1976. Moynihan served as the nation's ambassador to India from 1973 to 1975. In 1975 and 1976, he served as U.S. ambassador to the United Nations.



Moynihan was born in Tulsa, Oklahoma, but grew up in New York City. He graduated from Tufts University and received a doctorate from the Fletcher School of Law and Diplomacy at Tufts. He was an assistant to Governor Averell Harriman of New York in the 1950's and served in the U.S. Department of Labor from 1961 to 1965. David S. Broder

Mozambique, *MOH zuhm BEEK,* is a country on the southeast coast of Africa. The country is noted for its many fine harbors. Its port facilities are used by some neighboring countries. Maputo is the country's capital, largest city, and chief port. Mozambique was governed by Portugal from the early 1500's until 1975, when it became independent after a 10-year struggle against Portuguese rule.

Government. The president of Mozambique is the head of state and head of government. The people elect the president to a five-year term. The president appoints a prime minister and cabinet. The prime minister heads the cabinet, which is called the Council of Ministers.

The elected Assembly of the Republic makes Mozambique's laws. Its 250 members serve five-year terms. The two largest political parties are commonly called Frelimo and Renamo. Frelimo was originally an organization opposed to Portuguese rule. Its full name is the Front for the Liberation of Mozambique. Renamo's full name is the Mozambican National Resistance.

Mozambique

Facts in brief

Capital: Maputo.
Official language: Portuguese.
Official name: República de Moçambique (Republic of Mozambique).
Area: 309,496 mi² (801,590 km²). *Greatest distances*—east-west, 680 mi (1,094 km); north-south, 1,100 mi (1,770 km). *Coastline*—1,556 mi (2,504 km).
Elevation: *Highest*—Mount Binga, 7,992 ft (2,436 m) above sea level. *Lowest*—sea level.
Population: *Estimated 2002 population*—20,367,000; population density, 66 per mi² (25 per km²); distribution, 72 percent rural, 28 percent urban. 1997 census—16,099,246.
Chief products: Cashews, cassava, coconuts, cotton, shrimp, sugar cane.
Flag: The flag has three broad, horizontal stripes of green, black, and yellow separated by narrow white bands. To the left is a red triangle with a yellow star. The star holds a book with a hoe and rifle crossed over it. See Flag (picture: Flags of Africa).
Money: *Basic unit*—metical. One hundred centavos equal one metical.

Mozambique is divided into 11 provinces. The Supreme Court is the country's highest court.

People. Almost all Mozambicans are black Africans. Other groups, including people of Arab, European, and Indian descent, make up less than 1 percent of the population. Most of the black people belong to groups that speak one of the Bantu languages. The largest group, the Makua-Lomwe, accounts for about 40 percent of the population of Mozambique. Only a few black people can speak Portuguese, the country's official language. Some Mozambicans speak English in business activities.

Most Mozambicans are farmers, but their techniques are extremely simple. Some farmers use the *slash-and-burn* method, which involves cutting and burning forest

trees to clear an area for planting. Farmers in some areas of the country use more modern techniques.

About 55 percent of the people of Mozambique practice traditional African religions. Many of this group are *animists,* who believe that everything in nature has a soul. Others worship the spirits of their ancestors. About 25 percent of the people are Christians, mostly Roman Catholics. About 15 percent of the people are Muslims.

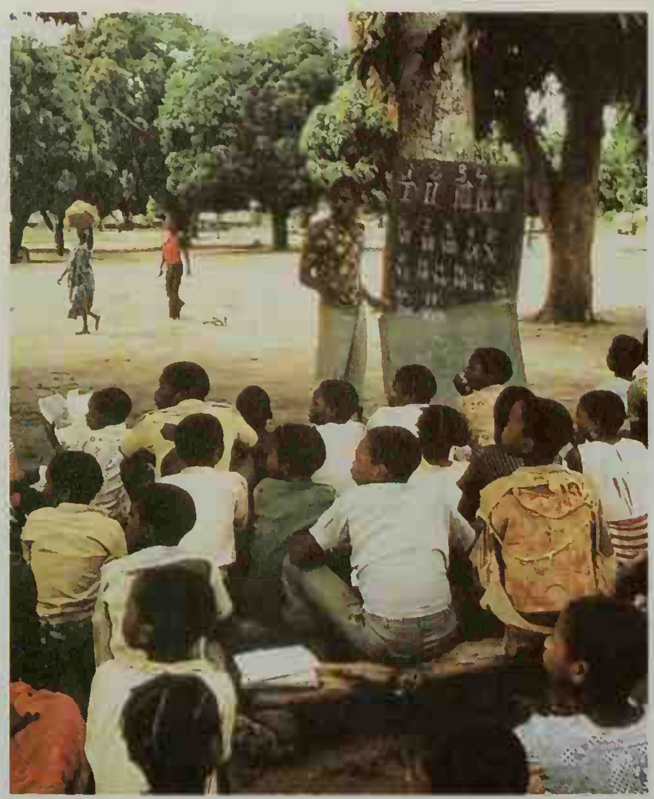
A majority of Mozambicans cannot read and write. But government programs have begun to improve education. For Mozambique's literacy rate, see **Literacy** (table). A university was established in Maputo in 1962.

Land and climate. Almost half of Mozambique is covered by a flat plain that extends inland from the coast. The land rises steadily beyond the plain, and high plateaus and mountains run along much of the western border. Sand dunes and swamps line the coast. Grasslands and tropical forests cover much of the country.

Many sizable rivers flow east through Mozambique into the Indian Ocean, and their basins have extremely fertile soil. Cashew trees and coconut palms grow throughout the country. Animal life in Mozambique includes crocodiles, elephants, lions, and zebras.

Mozambique has a basically tropical climate, but temperatures and rainfall vary considerably in different areas. Temperatures average 68 °F (20 °C) in July and 80 °F (27 °C) in January. About 80 percent of the annual rainfall occurs from November to March. The rainfall ranges from 16 to 48 inches (41 to 122 centimeters).

Economy of Mozambique is not well developed. Agriculture is Mozambique's major economic activity. The nation is a leading producer of cashews. Other crops include coconuts, cotton, sugar cane, and *cassava,* a starchy root. Some people catch fish and shrimp in the Indian Ocean. The economy depends partly on payments by neighboring countries for the use of railroads and port facilities. Maputo and Beira are the chief ports.



Industrial development has been slow and has occurred mainly in the food-processing and oil-refining industries. Coal is mined in central Mozambique. The Cahora Bassa Dam in the northwest produces electric power, much of which is transmitted to South Africa.

Most of Mozambique's roads are unpaved. Several railroads link Mozambican ports with other African countries. The chief airport is at Maputo.

History. People have lived in what is now Mozambique since around 4000 B.C. Bantu-speaking people settled there before A.D. 100. Arabs lived in the area by the 800's. Portuguese explorers first visited Mozambique in 1497. They established a trading post there in 1505, and the country became a slave-trading center. But most of Mozambique was undeveloped until the 1900's.

Through the years, Portuguese control of Mozambique was threatened by Arabs, Africans, and some European nations. In 1885, Africa was divided among various European powers, and Mozambique was recognized as a Portuguese colony. It was often called Portuguese East Africa. Borders similar to those of present-day Mozambique were established in 1891.

Towns and railroads were built in Mozambique during the late 1800's and early 1900's, and the Portuguese population rose. In the 1950's, many black people became increasingly discontented with white Portuguese rule. Frelimo was established in 1961 as a guerrilla movement. It began military attacks against the Portuguese in 1964 and gained control of part of northern

Mozambique. Fighting continued for 10 years.

Portugal agreed in 1974 to grant independence to its colonies. Mozambique became independent on June 25, 1975. Frelimo took over the government, and Samora Machel became the first president. Most of the Portuguese then left Mozambique. Frelimo, at that time a socialist party, began putting major industries under government control. Frelimo also introduced improvements in health care and education.

In 1976, Mozambique closed its border with Rhodesia (now Zimbabwe) in cooperation with United Nations sanctions against that country's white minority government. This action cost Mozambique much income from Rhodesian use of its railroads and ports. Many black Rhodesians fled to Mozambique to use bases there in their fight against the Rhodesian government. In 1980, black people gained control of Rhodesia's government, and the country's name was changed to Zimbabwe.

Mozambique also aided guerrilla forces that opposed the white minority government in South Africa. South Africa gave aid to guerrillas fighting against Mozambique's government. In 1984, the two countries signed a treaty in which they agreed to stop aiding the guerrillas. But the guerrillas in Mozambique, called the Mozambican National Resistance (Renamo), continued fighting there. The fighting disrupted farming and other economic activities. In 1986, Machel was killed in a plane crash, and Joaquim Chissano became president. In 1994, a multiracial government gained control of South Africa.

In the 1980's, Mozambique's government decided to permit the increase of private enterprise. It helped people start their own businesses and began a shift from government-run farms to private and family-run farms.

In the 1980's and early 1990's, droughts and the disruption resulting from the war with Renamo caused food shortages that led to malnutrition and starvation for millions of people. Frelimo and Renamo signed a peace agreement in 1992. Frelimo had been Mozambique's only legal political party until 1990, when a new constitution was adopted. New parties began to register legally in 1992. Mozambique held its first multiparty election in 1994. Chissano won the presidential election. He was reelected president in 1999.

In 2000, Cyclone Eline and heavy rains struck Mozambique, causing widespread flooding. About 700 people died, and about 500,000 were left homeless. Severe floods again struck in 2001, killing about 100 people and leaving more than 200,000 homeless. Kathleen Sheldon

Mozart, *MOHT sahrt,* **Wolfgang Amadeus,** *AM uh DAY uhs* (1756-1791), an Austrian composer, is considered one of the greatest and most creative musical geniuses of all time. With Joseph Haydn, he was the leading composer of the Classical style of the late 1700's. Mozart died before his 36th birthday, but he still left more than 600 works.

His life

Mozart was born in Salzburg. His father, Leopold, was the leader of the local orchestra, and also wrote an important book about violin playing. At the age of 3, Wolfgang showed signs of remarkable musical talent. He learned to play the harpsichord, a keyboard instrument that preceded the piano, at the age of 4. He was composing music at 5, and when he was 6, he played for the Austrian empress at her court in Vienna.

Before he was 14, Mozart had composed many works for the harpsichord, piano, or the violin, as well as orchestral and other works. His father recognized Wolfgang's amazing talent and devoted most of his time to his son's general and musical education. While serving as his teacher, Leopold took Wolfgang on concert tours through much of Europe. Wolfgang composed, gave public performances, met many musicians, and played the organ in many churches. In 1769, like his father before him, he began working for the archbishop of Salzburg, who also ruled the province. The Mozarts often quarreled with the archbishop, partly because Wolfgang was often absent from Salzburg. The archbishop dismissed young Mozart in 1781.

Mozart was actually glad to leave Salzburg, a small town, and seek his fortune in Vienna, one of the music capitals of Europe. By this time people took less notice of him, because he was no longer a child prodigy. But he was a brilliant performer and active as a composer.

Mozart married in 1782. He earned a living in Vienna by selling his compositions, giving public performances, and giving music lessons. None of these produced enough income to support his family. Mozart even traveled to Germany for the coronation of a new emperor, but his concerts there did not attract as much attention as he hoped. Mozart died in poverty on Dec. 5, 1791.

His works

Operas. Mozart excelled in almost every kind of musical composition. Several of his 22 operas gained wide

recognition before and after his death, and they still please audiences all over the world. *The Marriage of Figaro* (1786) and *Don Giovanni* (1787) are operas Mozart composed with words in Italian. *The Magic Flute* (1791) has German texts. Each of these operas contains *arias* (songs for single voices), *recitative* (rapidly sung dialogue), *ensembles* in which several people sing at the same time, and choruses. The orchestra provides an ever-changing expressive accompaniment. The drama ranges from comedy to tragedy.

Symphonies. Mozart wrote over 40 symphonies, many of which are performed today. Some originally were *overtures* (orchestral introductions) for operas, and last only a few minutes. His later symphonies, which are the most popular, are full-length orchestral compositions that last 20 to 30 minutes. Most consist of four *movements* (sections). His last and most famous symphony, Number 41 (1788), is nicknamed the *Jupiter*.

Church music. Mozart composed a great amount of church music, most of it for performance at the Salzburg Cathedral. He wrote Masses and shorter pieces called *motets;* and he set psalms to music, especially for the vespers (afternoon or evening) service. The music is beautiful and varied. It includes choral and solo parts, usually with accompaniment by organ and orchestra. Mozart's best-known sacred work is the *Requiem* (Mass for the Dead). He began it in 1791 and while writing it seems to have become concerned about his own death. Parts of the *Requiem* were composed during his final illness. He died before the work was finished.

Other works. Mozart wrote other, generally lighter, orchestral works called *serenades*. Some of these were intended for outdoor performance. One has become well known as *Eine kleine Nachtmusik* (A *Little Night Music,* 1787). Mozart also wrote many compositions called *concertos* for a solo instrument such as violin or piano, with orchestral accompaniment. He often played the solo part.

Throughout his life Mozart composed *chamber music*—works for a small number of instruments in which only one musician plays each part. Mozart concentrated on string quartets (two violins, viola, and cello). He was influenced in this by Haydn, whose quartets he admired, and to whom he dedicated six quartets.

Mozart's sonatas for keyboard (harpsichord or piano) and for violin and keyboard are outstanding. The piano was then still fairly new and was widely played by amateurs. More than any other composer, Mozart helped to make the instrument popular.

His style. In spite of his hardships and disappointments, much of Mozart's music is cheerful and vigorous. He had a sense of humor and liked puns and practical jokes. He composed many lighter works. These works include the opera *Così Fan Tutte (All Women Are Like That,* 1790), much of his early instrumental music, and *canons* (rounds) with nonsense words.

Mozart also produced deeply serious music. His most profound works include his late piano concertos, several string quartets, the string quintet in G minor, and his last three symphonies—E flat major, G minor, and the *Jupiter*. Larger works contain both serious and light elements, as does *Don Giovanni*.

Mozart belonged to the Order of Freemasons and wrote several compositions for their meetings. Some

A Mozart family portrait from about 1780 shows the young Wolfgang seated next to his sister, Nannerl, who was a noted pianist. Their father, Leopold, *right,* gained recognition as a violinist and composer. A portrait of Wolfgang's mother, Anna Maria, hangs on the wall.

scenes from his fairy-tale opera *The Magic Flute* were inspired by Masonic traditions and beliefs.

A catalog of Mozart's works was first prepared in the 1800's by Ludwig Köchel, a German music lover. Mozart's works are still identified by the numbers Köchel assigned to them. A famous music and theater festival held each summer in Salzburg features Mozart's works.

Mubarak, *muh BAHR ak,* **Hosni,** *HAHS nee* (1928-), became president of Egypt in October 1981. He succeeded Anwar el-Sadat, who was assassinated by Islamic fundamentalist extremists. As president, Mubarak continued Sadat's policies, including the fulfillment of the 1979 peace agreement between Egypt and Israel (see **Egypt** [Recent developments]). Mubarak faces strong opposition from Islamic extremists in Egypt, who also challenged Sadat's policies and Egypt's negotiations with Israel.

State Information Service of Egypt
Hosni Mubarak

In August 1990, Iraq invaded and occupied Kuwait. Mubarak played a leading role in organizing Arab opposition to Iraq. Egypt and other Arab nations and the United States and other Western nations formed a military coalition against Iraq. In February 1991, the coalition drove the Iraqis out of Kuwait. See **Persian Gulf War.**

Violence by Islamic extremists increased greatly in the early 1990's in Egypt. These people attacked Egyptian Christians, foreign tourists, and other foreigners. In 1992, Mubarak's government began raiding extremist strongholds and making arrests.

Mubarak was born on May 4, 1928, in Kafr-El-Meselha, a village about 80 miles (130 kilometers) north of Cairo. He graduated from Egypt's Military Academy in 1949 and its Air Force Academy in 1950. He then served as a fighter pilot and a bomber squadron commander in the Egyptian Air Force. Mubarak commanded the air force from 1972 to 1975, when Sadat appointed him vice president. Malcolm C. Peck

Mubarak, *muh BAHR ak,* **Suzanne** (1942-), is a leading Egyptian supporter of women's and children's rights and children's literacy. Her work focuses on children and women in Egypt, but she also works with the United Nations (UN) and other international organizations. She is the wife of Egyptian President Hosni Mubarak.

Suzanne Thabet was born in Al Minya Governorate, Egypt. She married Hosni Mubarak in 1959. She received a bachelor's degree in political science at the American University in Cairo, Egypt, in 1977. That same year, she established the Integrated Care Society, an organization that provides various social, cultural, and health-care services to children in Egypt.

In 1982, Mubarak received a master's degree in sociology, again from the American University. In 1991, she began a national campaign that encourages both youngsters and adults to read. Through the years, she has participated in a number of international conferences on children and women, including the 1994 World Health Organization (WHO) Task Force on Health and Development Policies and the 1995 UN Fourth World Conference on Women. Today, she serves as president of the Egyptian National Women Committee and chairperson of the Advisory Board to the National Council on Childhood and Motherhood. Howard Timms

Mucilage, *MYOO suh lihj,* is a thick, sticky substance usually made by dissolving gum in water or in some other liquid. The purpose of mucilage is to cause two substances to *adhere* (stick together). Therefore, mucilage is classified as an *adhesive.* The exact ingredients of mucilage vary with the adhesive's planned uses. Gum arabic dissolved in hot water makes gum-arabic mucilage. When aluminum sulfate is added to the solution, the adhesive may be used to make paper stick to glass. Dissolving *dextrin* (a substance made from starch) in cold water makes a mucilage that is used on postage stamps. Glue and gelatin also are used to make mucilage. See also **Glue; Gum arabic.** James Nelson Rieck

Muckrakers were a group of writers in the early 1900's who exposed social and political evils in the United States. They wrote about such problems as child labor, prostitution, racial discrimination, and corruption in business and government. In 1906, President Theodore Roosevelt labeled them *muckrakers* because he felt they were concerned only with turning up filth. But these writers increased public awareness of social problems and forced government and business to work to solve them.

Nearly all the muckrakers were journalists who wrote for inexpensive monthly magazines, including *American Magazine, Collier's, Cosmopolitan, Everybody's Magazine,* and *McClure's Magazine.* Some historians and novelists were also called muckrakers.

Muckraking gained much support from the public after *McClure's* published three exposés in 1903. The articles included investigations of corrupt city government by Lincoln Steffens and of the Standard Oil Company by Ida M. Tarbell. Many articles by muckrakers later appeared as books, including *The Shame of the Cities* (1904) by Steffens and *History of the Standard Oil Company* (1904) by Tarbell. Other prominent muckrakers were Samuel Hopkins Adams, Ray Stannard Baker, Charles E. Russell, and Upton Sinclair.

The muckrakers helped prepare the way for many reforms in the United States. Sinclair's novel *The Jungle* (1906) exposed unsanitary conditions in the meatpacking industry and led to the nation's first pure food laws. Other reforms included the direct election of U.S. senators and greater government regulation of business. Muckraking disappeared by about 1912, partly because the public lost interest. David Chalmers

Mucus, *MYOO kuhs,* is a thick, clear, slimy fluid found in the nose, mouth, and other organs and passages that open to the outside of the body. It is made up mostly of a compound of protein and sugar. This fluid is produced by cells in the mucous membranes and covers the surfaces of the membranes. Mucus provides lubrication for material which must pass over the membranes, such as food passing down the *esophagus* (food tube). It also catches foreign matter and keeps it from entering the body. See also **Cold, Common; Cystic fibrosis; Membrane; Mouth; Nose.** Jerome C. Goldstein

Mudd, Samuel Alexander (1833-1883), was the doctor who set John Wilkes Booth's leg after Booth assassinated United States President Abraham Lincoln in 1865. Mudd claimed he did not recognize Booth. A military court found Mudd guilty as an accessory after the fact in the assassination. Sentenced to life imprisonment, Mudd saved many prisoners and guards in a yellow fever epidemic. In 1869, he was pardoned by President Andrew Johnson and freed from prison. Mudd was born on Dec. 20, 1833, in Charles County, Maryland. Mark E. Neely, Jr.

Mudpuppy is a large salamander that lives in American ponds, streams, lakes, and rivers. It may grow as much as 17 inches (43 centimeters) long, but an 8-inch (20-centimeter) animal may be full-grown.

The mudpuppy has a slimy body. It may be dark brown, gray-brown, or black, usually with darker spots. It has a powerful flat tail and four weak legs. It has deep purplish-red external gills behind its short, flat head.

E. R. Degginger

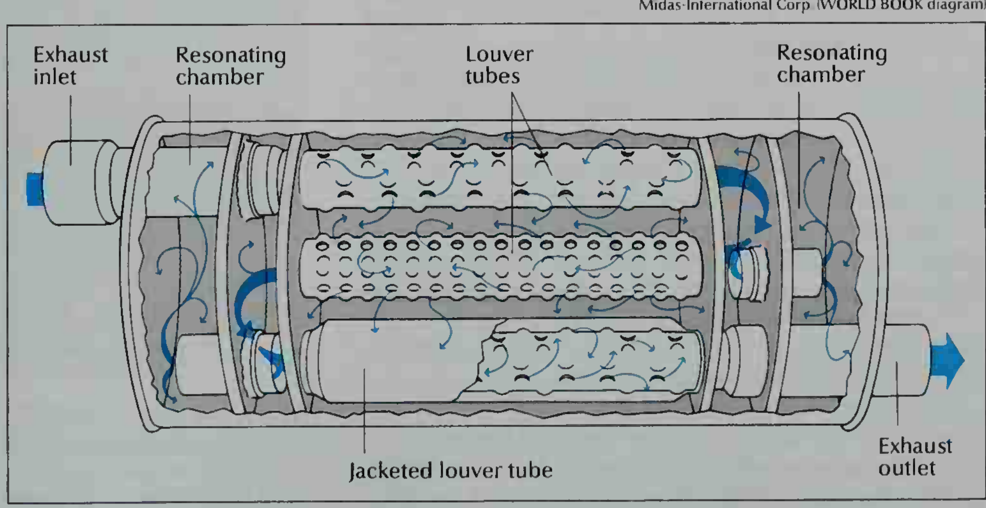
The mudpuppy is a type of salamander. It has a powerful flat tail and four weak legs. It lives in American ponds and streams.

Mudpuppies live in the Great Lakes, the Mississippi River, and ponds and streams as far south as Georgia and as far west as Texas. Mudpuppies usually stay in 2 to 8 feet (0.6 to 2.4 meters) of fresh water, especially among water plants. They attach their yellow eggs to some object lying under about 4 feet (1.2 meters) of sunny water. Mudpuppies eat crayfish, fish eggs, and other water animals. They usually hunt during the hours of dawn or dusk. Don C. Forester

Scientific classification. The mudpuppy is in the family Proteidae. The most common mudpuppy is *Necturus maculosus.*

Muffler is a device that greatly reduces the exhaust noise of an engine. Mufflers are used on nearly all automobiles. The exhaust of a gasoline engine originates in the cylinders. When the exhaust leaves the cylinders, it is at a much higher temperature and pressure than the outside air (see **Gasoline engine**). If released directly into the air from the cylinders, the exhaust would expand suddenly, producing a loud, sharp noise. In the muffler and in other parts of the exhaust system, the gases are allowed to expand gradually and to cool. The pressure is thereby reduced, and little noise results when the exhaust is released. William H. Haverdink

Mugabe, *moo GAH bay,* **Robert Gabriel** (1924-), became head of the government of Zimbabwe in 1980. Mugabe heads the country's largest and most powerful political party, the Zimbabwe African National Union-Patriotic Front (ZANU-PF). During the 1970's, Mugabe helped lead the country's black nationalists in a military and political struggle to end white-minority rule.



Mugabe became prime minister after ZANU-PF won parliamentary elections in February 1980. Zimbabwe became an independent country in April 1980. During the 1980's, Mugabe worked to establish a one-party socialist state. In 1987, the office of prime minister was replaced with the office of executive president, and Mugabe was elected to the new office. In 1989, ZANU-PF merged with its rival, the Zimbabwe African People's Union, and the new party adopted the name ZANU-PF. In 1990, ZANU-PF rejected Mugabe's proposal for creating a one-party state. Mugabe was reelected executive president in 1990, 1996, and 2002. Many people have criticized Mugabe for his attempts to achieve absolute power and for his government's intimidation of opposition groups and the media in Zimbabwe.

Mugabe was born in Kutama, near what is now

How a muffler works

A muffler reduces the noise made by exhaust gases from a gasoline engine. The device passes the gases through perforated pipes called *louver tubes.* These tubes enable the gases to expand and cool so that the gases do not produce a loud noise when they reach the outside air. *Resonating chambers* also help deaden exhaust noise by absorbing some of the sound produced by the gases as they flow through the muffler.

Midas-International Corp. (WORLD BOOK diagram)

Harare, Zimbabwe. In 1963, he helped found ZANU-PF. The white-minority government of Zimbabwe jailed him from 1964 to 1974. Sanford J. Ungar

Mughal Empire, *MOO guhl,* also called the Mogul Empire, ruled most of India in the 1500's and 1600's. Life in Mughal India set a standard of magnificence for its region of Asia, and the empire had order and stability. The centralized government of the empire provided a model for later rulers of India. A distinctive culture developed that blended Persian and Indian elements, and the Persian language became widely used.

Babur, a prince from central Asia, founded the Mughal Empire in 1526. His grandson Akbar established its governmental structure. Akbar, who ruled from 1556 to 1605, controlled most of what are now north and central India, Afghanistan, Bangladesh, and Pakistan. Jahangir, Akbar's son, ruled from 1605 to 1627 and was a patron of Persian culture. His son Shah Jahan reigned from 1628 to 1658. He encouraged architecture and built the famous Taj Mahal as a tomb for his wife. Shah Jahan's son Aurangzeb took the throne from his father in 1658. Aurangzeb attempted to expand the empire and to control rebellions within it.

The Mughal emperors were Muslims who ruled a largely Hindu nation. Under Akbar, some Hindu warriors served as Mughal generals and governors. Other Hindus were administrators and clerks. Later, Aurangzeb reimposed a tax on the Hindus that had been abolished by Akbar and destroyed many of their temples. The Marathas, Hindu warriors of western India, revolted and seriously weakened the empire.

The Mughal Empire began to break up soon after Aurangzeb's death in 1707. Mughals continued to rule a declining kingdom centered at Delhi until Britain deposed the last emperor in the mid-1800's. Patricia Risso

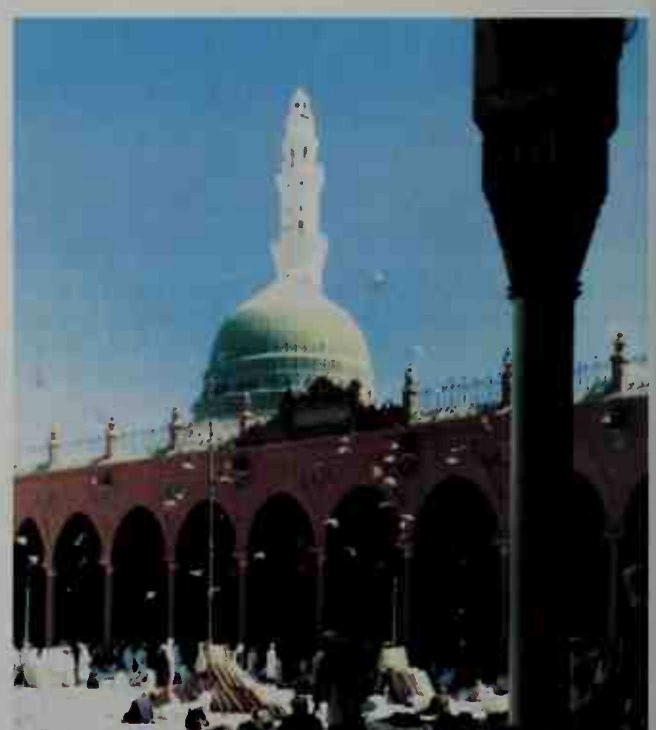
Mugwumps were influential Republicans who refused to support their party's presidential candidate, James G. Blaine, in 1884. The Mugwumps, who supported government reform, did not trust Blaine and believed he opposed reform. They worked for the Democratic candidate, Grover Cleveland. In the election, Cleveland narrowly defeated Blaine. See also **Cleveland, Grover** (Election of 1884). Robert W. Cherny

Muhammad, *moo HAM uhd* (A.D. 570?-632), was a prophet whose life and teachings form the basis of the Islamic religion. The name *Muhammad* means *Praised One.* There are several common spellings of the name, including *Mohammad, Mohammed,* and *Mahomet.* Muslims believe Muhammad was the last messenger of God. They believe he completed the sacred teachings of such earlier prophets as Abraham, Moses, and Jesus. Muslims respect Muhammad but do not worship him.

Muhammad was one of the most influential men of all time. He felt himself called to be God's prophet. This belief gave him the strength to bring about many changes in Arabia. When Muhammad began to preach in the 600's, Arabia was a wild, lawless land. The fierce tribes of the deserts fought continual bloody wars.

In Mecca, a city in southwestern Arabia, there was much suffering among the poor. Most of the people worshiped many gods, and prayed to idols and spirits.



Muhammad brought a new message to his people from God. He taught that there is only one God, and that this God requires people to make *Islam* (submission) to Him. Muhammad replaced the old loyalty to tribes with a new tie of equality and allegiance among all Muslims. He also preached against the injustice of the wealthy classes in Mecca, and tried to help the poor.

During his lifetime, Muhammad led his people to unite in a great religious movement. Within a hundred years after his death, Muslims carried the teachings of Muhammad into other parts of the Middle East, into northern Africa, Europe, and Asia.

Early life. Muhammad was born in Mecca. His father died before his birth, and his mother died when he was a child. His grandfather, and later Abu Talib, his uncle, became his guardians. For a time, Muhammad lived with a desert tribe. He learned to tend sheep and camels. According to tradition, he joined his uncle on caravan journeys through Arabia to Syria. He probably attended assemblies and fairs in Mecca, where he may have heard people of different faiths express their ideas.

At the age of 25, Muhammad entered the service of Khadija, a wealthy widow of about 40. He later married her. They had two sons and four daughters. The sons died young. One daughter, Fatima, married Ali, son of Abu Talib. Many Muslims trace their descent from Muhammad through this couple (see **Fatimid dynasty**).

His religious life. The most sacred shrine in Mecca was the Kaaba. It had a black stone, believed to be especially sacred, in one corner. When Muhammad was 35, a flood damaged the Kaaba. Because of his moral excellence, Muhammad was chosen to set the sacred stone back into place (see **Kaaba**). Later, when Muhammad was meditating alone in a cave on Mount Hira, a vision appeared to him. Muslims believe the vision was of the

The burial place of Muhammad is the Prophet's Mosque in Medina, Saudi Arabia, shown here. Muhammad died in Medina in A.D. 632. He had fled there from Mecca in 622. Most Muslims who make a yearly pilgrimage to Mecca visit this mosque.

angel Gabriel, who called Muhammad to serve as a prophet and proclaim God's message to his people.

At first, Muhammad doubted that his vision had come from God. But his wife Khadija reassured him. She became his first disciple. For a time, no more revelations came, and Muhammad grew discouraged. Then Gabriel came again, and told him, "Arise and warn, magnify thy Lord ... wait patiently for Him." At first, Muhammad may have told only relatives and friends of the revelations. But soon he began to preach publicly. Most people who heard him ridiculed him, but some believed. Abu Bakr, a rich merchant, became a disciple. Umar, a Meccan leader, persecuted Muhammad at first, but later accepted him as a prophet.

The Hijra. Muhammad continued to preach in Mecca until several calamities took place. First, both Khadija and Abu Talib died. Also, the people of Mecca began to hate Muhammad for his claims and his attacks on their way of life. Finally, in A.D. 622, Muhammad fled north to the nearby city of Medina, then called Yathrib. His emigration to Medina is called the *Hijra,* also spelled *Hegira.* It is considered so important that the Muslim calendar begins with the year of the Hijra. The people of Medina welcomed Muhammad. His preaching and statesmanship soon won most of them as followers.

His teachings. Muhammad was now the head of both a religion and a community, and he made his message law. He abolished idol worship and the killing of unwanted baby girls. He limited *polygyny* (marriage to more than one wife at a time) and restricted divorce. He reformed inheritance laws, regulated slavery, and helped the poor. He also banned war and violence except for self-defense and for the cause of Islam.

Muhammad seems to have expected Jews and Christians to accept him as a prophet. At first he was friendly toward them. He chose Jerusalem as the direction to be faced in prayer, similar to the Jewish practice. He also set aside Friday as a Muslim day of congregational prayer, perhaps because the Jews began their Sabbath preparations then. But the Jews were hostile to him and his followers. Muhammad drove the Jews from the city of Mecca and organized a purely Muslim society. To symbolize the independence of the new religion, he redirected his followers to face Mecca, instead of Jerusalem, when praying.

The Meccans went to war against Muhammad and his followers. They attacked Medina several times but were always driven back. In 630, Muhammad entered Mecca in triumph. He offered pardon to the people there, most of whom accepted him as the Prophet of God. He destroyed the pagan idols in the Kaaba, prayed there, and made it a *mosque* (house of worship). Muhammad died two years later in Medina. His tomb is in the Prophet's Mosque in Medina (see **Medina**). Charles J. Adams

Muhammad, *moo HAM uhd,* **Elijah,** *ih LY juh* (1897-1975), was the major leader of the original Nation of Islam, whose members called themselves Black Muslims. This organization combined religious beliefs with black nationalism. Muhammad favored racial separation and wanted to establish a black nation within the United States.

Muhammad was born on Oct. 10, 1897, in Sandersville, Georgia. His given and family name was Elijah Poole. In 1923, he moved to Detroit, where he worked on an automobile assembly line. In 1930, he met the founder of the Black Muslims, Wallace D. Fard (or Wali Farad). Fard eventually chose this devoted disciple as his chief aide and gave him the Muslim name Muhammad.

After Fard disappeared in 1934, Muhammad led a number of Black Muslims to Chicago, where he established the organization's main headquarters. He also set up the worship of Fard as Allah and himself as the Messenger of Allah and head of the Black Muslims. Muhammad built on the teaching of Fard and combined aspects of Islam with the black nationalism of leader Marcus Garvey. Aided by his chief disciple, Malcolm X, Muhammad built the movement and encouraged its rapid spread in the 1950's and 1960's. Lawrence H. Mamiya

Muhammad Ali, the boxer. See **Ali, Muhammad**.

Muhammad Ali, *moo HAM uhd AH lee* (1769-1849), ruled Egypt from 1805 to 1848. He used French and other European advisers to help modernize Egypt and to increase its wealth and power. Under him, the Egyptian government and army came to be patterned after those of European countries. However, Muhammad Ali did not encourage democracy. He kept power firmly in his own hands.

Muhammad Ali was born in Kavalla, then part of the Turkish-based Ottoman Empire and now in Greece. In 1801, he helped evict French invaders from Egypt as an officer in the Ottoman army. The Ottoman *sultan* (prince) named him governor of Egypt in 1805. In 1831, Muhammad Ali turned against the sultan and attacked Ottoman forces, gaining temporary control of an area that now includes Syria. In 1841, the Ottoman Empire granted him and his family the hereditary right to rule Egypt. His descendants held this right until 1953, though they usually ruled under British control. Justin McCarthy

Muhlenberg, *MYOO luhn burg,* **Henry Melchior** (1711-1787), was a key figure in organizing Lutheran churches in America. Muhlenberg was born on Sept. 6, 1711, in Einbeck, Germany. In 1741, he responded to a request from Lutherans in the Philadelphia area for a pastor. When he arrived from Germany in 1742, he found the Lutheran movement disorganized and weak. Muhlenberg worked to teach Lutheran beliefs and build a strong, stable, religious identity among Lutheran colonists. He was the leader of the Pennsylvania Ministerium, which oversaw Lutheran expansion throughout the colonies and provided missionary pastors for new churches until the late 1700's.

Muhlenberg's oldest son, John, a Lutheran minister, served in the United States Congress (see **Muhlenberg,**

John Peter Gabriel). His second son, Frederick Augustus Conrad, also a Lutheran minister, served as the first Speaker of the U.S. House of Representatives from 1789 to 1791 and also from 1793 to 1795. Frederick's grandson William, an Episcopal clergyman, founded Flushing Institute, one of the first church-sponsored U.S. schools, which opened in 1828. Charles H. Lippy

Muhlenberg, *MYOO luhn burg,* **John Peter Gabriel** (1746-1807), a Lutheran minister, became a colonial military leader during the Revolutionary War in America (1775-1783). He later was elected to the United States Congress.

Muhlenberg served at churches in New Jersey from 1760 to 1771 and then became a minister in Woodstock, Virginia. There, after a Sunday service in 1776, Muhlenberg removed his robe to reveal a military uniform. He enrolled men in his parish into a regiment and became its colonel. He commanded troops at the battles of Brandywine and Germantown in Pennsylvania; Monmouth, New Jersey; and Yorktown, Virginia, and rose to the rank of major general. Pennsylvania elected him to three terms in the U.S. House of Representatives—1789 to 1791, 1793 to 1795, and 1799 to 1801.

Muhlenberg was born on Oct. 1, 1746, in Trappe, Pennsylvania. A statue of him represents Pennsylvania in the U.S. Capitol. His father, Henry M. Muhlenberg, helped found the Lutheran Church in America.

Henry Warner Bowden

Muir, *myoor,* **John** (1838-1914), an explorer, naturalist, and writer, campaigned for the conservation of land, water, and forests in the United States. His efforts influenced Congress to pass the Yosemite National Park Bill in 1890, establishing both Yosemite and Sequoia national parks. Muir helped persuade President Theodore Roosevelt to set aside 148 million acres (59,900,000 hectares) of forest reserves. A redwood forest near San Francisco was named Muir Woods in 1908 in his honor.

Muir tramped through many regions of the United States, Europe, Asia, Africa, and the Arctic. He spent six years in the area of Yosemite Valley and was the first person to explain the valley's glacial origin. In 1879, Muir discovered a glacier in Alaska that now bears his name. He called California "the grand side of the mountain" and owned a large fruit ranch there. In 1892, he founded the Sierra Club, which became a leading conservation organization (see **Sierra Club**). Muir wrote a number of books, including *The Mountains of California* (1894), *Our National Parks* (1901), and *The Yosemite* (1912).

Muir was born on April 21, 1838, in Dunbar, Scotland. His family moved to Wisconsin when he was 11. He grew up on a farm and developed a great love of nature. As a boy, he attracted attention with his inventions. He entered the University of Wisconsin at the age of 22. Muir supported himself by teaching and by doing farm work during the summer. His interests included botany and geology. Stephen Fox

Muir Woods National Monument, *myoor,* near San Francisco, has one of California's most famous redwood groves. William Kent, a California statesman, donated Muir Woods to the United States. It was established in 1908. For the area of the Muir Woods National Monument, see **National Park System** (table: National monuments). Critically reviewed by the National Park Service

Richard Frear, National Park Service

Muir Woods National Monument features a grove of towering redwood trees. The monument is located in a coastal valley just north of San Francisco.

Mujibur Rahman, *MOO jee bur RAH mahn* (1920-1975), became the first prime minister of Bangladesh in 1972. In January 1975, Mujibur Rahman (known as Mujib) took office as president of Bangladesh. Military leaders of the country overthrew Mujib's government and killed him in August 1975.

Mujib's rise to national leadership followed 25 years of political activity in East Pakistan (now Bangladesh). During that period, he was held as a political prisoner for a total of more than 10 years.

In 1970, Mujib became the unrivaled leader of the East Pakistanis. That year, the Awami League, the party headed by Mujib, won a majority of the seats in an assembly that was to write a new constitution for Pakistan. Mujib met with the West Pakistani leaders to discuss the proposed constitution. But the talks broke down, and civil war erupted between East and West Pakistan. The government imprisoned Mujib in West Pakistan. He was released after Bangladesh gained independence in December 1971. He returned home to a hero's welcome and to the tasks of building and leading a new nation.

Mujib was born on March 17, 1920, in Tungipara, 60 miles (97 kilometers) southwest of Dhaka. He graduated from Islamia College in Calcutta (now Kolkata) and studied law for a short time at Dhaka University. In 1996, Mujib's daughter Sheikh Hasina Wajed became prime minister of Bangladesh. Stanley J. Heginbotham

Mukden. See **Shenyang.**

Mulatto, *muh LAHT oh,* is a person of mixed white and black descent. The term *mulatto* also applies to those who have one white and one black parent. The child of a white person and a mulatto is a *quadroon.* Some mulattoes have dark skins and kinky hair, and some do not. The word *creole* is often confused with *mulatto.* In the United States, a creole is a white Southerner of French or Spanish ancestry. See also **Creole; Latin America** (People; picture); **Mestizo.** Douglas H. Ubelaker

Mulberry is any of a group of ornamental trees and shrubs that have small, round, sweet fruits. The fruits, also called mulberries, are white, purple, or red. Each consists of a cluster of tiny one-seeded fruits. Mulberry flowers are greenish white and grow in cylindrical clusters that hang from stalks on the branches. The plants have oval or heart-shaped ridged leaves.

White mulberries play an important role in the silk industry. Their leaves provide food for silkworms, from whose cocoons silk fabrics are woven. The chief kind of white mulberry used as silkworm food is the silkworm mulberry. Most silkworm mulberries come from China. Russian mulberries, another important type of white mulberries, are the most widely planted mulberries in the United States. They are sturdy shrubs that grow well as hedges, and so growers use them as windbreaks.

© Eric & David Hosking

The black mulberry tree bears crimson-black fruit. This tree is grown throughout Europe, where its juicy fruit is eaten fresh and is used to make preserves and wines.

Red mulberries, also called American mulberries, grow wild throughout most of the eastern and central sections of the United States. Farmers feed their fruit to hogs and poultry. Black mulberries are grown throughout Europe for their juicy, crimson-black fruit. The fruit is eaten fresh and used in making preserves and wines.

Max E. Austin

Scientific classification. Mulberries belong to the mulberry family, Moraceae. White mulberries are *Morus alba.* Silk mulberries are *M. alba,* var. *multicaulis.* Russian mulberries are *M. alba,* var. *tatarica.* Red mulberries are *M. rubra,* and black mulberries are *M. nigra.*

See also Silk; Tree (Familiar broadleaf and needleleaf trees [picture]).

Mulch is any material that is spread over soil so that air can get through, but less water can evaporate from the soil. Mulch may be made of manure, straw, hay, clover, chaff, alfalfa, corncobs, leaves, sawdust, wood chips, and many other substances. It is often applied about 2 to 3 inches (5 to 8 centimeters) thick. It helps keep water in the soil by reducing evaporation, and it also decays and enriches the soil. It also reduces the number of weeds that would otherwise grow up to compete with plant crops. Mulch is valuable to home gardeners, but it often costs more than commercial fertilizers. Taylor J. Johnston

Muldoon, Sir Robert (1921-1992), served as prime minister of New Zealand from 1975 to 1984. He became the leader of the National Party in 1974. Muldoon took office as prime minister after leading his party to victory over the Labour Party in the 1975 election. His party won again in 1978 and 1981, and Muldoon remained as prime minister. But the Labour Party defeated Muldoon's party in 1984, ending Muldoon's term.

Muldoon was born on Sept. 25, 1921, in Auckland, New Zealand. He served in the army during World War II (1939-1945) and studied cost accounting in England after the war. He became an expert accountant and a partner in an Auckland accounting firm. Muldoon first won election to Parliament in 1960. He served as minister of finance from 1967 to 1972 and as deputy prime minister in 1972. Muldoon was knighted in 1984. Andrew Stone

Mule is a domesticated, hybrid animal that results from crossing a *mare* (female horse) and a *jack* (male donkey). The offspring of a male horse (stallion) and a female donkey (jenny) is called a *hinny.* Other mulelike hybrids were bred during ancient times from horses and onagers. Mules were once popular work animals throughout the world. Some breeders even raised certain types of large donkeys in order to produce sizeable mules.

A mule resembles both its parents. Like the jack, a mule has long ears, short mane, small feet, and a tail with a tuft of long hairs at the end. From the mother it gets a large, well-shaped body and strong muscles. She also gives it a horse's ease in getting used to harness. The father gives the mule a braying voice, sure-footedness, and stamina. Like the jack, a mule saves its strength when forced to work hard and for a long time. A mule is less likely to suffer from overwork than a horse.

Mules are hardy and resist disease well. Unfortunately, mules do not have offspring of their own, except in rare cases. Animals which cannot have offspring are said

Grant Heilman

The mule has long ears, a short mane, and a tail tipped with long hairs. It is the offspring of a male donkey and a female horse. Mules usually cannot have offspring of their own.

Garry D. McMichael, Photo Researchers

A mule can be used to pull a plow and do other hard work on farms and plantations. Mules are sure-footed and have strong muscles. They have been used as work animals throughout the world.

to be sterile. All male mules and most female mules are sterile. A few female mules have produced young after they were bred to male asses or to stallions.

Mules can remain strong under much harsh treatment and work, but they work better if they are treated with kindness. When owners take proper care of their mules, the mules will do as much work as horses, and they will do the work under more harsh conditions. The hardiness of mules makes them suitable for work in construction camps, mines, and military zones.

In the United States, over nine-tenths of all the mules have worked on farms and plantations. Most of them have been used in the South. Geo. H. Waring

Mule deer is a beautiful deer that has large, furry ears similar to those of a mule. This grayish- to brownish-colored deer stands about 3 to 3 $\frac{1}{2}$ feet (91 to 107 centimeters) high, and has large, branching antlers. It has a peculiar stiff-legged gait that enables it to swiftly bound over the roughest trails. Mule deer live from northern Mexico north to the southern parts of Alaska and Canada's Yukon Territory, and from northern Texas and eastern North Dakota west to the Pacific Coast. In the Pacific Northwest, mule deer are called *black-tailed deer.*

Mule deer eat a wide range of vegetation, including grasses and the buds, leaves, and twigs of shrubs and small trees. They may eat farm crops. Mule deer are normally active only around dawn and dusk. They may live in herds of 5 to 20 animals, spending summer in hills and mountains and winter in valleys. Gregory K. Snyder

Scientific classification. Mule deer are members of the deer family, Cervidae. Their scientific name is *Odocoileus hemionus.*

Ray Richardson, Animals Animals

Mule deer have large, furry ears that look somewhat like those of a mule. In this photograph, a buck, *right,* guards a doe during mating season. Mule deer live in western North America.

Mullein, *MUHL uhn,* also called *mullen,* is the name of a group of plants native to Europe and Asia. There are more than 250 kinds of mulleins. Three kinds grow in the United States and southern Canada. The *common mullein* is found in rocky pastures, along roadsides, and in waste places. It grows to 6 feet (1.8 meters) high and has a thick, woolly stem and thick, velvety leaves. Yellow flowers grow in clusters in the form of a spike at the top of the stalk. The smaller *moth mullein* has smooth, deeply

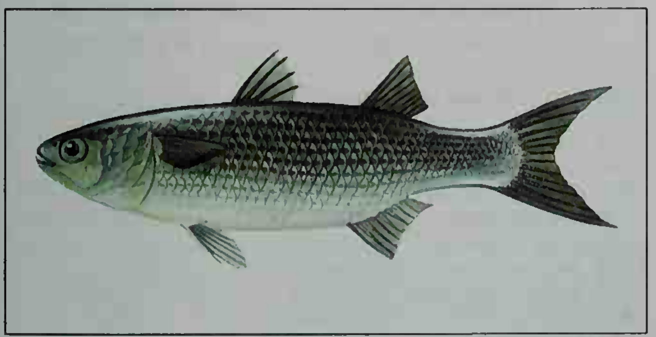
WORLD BOOK illustration by Robert Hynes

Common mullein

veined leaves. Both the stem and leaves of these plants irritate the skin when touched. The *white mullein* grows in the eastern United States. A thin, powdery down covers this plant.

The leaves of the common mullein were formerly used to make a tea for treating coughs, nervous disorders, and inflammations. Certain mulleins often grow as weeds. They may be controlled by cutting the flower stalks before the seed forms or by spraying with a *herbicide* (chemical weedkiller). Kenneth A. Nicely

Scientific classification. Mulleins belong to the figwort family, Scrophulariaceae. The scientific name for the common mullein is *Verbascum thapsus.* The moth mullein is *V. blattaria.* The white mullein is *V. lychnitis.*



Mullens, Priscilla. See Alden, John and Priscilla.

Muller, Marcia (1944-), is a popular and influential American writer of detective fiction. She created private detective Sharon McCone, introducing the character in the novel *Edwin of the Iron Shoes* (1977). McCone is considered the first modern realistic American female private detective in book form. Her success influenced such American detective writers as Sue Grafton and Sara Paretsky. Both created popular women detectives who reflected McCone's toughness and independence.

Critics and readers have praised Muller for her vivid descriptions of northern California and for the realism of the supporting characters in her novels. Her detective, Sharon McCone, works in the San Francisco area. McCone is particularly committed to investigating the causes of a crime and how a criminal thinks. She is unmarried, but often falls in and out of love in the earlier novels. In the later novels, she forms a permanent romantic relationship with private investigator Hy Ripinski.

Muller was born on Sept. 28, 1944, in Detroit and began writing detective fiction after receiving B.A. (1966) and M.A. (1971) degrees from the University of Michigan. Muller has also created two other female detectives, Joanna Stark, a partner in a California art security firm, and Elena Oliverez, a California museum curator. Muller is married to mystery writer Bill Pronzini. They have coedited many collections of crime and suspense stories. Jon L. Breen

Mullet, *MUHL iht,* is the name of two different families of silvery-blue fish with stout bodies. Mullets are from 1 to 2 feet (30 to 60 centimeters) long and have blunt heads and small mouths. The teeth, if any, are very weak. Great numbers of these fish live close to the shore in nearly all temperate and tropical waters. Their flesh is wholesome and has a good flavor.

WORLD BOOK illustration by Colin Newman, Linden Artists Ltd.

A mullet has a stout, silvery-blue body. Mullets are plentiful in coastal waters in most warm regions of the world. The flesh of these fish has a good flavor.

The *striped mullet* is the largest of all the species, weighing from 10 to 12 pounds (4.5 to 5.4 kilograms). Striped mullets are plentiful around the Florida Keys and on the Gulf Coast. The *liza* and the *white mullet* live in the same areas as the striped mullet and are about as large.

Surmullets, or *red mullets,* are small, brightly colored fish that live chiefly in warm seas. They have small mouths and weak teeth. Two long feelers called *barbels* hang like strings from the chin of the red mullet.

William J. Richards

Scientific classification. Mullets make up the mullet family, Mugilidae. The striped mullet is *Mugil cephalus.* The liza is *M. liza,* and the white mullet is *M. curema.* Red mullets belong to the goatfish family, Mullidae.

Mulligan, Gerry (1927-1996), was perhaps the most important baritone saxophonist in jazz during the middle and late 1900's. In 1949 and 1950, he participated in a series of recordings that shaped the cool jazz style of the 1950's. In 1952, he formed a revolutionary quartet with trumpeter Chet Baker that omitted a piano, which had previously been an essential rhythm instrument in jazz groups. Mulligan's later pianoless quartets featured trombonist Bob Brookmeyer and trumpeter Art Farmer. Mulligan recorded with such soloists as Paul Desmond, Stan Getz, Johnny Hodges, Thelonius Monk, Dave Brubeck, and Ben Webster. His compositions include "Godchild," "Soft Shoe," "Venus de Milo," and "Walkin' Shoes."

Gerald Joseph Mulligan was born on April 6, 1927, in New York City. He left school at the age of 17 to begin a career as an arranger and musician. He first earned national recognition in 1947 when he composed and arranged "Disc Jockey Jump" for the Gene Krupa band. He also did arrangements for the bands of several famous leaders, including Stan Kenton, Miles Davis, and Claude Thornhill in the late 1940's and early 1950's. Mulligan was an important member of the famous Miles Davis recordings of 1949 and 1950 called "Birth of the Cool." During the early 1960's, Mulligan led a popular big band that, like his quartet, had no pianist. Frank Tirro

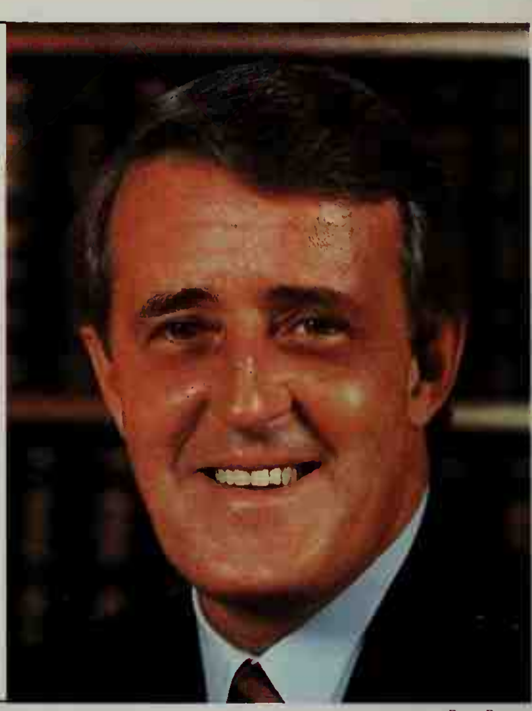
See also **Jazz** (Cool jazz).

Mulliken, Robert Sanderson (1896-1986), an American chemist, won the 1966 Nobel Prize in chemistry. He received the award for his *molecular-orbital theory,* which he adopted in 1925. This theory describes the arrangement of electrons in molecules.

The electrons of an atom orbit its nucleus. Scientists once believed that the electrons continued to orbit the individual atomic nuclei after atoms had combined to form a molecule. But Mulliken showed that each atom's outermost electrons can orbit the entire molecule. Most scientists accept this theory.

The molecular-orbital theory has been applied in such fields as biological and industrial research. For example, scientists have used the theory to study the structure of proteins, plastics, and a number of other complex compounds.

Mulliken was born on June 7, 1896, in Newburyport, Massachusetts. He graduated from the Massachusetts Institute of Technology in 1917 and received a Ph.D. degree from the University of Chicago in 1921. He taught at the university from 1928 to 1961. Daniel J. Kevles



Brian Mulroney

Prime Minister of Canada
1984-1993

Turner
1984

Mulroney
1984-1993

Campbell
1993

Peter Bregg

Mulroney, *muhl ROO nee,* **Brian** (1939-), served as prime minister of Canada from 1984 to 1993. Mulroney had been chosen leader of the Progressive Conservative Party in 1983. Before 1983, Mulroney had been a lawyer and business executive and had never been elected to a public office. But he led the Conservatives to a landslide victory in the election of 1984 and succeeded John N. Turner as prime minister. Mulroney remained in office after the general election of 1988. In 1993, he resigned as prime minister and leader of the Progressive Conservative Party. He was succeeded by Kim Campbell, the minister of national defence.

During college and law school in the late 1950's and early 1960's, Mulroney had held many leadership positions in Progressive Conservative student groups. After graduating, he practiced law and served on party committees. In 1977, Mulroney became president of the Iron Ore Company of Canada. He held that position until he became Progressive Conservative Party leader.

Mulroney's friends knew him to be charming and persuasive. Associates rated him as an able negotiator who at times was tough and cautious.

As prime minister, Mulroney faced the challenges of keeping the province of Quebec a part of Canada and of leading the country through an economic recession. His efforts to amend the Canadian Constitution to satisfy Quebec separatists failed. His economic proposals, including the introduction of a new federal sales tax, lost him popularity. However, Mulroney achieved a major goal in 1988 when he signed a free-trade agreement with the United States. In 1992, he signed a pact that extended the agreement to include Mexico.

Early life

Boyhood. Mulroney was born on March 20, 1939, in Baie-Comeau, Que. His full name is Martin Brian Mulroney, but he prefers to be called Brian Mulroney. He was the third oldest of the six children of Benedict M. Mulroney and Irene O'Shea Mulroney. Brian's father was an electrician for a paper company in Baie-Comeau.

Brian became an excellent tennis player as a teenager and won the Baie-Comeau Junior Tennis Championship. He attended local schools until he was 13 years old. Then his parents sent him to St. Thomas College, a boys' school in Chatham, N.B.

College education. In 1955, at the age of 16, Mulroney entered St. Francis Xavier University in Antigonish, N.S. He earned honors in political science and developed an interest in politics. Mulroney's parents had supported the Liberal Party. But Brian came to admire Robert L. Stanfield, leader of the Nova Scotia Progressive Conservative Party, and joined the Conservative club at the university. He was elected president of the club in 1958. In 1959, he received a B.A. degree.

Mulroney then enrolled at Dalhousie University in Halifax, N.S., to study law. Later in 1959, he was elected executive vice president of the Progressive Conservative Student Federation of Canada. In 1960, he transferred to Laval University Law School in Ste.-Foy, Que. In 1961, he became leader of the Progressive Conservative club at Laval. Mulroney received his law degree in 1963.

Early business career

Young lawyer. After graduating from law school, Mulroney joined the Montreal law firm of Ogilvy, Re-

Important dates in Mulroney's life

1939 (March 20) Born in Baie-Comeau, Que.
1959 Graduated from St. Francis Xavier University.
1959 Elected executive vice president of Progressive Conservative Student Federation.
1973 (May 26) Married Mila Pivnicki.
1974 Became member of Cliche Royal Commission.
1977 Became president of Iron Ore Company of Canada.
1983 Elected leader of Progressive Conservative Party.
1984 (Sept. 17) Became prime minister of Canada.
1988 Led Conservatives to victory again.
1993 (June 25) Resigned as prime minister and leader of the Progressive Conservative Party.

nault. He specialized in labor law. His involvement with the Progressive Conservative Party continued to grow. He served on its policy committee from 1966 to 1971 and on the finance committee of the Quebec Progressive Conservative Party from 1966 to 1974.

On May 26, 1973, Mulroney married Mila Pivnicki (1953-) of Montreal. The Mulroneys had four children, Caroline (1974-), Benedict (1976-), Robert Mark (1979-), and Daniel (1985-).

In May 1974, Mulroney was appointed to the Cliche Royal Commission, which was established to investigate violence in Quebec's construction industry. He frequently appeared on the evening television news and began to gain national prominence.

First bid for leadership. In 1975, Progressive Conservative leader Robert L. Stanfield announced his intention to retire. Mulroney's work on the Cliche commission had impressed influential members of the Progressive Conservative Party, and they urged him to become a candidate for the leadership. Mulroney accepted the challenge and ran a strong campaign. The party met to choose its new leader in February 1976. Mulroney finished third in the voting.

Business executive. In June 1976, Mulroney joined the Iron Ore Company of Canada as executive vice president of corporate affairs. He had done some legal work for the Quebec-based company and was chosen for his new job by the company's president, William Bennett. In 1977, Bennett retired, and Mulroney succeeded him as president. The firm had long been troubled by labor strikes and was deeply in debt. Mulroney settled the labor disputes and led the company to record profits.

During the early 1980's, decreased demands for steel led to a sharp drop in iron ore prices. Iron ore is used to make steel, and the Iron Ore Company suffered large losses. As a result, the company closed its mine in Schefferville, Que., in 1982. Mulroney arranged a compensation and relocation program for the 285 employees who lost their jobs.

Career in government

Election as party leader. Joe Clark of Alberta had led the Progressive Conservative Party to power in the general election of 1979. But the Liberals regained control in a general election the next year. Opposition to Clark's leadership then began to grow.

Early in 1983, Clark resigned and called a party convention for June to select a new leader. Mulroney became a major candidate for the leadership even though he had never won election to a public office. His supporters felt that his Quebec connections would help strengthen the party's prospects in that province, a traditional stronghold of the Liberal Party. Quebec had about a fourth of Canada's population.

Clark tried to regain his position at the convention, but Mulroney's fresh appeal and Quebec background helped carry him to victory. Mulroney was the first Progressive Conservative leader ever to win that position without any experience in an elected office. Two months later, he easily won election to the Canadian House of Commons from a district in Nova Scotia.

The 1984 election. Prime Minister Pierre Trudeau retired in 1984. He was succeeded in late June 1984 by John N. Turner, a Toronto lawyer who had held several Cabinet positions in the governments headed by Lester B. Pearson and Trudeau. Turner called a general election for Sept. 4, 1984.

At the time of the campaign, Canada's economy was slowly recovering from a recession. The unemployment rate was still high, standing at 11 percent of the labor force. Mulroney promised that a new Conservative government would create jobs and increase industrial productivity and foreign investment. In the election, he led the Progressive Conservative Party to a huge victory. The party won 211 of the 282 seats in the House of Commons. It captured 58 of Quebec's 75 seats, the most the Conservatives had ever won there. Mulroney took office as prime minister on September 17.

Prime minister. Mulroney faced many problems during the early part of his term. The economy grew only slightly, unemployment remained high, and the federal budget deficit rose sharply. Mistakes and blunders by the Cabinet also hurt Mulroney's image. By May 1986, five ministers had resigned under severe public criticism. The next month, Mulroney moved half his ministers into new jobs. He also retired two, fired four, and added eight other ministers.

The Meech Lake accord. In 1987, Mulroney helped bring about an agreement that was partly designed to win Quebec's acceptance of the Canadian Constitution. Quebec had earlier refused to accept the Constitution because the document did not recognize the province as a distinct society in Canada. On June 3, 1987, Mulroney and Canada's 10 provincial heads of government signed a constitutional agreement that proposed such recognition. The agreement, called the Meech Lake accord, also included other constitutional changes and was sent to the provincial legislatures for ratification. However, the accord was never ratified.

Many opponents of the Meech Lake accord believed that it would have granted Quebec's provincial government too much power over the rights of individuals in Quebec—especially over the rights of Quebec's English-speaking minority. Most people in Quebec speak French. Eight of the 10 provinces ratified the accord, but Manitoba and Newfoundland withheld their support. As a result, many Quebecers began to demand increased independence for Quebec from the rest of Canada.

Free trade and the 1988 election. On Jan. 2, 1988, Mulroney and United States President Ronald Reagan signed a major trade pact between Canada and the United States. The agreement called for the elimination of all tariffs and many other trade barriers by 1999. However, the Liberal Party opposed the agreement and blocked its ratification in the Canadian Senate.

John N. Turner, the Liberal Party leader, demanded that Mulroney call a general election to let Canadians express their approval or disapproval of the agreement. The Liberal senators promised to ratify the pact if the Progressive Conservatives won the election.

Mulroney called a general election for Nov. 21, 1988. The Progressive Conservatives won a majority of the seats in the House of Commons, and Mulroney continued as prime minister. After the general election, the Canadian Senate approved the free-trade agreement, and the pact went into effect on Jan. 1, 1989.

Other economic developments. In April 1989, the Mulroney government proposed a federal budget de-

Andrew Clark, Office of the Prime Minister

The Mulroney family. Standing are son Benedict, *left,* and daughter Caroline, *right.* Seated are son Robert Mark, Mulroney, son Daniel Nicholas Dimitri, and Mulroney's wife, Mila.

signed to reduce Canada's large budget deficit. The new budget called for tax increases and spending cuts.

To help raise revenue, Mulroney's government proposed a controversial new federal sales tax. The tax, called the *goods and services tax* (GST), applied to almost all goods and services sold in Canada. It replaced a tax that had covered fewer purchases. Most Canadians opposed the new tax, but it went into effect in 1991.

In April 1990, Canada was struck by a recession that ended seven years of economic growth. By March 1991, 10.5 percent of Canadian workers were unemployed. Mulroney's government was criticized for not doing enough to end the recession. By mid-1991, support for Mulroney dropped sharply.

In 1992, Mulroney signed the North American Free Trade Agreement (NAFTA) between Canada, the United States, and Mexico. This pact built on the Canada-United States free-trade agreement by calling for the gradual elimination of tariffs and certain other trade barriers between those two countries and Mexico. NAFTA took effect in 1994.

The Persian Gulf War. In 1991, the Mulroney government authorized the participation of the Canadian Armed Forces in the Persian Gulf War. Canadian pilots flew bombing missions over Iraq and Kuwait from their station in Qatar, a country near Saudi Arabia.

The constitutional crisis. After the failure of the Meech Lake accord, Quebec's ruling Liberal Party adopted a platform demanding sole authority in the province over such matters as agriculture, energy, and trade. It also demanded a role in forming Canada's foreign policy. It announced that it would ask Quebecers to vote on the separation of Quebec from the rest of Canada if the Canadian government did not agree to its demands by the fall of 1992. Mulroney supported more independence for Quebec but strongly opposed separation. In 1991, he appointed former prime minister Joe Clark minister for constitutional affairs. In this post, Clark worked to preserve Canada's national unity.

In September 1991, Mulroney introduced a new plan to revise the Constitution. The plan provided for recognition of Quebec as a distinct society, the replacement of Canada's appointed Senate with an elected one, and self-government for Canada's native peoples. It also proposed the transfer of some federal powers to the provinces. A parliamentary committee soon met to discuss and gather public opinion on the plan.

In August 1992, Clark and 10 provincial heads of government agreed to a set of constitutional amendments based on Mulroney's plan. The agreement became known as the Charlottetown accord. To go into effect, the amendments required ratification by the provinces. In addition, Mulroney called for a nationwide vote on the amendments. The vote was held in October, and most Canadians, including majorities in Quebec and each of five other provinces, voted against the accord.

In February 1993, Mulroney announced his resignation as prime minister and leader of the Progressive Conservative Party. He said he had lost enthusiasm for governing. He called a party convention to be held in June to choose his replacement. Defence Minister Kim Campbell won the party leadership, and she was sworn in as prime minister on June 25. Mulroney returned to private life and the practice of law. Kendal Windeyer

Multiculturalism is a political or social philosophy that promotes cultural diversity. It is supported by many educators in the United States. These educators favor the teaching of different cultures for the purpose of understanding and appreciating them. Such teaching is called *multicultural education.*

Supporters of multicultural education claim U.S. schools have paid too little attention to the contributions of women, non-Europeans, and people of Hispanic ancestry. These supporters feel that social conflict would be reduced in the United States if Americans were better able to understand and appreciate the nation's diverse cultures and peoples. They also feel it is important that Americans recognize the injustices that have sometimes been suffered by women, African Americans, Hispanics, and other groups in American society. In addition, the supporters claim that members of these groups derive valuable pride and self-esteem from seeing their cultures being taught in the schools.

Some critics believe that supporters of multicultural education undervalue America's traditional heritage, which is largely based on European culture. They argue that American law and political institutions are an important part of this heritage, and that the heritage is therefore the reason America welcomes so many diverse peoples. These critics stress that schools should teach *cultural literacy*—that is, the values and content of America's traditional heritage.

Multiculturalism grew out of a reaction against the idea of the *melting pot,* a traditional way of understand-

ing America's identity. According to this idea, U.S. society was like a boiling pot into which all immigrants were thrown. As immigrants "melted" into the mix, they lost their previous cultural or ethnic identities and became "true" Americans. The melting pot idea became popular in the late 1800's and early 1900's. And many immigrants or their descendants did adopt a general American culture. But some people began to challenge the melting pot idea in the 1950's and 1960's. By the 1970's, some began to prefer the image of a *salad bowl* instead. In the salad bowl model, different cultural or ethnic groups were thought of as being "tossed" together in such a way that each kept its unique identity. Numerous multiculturalists have preferred the salad bowl concept, and many members of minority groups have worked to preserve the distinct culture of their group. Stephen M. Fain

Multimedia, *MUHL tih MEE dee uh,* is a computer-controlled combination of text, graphics, sound, photographs, motion pictures, and other types of media. Multimedia programs have a variety of applications in education, entertainment, job training, sales presentations, and other areas.

The hardware needed to run multimedia programs usually includes a personal computer with a large-capacity memory and high-quality video and audio systems. Many multimedia programs require a *CD-ROM* or *DVD-ROM* drive. Such programs are stored on disks that resemble audio compact discs. CD-ROM's can store a huge amount of data, and DVD-ROM's can store even more. A computer with a device called a *modem* may be used to run multimedia programs available on the Internet, the worldwide network of computers. Some computer systems enable users to record video and audio on a computer's hard disk drive or on a recordable CD-ROM to create their own multimedia programs.

Computer users *interact* with multimedia programs—that is, they become active participants rather than passive observers. For example, a multimedia program could employ an interactive story to improve a user's Italian language skills. The story might involve a search for an apartment in Rome. The program could begin with a motion-picture clip showing a couple walking past several apartment buildings. The user would select a building and listen to the conversation between the landlord and the couple. At the end of the conversation, the user could decide to continue searching or to choose an apartment in that building. At any point during the story, the user could access the program's dictionary or request a translation of the dialogue.

Many computer programs combine several types of media, such as text, graphics, animation, and sound. But most do not offer television and movie clips or digital stereo sound. Such high-quality video and audio distinguish multimedia from other programs. Keith Ferrell

Multinational corporation is a business organization that is based in one country and has branches, subsidiaries, and plants in many countries. Such organizations carry out substantial amounts of financing, production, sales, and research and development in their foreign operations.

Multinational corporations, also called *MNC's* and *transnational corporations,* have developed since World War II ended in 1945. MNC's can have great economic power. The largest MNC's include Exxon Mobil Corporation, Ford, General Motors, and Royal Dutch/Shell, each of which has reported annual sales of greater than $75 billion. This figure is larger than the gross national products of more than 80 percent of the world's countries.

The main reasons firms develop into MNC's are (1) to obtain control over the supply of resources, (2) to take advantage of the lower costs of foreign labor and materials, (3) to avoid paying tariffs on imported goods, and (4) to avoid high production costs and taxes associated with certain operations in the home country.

Operation. Most multinational corporations are based on manufacturing or minerals industries. They operate in fields that involve frequent technological change, including the production of computers, drugs, and electronic equipment. A typical firm in such fields has a large research organization in the country in which it has its headquarters. There, the firm develops new products and manufacturing processes. It then trains workers in its foreign plants to use these new skills. Some multinational corporations grant foreign companies a license to use their methods and processes instead of setting up plants of their own.

A multinational firm may have a few plants in one country that produce complete products to be sold in several countries. In other cases, plants in many countries may each make parts of the finished products. This process gives the MNC a larger area from which to choose the most economical locations for specialized plants. The corporation can then sell its products at lower prices than would otherwise be possible.

Debate over MNC's. The economic role of multinational corporations has aroused widespread international debate. In the United States, for example, some labor groups believe that U.S. MNC's have increased unemployment at home by establishing operations in other countries. However, some studies have indicated that MNC's have preserved or created more jobs for U.S. citizens than they have eliminated. Another concern is that, by shifting production operations overseas, U.S. MNC's decrease the flow of funds earned by U.S. exports. However, MNC defenders argue that such actions by U.S. MNC's are offset by foreign-based MNC's locating production operations within the United States.

Abroad, many people oppose U.S. multinational corporations because of their control over local economies and the profits they earn. But supporters of MNC's emphasize the contributions of an MNC's technology and capital to economic development. Robert B. Carson

Multiple birth is the birth of more than one infant from the same pregnancy. Twins, triplets, quadruplets, and quintuplets are all examples of multiple birth. Most animals give birth to more than one offspring at a time. Human beings usually have only one baby at a time. This article discusses multiple births in human beings.

Kinds of multiple births. Most multiple births in humans involve twins. Twins occur about once in every 89 births. By contrast, triplets occur about once in every 7,900 births, and quadruplets occur about once in 705,000 births. The two most commonly recognized types of twins are *fraternal* and *identical.* Fraternal twins may be of the same sex or consist of a brother and a

Gerard Smith, Monkmeyer

Nancy Hays, Monkmeyer

Twins, the most common human multiple birth, occur about once in 89 births. Identical twins often look much alike, *top*. Fraternal twins may resemble each other only slightly, *above*.

sister, with each individual having a different genetic makeup. Identical twins are always of the same sex and have an identical genetic makeup. They generally are more difficult to tell apart physically than are fraternal twins.

Researchers have found that the rate at which identical twins occur—about 4 times in every 1,000 births—is fairly constant. But the birth rate of fraternal twins is highly variable. Fraternal twins occur more frequently among black people, particularly black Africans, than among people of European ancestry, including white Americans. Fraternal twins are least common among Asians. Scientists do not know why such variations exist.

How multiple births occur. In pregnancies that produce a single infant, one of the mother's ovaries releases an egg that joins with a sperm from the father. The fertilized egg, called a *zygote,* develops into a baby.

In multiple births, the process of development is somewhat different. For example, in pregnancies involving fraternal twins, also called *dizygotic twins,* the mother's ovaries release two eggs at about the same time. Each egg is fertilized by a separate sperm, producing two zygotes, each with different genetic characteristics. As a result, fraternal twins may look no more alike than brothers or sisters who are not twins. Identical twins, also called *monozygotic twins,* originate from a single zygote. Early during the mother's pregnancy, the zygote's cell mass divides into two parts. The two parts develop into separate individuals who have the same genetic makeup. Scientists believe that *conjoined twins,* formerly called *Siamese twins,* develop from a zygote that fails to separate completely (see **Conjoined twins**).

Multiple births involving three or more infants occur through processes that are similar to those involving the development of twins. For example, if the mother's ovaries release three, four, or five eggs and each of the eggs becomes fertilized, fraternal triplets, quadruplets, or quintuplets will be born. A zygote that divides into more than two parts will result in the birth of identical triplets, quadruplets, or quintuplets. If two eggs are fertilized and one of the eggs splits in two, the mother will give birth to triplets consisting of identical twins and one nonidentical baby.

Fertility drugs may raise the chances of a multiple birth. In women, these drugs stimulate production of eggs, and several eggs may be released at the same time. Fertility drugs may be used alone or as preparation for a procedure called *in vitro fertilization.* In this procedure, several mature eggs are removed from a woman's ovaries and combined with sperm in a laboratory dish. The doctor then places several successfully fertilized eggs directly into the woman's uterus or fallopian tubes. Inserting several eggs increases the likelihood of a successful pregnancy, but also increases the chance of a multiple birth. Melvin V. Gerbie

Multiple sclerosis, *sklih ROH sihs,* often called MS, is a disease of the nervous system. It is characterized by repeated attacks of nervous system damage, followed by recovery. The time and severity of attacks are unpredictable. The illness can cause serious disabilities, including paralysis of the legs and partial loss of vision. MS afflicts more women than men. Most patients begin to have symptoms of MS when they are from 20 to 25 years old. MS is the most common cause of disability for people under the age of 45 in the United States.

MS is characterized by scattered areas of inflammation and by destruction of *myelin* in the white matter of the brain and spinal cord. Myelin is a fatty substance that surrounds and protects certain nerve fibers. Many small, hard, platelike areas of scar called *plaques* appear throughout the myelin and interfere with the normal function of nerve pathways. The word *sclerosis* comes from a Greek term that means *hard* and refers to the plaques. Some studies suggest that MS may kill nerve cells in addition to damaging myelin.

The symptoms of MS depend on which areas of the brain and spinal cord are affected. Therefore, the symptoms differ with each attack. In time, more and more plaques develop in the victim's myelin, causing new symptoms. Physicians diagnose MS chiefly from the symptoms. A technique called *magnetic resonance imaging* (MRI) can aid in diagnosis. MRI produces highly detailed images of the brain that can rule out other diseases or reveal the telltale plaques.

The first symptoms may appear suddenly, but they may also start slowly and gradually worsen. Difficulty walking is commonly the first problem. Loss of vision, double vision, loss of balance, and weakness in an arm or leg may also occur. Numbness or tingling may occur in the fingers or elsewhere, and problems of coordination are also common. After several days to several weeks, these symptoms decrease and may disappear entirely. New attacks appear unpredictably after periods of recovery lasting months to years. In a small number of patients, symptoms are progressive with no apparent

recovery between attacks. About a third of MS patients become seriously disabled, but few die from MS.

Physicians do not know the cause of MS. Many experts think that the disease may involve malfunctions in the body's immune system. Normally, the immune system defends the body against disease by attacking bacteria, viruses, and other invaders. Immune defenses include substances called *antibodies* and white blood cells. In MS, a defect in the immune system may allow antibodies or white blood cells to attack myelin.

Certain genes that control the body's immune system are associated with MS. Many scientists think the immune system, under the control of genes, may react with an unidentified environmental factor—possibly a virus—to produce a condition that can lead to MS.

There is no cure for MS. Many patients receive drugs called *corticosteroids* as treatment for attacks. Certain other drugs, such as *interferons* and *glatiramer acetate,* can slow the progression of the disease and reduce the frequency of attacks for some patients. William J. Weiner

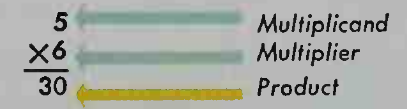
Multiplication is a short way of adding or counting equal numbers. Multiplication is one of the four basic operations in arithmetic along with addition, subtraction, and division.



Suppose you want to know how much six gumballs will cost. The gumballs are 5¢ each. You can find the answer by addition: 5+5+5+5+5+5=30. Six gumballs will cost 30¢. However, it is easier to learn that six 5's are 30. Learning facts like this is the basis of multiplication.

Learning to multiply

Many people learn multiplication only by memorizing its facts and rules. Often people do not understand the methods that they are using. The best way to learn how to multiply is to find out how multiplication works.

Writing multiplication. Operations in arithmetic are shown by symbols. The symbol for multiplication is ×. The statement 6×5=30 means "six 5's are 30." People also say, "5 multiplied by 6 is 30," or "6 times 5 is 30."

The number that is being multiplied, or added together a number of times, is called the *multiplicand.* The number that does the multiplying, or the number of multiplicands to be added, is called the *multiplier.* The result, or answer, is called the *product.* A multiplication problem is usually written like this:

You do not need to write the names, but you must keep the columns straight when multiplying larger numbers. An understanding of place value is important in multiplication. See **Decimal system** (Multiplication).

Multiplication facts. A statement such as 6×5=30 is a *multiplication fact.* It consists of a multiplier, a multiplicand, and a product. You should use addition to discover the multiplication facts. For example, 5+5+5+5+5+5=30. After discovering a multiplication fact, you should memorize it. By knowing the 100 multiplication facts, you can learn to multiply any numbers.

Most of the multiplication facts are easy to learn. If you play a game and score 0 four times, your score is 0, because 4×0=0. Zero multiplied by any number is

Multiplication terms

Annexing zeros is a quick way of multiplying by 10, 100, 1,000, and so on. It means placing zeros at the end of the number being multiplied.
Carry, in multiplication, means to change a number from one place in the product to the next. A 10 in the 1's place is carried to the 10's place.
Multiplicand is the number that is multiplied. In 4×8=32, 8 is the multiplicand.
Multiplication fact is a basic statement in multiplication, such as 6×3=18.
Multiplier is the number that does the multiplying. In 4×8=32, 4 is the multiplier.
Partial product is the result of multiplying a number by one digit of the multiplier. It is used when the multiplier has two or more digits.
Product is the answer or result of multiplication. In 4×8=32, 32 is the product.

zero. Any number multiplied by zero is also zero. You have now learned 19 of the multiplication facts!

If you make a score of 1 four times, your score is 4, because $4\times1=4$. Similarly, $5\times1=5$, $6\times1=6$, and $8\times1=8$. One multiplied by any number is that number. Any number multiplied by one is also that same number. You now know 17 more multiplication facts.

The two boxes of eggs shown below illustrate an important rule in multiplication. Each box contains 12 eggs. You can look at the box of eggs at the left in two ways. You might say that there are six rows of eggs with two eggs in each row. Or, you could say that there are two rows of eggs with six eggs in each row.

WORLD BOOK photos by Odyssey Productions

You can also look at the box of eggs at the right in two ways. You might say that there are four rows of eggs with three eggs in each row. Or, you could say that there are three rows of eggs with four eggs in each row. The multiplication facts that show this are:

$6\times2=12$ $\quad$ $4\times3=12$
$2\times6=12$ $\quad$ $3\times4=12$

The examples of the boxes of eggs illustrate that *numbers can be multiplied in any order,* which is known as the *commutative property of multiplication.* The products will always be the same. Knowing this rule cuts down the number of multiplication facts to be learned from 100 to 55.

Knowing the *squares* is helpful in learning the multiplication facts. A square is a number multiplied by itself. Here are the squares that help to learn the facts:

$2\times2=4$ $\quad$ $5\times5=25$ $\quad$ $8\times8=64$
$3\times3=9$ $\quad$ $6\times6=36$ $\quad$ $9\times9=81$
$4\times4=16$ $\quad$ $7\times7=49$

You can make pictures of the squares with dots. Here are the dot pictures of the squares of six and seven:

If you add a row of six dots to the first picture, you will have seven 6's. This shows that $36+6=42$ or $7\times6=42$. If you take away a row of dots from the second picture, you will have six 7's. This shows that $49-7=42$ or $6\times7=42$. Making dot pictures can help you learn the multiplication facts. For example, you can make a square with four dots to show 2×2. Another square with nine dots shows 3×3. A third could show 4×4, and so on.

Learning the multiplication facts takes time and study. But knowing the multiplication facts is necessary to become skilled at multiplying. You can become even better at arithmetic if you learn the division facts as you learn the multiplication facts. The division facts are the opposite of the multiplication facts.

Multiplying by one digit

Any number from 0 to 9 is called a *digit.* The number 26 is a two-digit number. The number 514 is a three-digit number. A digit gets its value from the place it occupies in a number. The first place on the right is for 1's, the next to the left is for 10's, the next for 100's, and so on. For example, in the number 347, the 3 means three 100's, the 4 means four 10's, and the 7 means seven 1's. Depending on its place, the digit 2 may mean two 1's, (2), two 10's (20), two 100's (200), or two 1,000's (2,000). You combine the idea of place value with the multiplication facts to multiply large numbers.

Here is an example of the steps needed to work a multiplication problem using more than one multiplication fact. There are 32 students in a class. Each student uses one sheet of paper a day. How many sheets of paper will be needed for three days? We could solve the problem by using addition: $32+32+32=96$. The class will need 96 sheets of paper for three days. Multiplication is quicker and easier. The number 32 is three 10's and two 1's. The basic idea is to multiply first the 1's by 3 and then the 10's.

$$\begin{array}{r} 32 \\ \times3 \\ \hline 96 \end{array}$$

First, you multiply the two 1's by 3. This is $3\times2=6$. You write the 6 in the 1's place in the product. Next, you multiply the three 10's by 3. This is $3\times30=90$. The 90 is nine 10's, and you write the 9 in the 10's place in the product. The answer is 96.

You multiply a larger number by one digit in much the same way:

$$\begin{array}{r} 302 \\ \times4 \\ \hline 1208 \end{array}$$

First, you multiply the two 1's by 4. This is $4\times2=8$. You write the 8 in the 1's place in the product. Next, you multiply the 0 or "no" 10's by 4. This is $4\times0=0$. You write the 0 in the 10's place in the product. Then you multiply the three 100's. This is $4\times300=1{,}200$. You write the 12 in the 100's and 1,000's place in the product. The answer is 1,208.

When you multiply a large number by one digit, you must multiply each digit of the larger number—the 1's, 10's, 100's, 1,000's, and so on—one at a time. As you multiply, write down the products of each of these multiplications—the 1's, 10's, 100's, 1,000's, and so on.

How to carry in multiplication

Students learn how to "carry" when they learn addition. When you add several numbers, there may be a 10 in the sum of the 1's column. You carry or add this 10 to the 10's column, usually by writing a small 1 above the

10's column. Carrying in multiplication is similar to carrying in addition:

```
Addition
 ¹12
  12
  12                    ¹12
  12                    ×8
  12                    ---
  12                     96
  12
  12
 ---
  96
```

When you add the eight 12's, the eight 2's total 16, or one 10 and six 1's. You write the six 1's in the 1's place in the sum. You add the 10 to the column of eight 10's by writing a 1 at the top of that column. Adding the 1's in the 10's column gives you nine 10's. You write nine 10's in the 10's place in the sum. To multiply 8×12, you multiply the 1's first. This is $8 \times 2 = 16$. You write the six 1's in the 1's place in the product. You write a 1 to be added to the product of 8×1 in the 10's place. This is $8 \times 1 = 8$ and $8 + 1 = 9$. You write the nine 10's in the 10's place in the product. *Be sure to multiply first. Then add the "carry number" to the product.*

Multiplying by large numbers

A multiplier that has more than one digit introduces a new idea in multiplication. This idea is the use of the *partial product*. You can learn this idea best from an example.

Jim wants to know how many cartons of milk his school used last month. It used 312 cartons each day for 23 days.

```
  312
  ×23
 ----
  936   Partial Product
 624    Partial Product
 ----
 7176   Product
```

The multiplier, 23, has two digits. It has two 10's and three 1's. You must use these as separate parts. First, you multiply 312 by the three 1's. This is $3 \times 2 = 6$. You write the 6 in the 1's place in the product. Then, $3 \times 1 = 3$ and $3 \times 3 = 9$. You write the 3 and the 9 in the 10's and 100's places in the product. This product of 3×312 is a partial product. Next, you multiply 312 by the two 10's. You write the product of this multiplication below the first product. You start this new partial product one place to the left, in the 10's place, because 312 is now being multiplied by 10's, not by 1's. First, $2 \times 2 = 4$. This is four 10's. You write the 4 below the 10's place in the first product. Next, $2 \times 1 = 2$ and $2 \times 3 = 6$. You write the 2 and the 6 in the 100's and 1,000's places of the second partial product. Now, the two partial products must be added together. The first partial product is 3×312 or 936. The second partial product is 20×312 or 6,240. Thus, $936 + 6{,}240 = 7{,}176$. The answer is that the school uses 7,176 cartons of milk in 23 days.

Multiplying by a three-digit multiplier is the same as by a two-digit multiplier. But there are three partial products instead of two. When you use the 100's part of the multiplier in a problem with a three-digit multiplier, remember to write this product beginning in the 100's place.

```
   123
  ×234
 -----
   492   First Partial Product
  369    Second Partial Product
 246     Third Partial Product
 -----
 28782   Product
```

Notice that the partial product of 2×123 is started in the 100's column directly under the 2. You do not write "carry numbers" when you are multiplying by larger numbers. You must carry in your mind. If you wrote in carry numbers, you could easily confuse them with the carry numbers from another part of the multiplier.

Multiplying by zero

Zeros in combination with other digits represent 10's, 100's, 1,000's, and so on. When there are zeros in a multiplier, you can shorten the work of multiplication.

```
   14          14
  ×20         ×20
  ---         ---
   00         280
  28
  ---
  280
```

In the example at the right, you can see that there will be no 1's in the 1's place. So you can write a 0 to show the 1's place, and write the product of the two 10's on the same line. This shortens the work. When you use this method with a three-digit multiplier that ends in zero, the difficulty comes in placing the second partial product:

```
   214
  ×320
 -----
  4280
 642
 -----
 68480
```

You begin the second partial product in the 100's place, because 3 represents 100's. Always check the place of the multiplier when you write its partial product.

An easy way to multiply by 10, 100, 1,000, and other multiples of 10 is to *annex zeros*. This means to place zeros at the end of a number.

$10 \times 2 = 20$ $\quad$ $100 \times 2 = 200$ $\quad$ $1{,}000 \times 2 = 2{,}000$

Stated as a rule, this means that *to multiply by* 10, *annex a zero to the multiplicand. To multiply by* 100, *annex two zeros to the multiplicand. To multiply by* 1,000, *annex three zeros to the multiplicand.* You can extend this:

$$400 \times 12 = 4{,}800$$

You multiply 12 by 4, and annex two 0's.

When you multiply larger numbers, there may be a zero in the 10's place of the multiplier.

```
    423
   ×302
 ------
    846
  12690
 ------
 127746
```

In this case, you write a zero in the 10's place of the sec-

ond partial product. This is to make sure you start the next partial product in the 100's place.

How to check multiplication

You should always check the answer in multiplication to be sure you have solved the problem correctly. You have seen that numbers can be multiplied in any order and the product remains the same. For example, $2\times4=8$ and $4\times2=8$. The best way to check a product is to change the places of the multiplier and multiplicand and do the multiplication again.

$$\begin{array}{r} 15 \\ \times12 \\ \hline 30 \\ 15 \\ \hline 180 \end{array} \qquad \begin{array}{r} 12 \\ \times15 \\ \hline 60 \\ 12 \\ \hline 180 \end{array} \qquad \begin{array}{r} 342 \\ \times153 \\ \hline 1026 \\ 1710 \\ 342 \\ \hline 52326 \end{array} \qquad \begin{array}{r} 153 \\ \times342 \\ \hline 306 \\ 612 \\ 459 \\ \hline 52326 \end{array}$$

The products are the same, but the partial products are different. If you make a mistake one way, you probably will not make it the other way. If your answers are different, you can locate your mistake. When you multiply a large number by one digit, you can check it easily by dividing the product by the single digit.

$$\begin{array}{r} 3425 \\ \times\quad 5 \\ \hline 17125 \end{array} \qquad \begin{array}{r} 3425 \\ 5\overline{)17125} \end{array}$$

Multiplication rules

These five rules will help you solve problems.

1. Remember that multiplication is a short way of adding equal numbers. The multiplier tells you how many times a number is to be multiplied.

2. Learn the meaning of the multiplication facts and learn to recall the facts quickly. Remember that a number multiplied by zero is zero and that a number multiplied by one is the same number. Also remember that zero multiplied by any number is zero.

3. Remember the methods for multiplying by one or more digits. You multiply the 1's, 10's, 100's, and 1,000's of the multiplicand one after the other and write the result in the product. When the multiplier has two or more digits, you must use partial products.

4. Place value has great importance in multiplication. Always keep the columns straight, and start the product under the digit you are using in the multiplier.

5. Learn to check the answer after working a problem in multiplication. You can do this by changing the places of the multiplier and multiplicand, and doing the multiplication again. John M. Smith

Mumbai, *mum BY* (pop. 11,914,398; met. area pop. 16,368,546), is the largest city in India. This island city is India's chief western seaport and the capital of Maharashtra state. For location, see **India** (political map). The city is often called by its former official name, Bombay.

The city. Several bridges link Mumbai with the mainland of India. Most of the city's hotels, museums, schools, and theaters are in the older part of Mumbai. This area forms most of the business and commercial center. It occupies the southernmost tip of the island. A newer, industrialized section called Greater Mumbai lies to the north. This area has many slums.

Famous structures in Mumbai include a huge archway called the Gateway of India, and the Prince of Wales Museum. The University of Bombay, founded in 1857, is the city's largest educational institution.

Railroads link Mumbai with other Indian cities. Santa Cruz Airport, 10 miles (16 kilometers) from downtown, handles domestic and international flights.

People. Most of Mumbai's people are Maharashtrians, members of a language group that speaks Marathi. A smaller number speak Gujarati, a related language (see **India** [Languages]). Minority groups from nearly every part of India live in Mumbai. Each speaks its own language and has its own way of life. Hindus make up the principal religious group in the city. The city also has many Muslims.

Many of Mumbai's wealthier residents have modern apartments in the older part of the city. But most of the people live in cheap housing developments in the outlying neighborhoods. Overcrowding is a serious problem.

Raghubir Singh, Woodfin Camp, Inc.

Crowds of people jam a Mumbai street. Mumbai is the largest city of India, and overcrowding has been one of its most serious problems for many years.

About a million people live in flimsy shanties without proper sanitation. Thousands of others sleep in the streets because they have no home at all.

To help ease overcrowding, the government of Maharashtra has developed a commercial, industrial, and residential area called New Mumbai. Known locally as Navi Mumbai, this area is on the mainland near Mumbai.

Economy. The chief industries of Mumbai include the production of cotton textiles, leather, and dock and railroad equipment. India's largest motion-picture producers have their studios in Mumbai. Exports from Mumbai include cotton, manganese, and manufactured goods. The city imports fertilizer, machinery, and wheat. Mumbai has many banks and insurance companies and is a major financial center.

History. Portuguese traders founded what is now Mumbai as a trading post in the 1530's. In 1661, King Charles II of England married a Portuguese princess and received what was then called Bombay as a wedding gift. In 1668, he rented the city to the East India Company (see **East India Company**).

By 1850, Bombay's population had risen to more than 500,000. The manufacture of cotton textiles formed the basis of the city's economy. During the American Civil War (1861-1865), a Union blockade prevented the Southern States from exporting most of their huge cotton crop. Bombay then became the world's chief cotton market. The opening of the Suez Canal in 1869 strengthened Bombay's economy by shortening the shipping time between India and Europe. During World War II (1939-1945), Bombay's port handled many ships carrying Allied troops and supplies.

In 1960, the Indian government divided the state of Bombay into two states—Maharashtra and Gujarat—according to language groups. Bombay became the capital of Maharashtra. Since the mid-1900's, riots have swept the city from time to time because of food shortages, disputes over language, and friction between Hindus and Muslims. In 1996, the city officially changed its name to *Mumbai,* its name in Marathi. Robert LaPorte, Jr.

Mumford, Lewis (1895-1990), was an American social critic, philosopher, and historian. Many of his books explore the relation between modern people and their environment. Several of them deal with city planning. *The City in History* (1961) won the 1962 National Book Award for nonfiction. It describes how human civilization is expressed in the development of cities.

Mumford wrote a four-volume philosophy of civilization called *The Renewal of Life.* The series included *Technics and Civilization* (1934), *The Culture of Cities* (1938), *The Condition of Man* (1944), and *The Conduct of Life* (1951). He also wrote several histories of architecture and studies of American culture. He was born in Flushing, New York. In 1975, Queen Elizabeth II of the United Kingdom knighted Mumford for his contributions to city planning in the United Kingdom.

Mummy is an embalmed body that has been preserved for thousands of years. The ancient Egyptians believed that the dead lived on in the next world, and that their bodies had to be preserved forever as they were in life. They believed that the body would serve a person in the next world and therefore spent much effort in developing methods of embalming. Thousands of years

University Museum, University of Pennsylvania

Field Museum of Natural History, Chicago

Field Museum of Natural History, Chicago

Peruvian and Egyptian mummies show how these ancient peoples cared for their dead. The body of a Peruvian girl was wrapped in a seated position in a patchwork cloth bundle called a *mummy bale, left.* A false head stuffed with cotton fabric peers out from the bale. Egyptian mummies, *center and right,* were wound tightly with linen and then laid out in painted coffins.

later, archaeologists found the preserved bodies in tombs. Many museums have one or more Egyptian mummies. The most famous are probably those of Ramses II and Tutankhamen, who were *pharaohs* (rulers) of Egypt.

Scientists now know what materials and processes the Egyptians used to mummify bodies. The process was simple when mummifying began, and gradually became more elaborate. Wealthy persons could afford a more expensive treatment than the poor. Ancient texts state that a complete treatment required 70 days. Embalmers removed the brain through a nostril by using a hook. They removed the internal organs, except the heart and kidneys, through an incision such as a surgeon makes. They usually filled the empty abdomen with linen pads, and sometimes with sawdust. Then they placed the body in natron (sodium carbonate) until the tissues were dried out. Finally, they wrapped the body carefully in many layers of linen bandages and placed it in a coffin. Sometimes there were two or more coffins, one inside the other. The coffins were made of wood or stone, and were either rectangular or shaped like the wrapped mummy. The mummy in its coffin was then placed in a tomb, along with many objects of daily use. The ancient Egyptians believed that the dead would need this equipment in the next world.

The dry climate in some parts of the world, such as Peru, Mexico, and Egypt, preserves dead bodies almost as well as Egyptian embalming methods did. Such naturally preserved bodies are sometimes called mummies also. The word *mummy* comes from *mumiya,* an Arabic word for embalmed body. Leonard H. Lesko

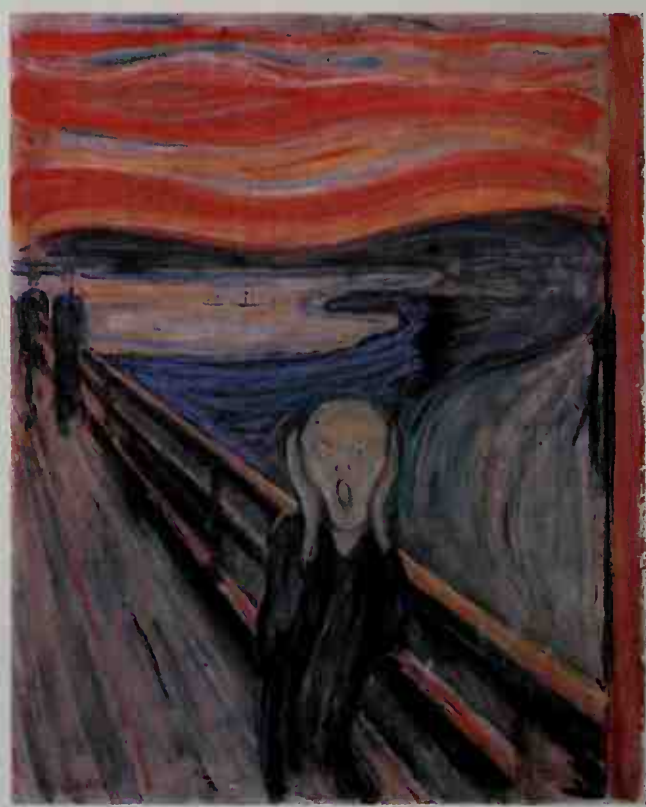
Mumps is a contagious disease that causes painful swelling below and in front of the ears. Mumps is also called *parotitis* because it affects chiefly the *parotid* (salivary) glands in the cheeks. The swelling occurs in these glands. Mumps is caused by a virus in the saliva of an infected person.

Symptoms appear about 18 days after contact with the mumps virus. They include fever, headache, muscle ache, and sometimes vomiting. Then swelling begins in one or both parotid glands. The pain of the swollen glands may make it difficult for the patient to chew or swallow. Mumps may also attack the salivary glands under the jaw. The swelling lasts about a week.



Most cases of mumps are not serious. But the disease may also affect other parts of the body. The mumps virus may attack the central nervous system, causing extremely high fever, severe headache, and nausea. It causes particularly painful swelling when it occurs in one or both testicles of an adult male. The virus also can infect the ovaries of a female. It only rarely makes a man or a woman *sterile* (unable to produce children).

About a third of the people who become infected with the mumps virus do not develop any symptoms. But they can still infect others. A person with mumps can transmit the disease as early as seven days before the swelling appears and up to nine days after.

No drug affects the mumps virus in a person who has the disease. But a mumps vaccine, which became available in the late 1960's, provides *immunity* (protection) from the disease. Neil R. Blacklow

Munch, *moongk,* **Edvard** (1863-1944), was a Norwegian artist. His most important works show individuals as helpless, isolated, and tormented by emotions.

Munch was born in Løten, near Oslo. His early paintings often deal with morbid themes linked to his frequent experiences with illness and death as a child. In 1889 he moved to Paris. There he learned how to express his ideas through line, color, and figure distortion from the style of such French artists as Paul Gauguin. Munch explored difficult relationships between men and women in works from 1892 to 1908 while he lived in Germany. Many of these works vividly express an emotion, such as fear, jealousy, a terrifying sense of isolation, or sexual desire. They rank among the earliest examples of expressionism, an art movement that attempts to convey the individual's inner feelings (see **Expressionism**). Munch returned to Norway in 1909. His late work became more realistic and less concerned with disturbing themes.

Casein on paper (1893); National Gallery, Oslo, Norway

Edvard Munch's painting *The Scream* illustrates the feeling of anguish and inner torment that appears in many of his works.

Munch was a talented printmaker. His woodcuts and lithographs were essential to the revival of graphic art that took place in the late 1800's. Munch was especially skillful with color prints. Pamela A. Ivinski

Munchausen, *MUHN CHOW zuhn,* **Baron,** was the name given to the narrator and central figure in an anonymous booklet of tall tales, *Baron Munchausen's Narrative of His Marvellous Travels and Campaigns in Russia.* It was first published in England in 1785. The booklet sold so widely that enlarged editions began to pour from the printing presses. These used extravagant boasts. The German translation appeared in 1786. The

author was an exiled German professor living in London named Rudolph Erich Raspe (1737-1794).

A real Baron Karl Friedrich Hieronymus Münchhausen (1720-1797) was a German aristocrat and officer who served in the Russian army in two wars against the Turks. Raspe may have known him. Münchhausen may have told some good stories, but he disapproved of the great lies the book attributed to him. Münchhausen tried in vain to escape the visitors that the publication brought to him. He died in grief at being named the world's biggest boaster. His name is still used to describe an exaggerator or boaster. Klaus L. Berghahn

Mung bean. See **Bean** (Kinds of beans).

Munich, *MYOO nihk* (pop. 1,229,026), is the third largest city in Germany. It ranks next in population to Berlin and Hamburg. Munich lies in the southeastern part of Germany on the Bavarian plain. For location, see **Germany** (political map).

The German name for Munich is *München,* which means *Place of the Monks.* Tradition says that this name goes back to the 700's, when an outpost of the rich abbey of Tegernsee was stationed there.

Munich is remembered today for its connection with the Nazi Party, which developed out of a small political group founded there in 1919. It was the site of Adolf Hitler's "Beer Hall Putsch" of 1923. Hitler attempted a revolution to seize power at a mass meeting in a Munich beer hall (see **Hitler, Adolf** [The Beer Hall Putsch]). In 1938, Britain, Italy, France, and Germany signed an agreement at Munich to give Czechoslovakia's Sudetenland to Germany (see **Munich Agreement**).

The Isar River flows through Munich toward the Danube River. The Maximilianeum, the seat of the Bavarian Parliament, lies along the banks of the Isar in Munich. It was built in the mid-1800's.

Munich lies less than 100 miles (160 kilometers) from Brenner Pass in the Alps on the border between Austria and Italy. The location of Munich has made the city a major transportation center linking northern and southern Europe.

David Falconer, Frazier Photolibrary

Munich's New City Hall stands in the busy Marienplatz, a large square in the old section of the city.

Industries. Munich is one of the country's most important centers of economic activity. Its major industries include electronics, food processing, printing and publishing, and the production of chemicals, machine tools, optical instruments, and textiles. Munich is well known for its breweries. Munich was formerly famous for its handicrafts and for its production of stained glass for church windows.

Important buildings. Three of the most famous buildings in Munich are the Cathedral, the Palace, and the German Museum. But beautiful palaces, churches, and public buildings can be found throughout the city. The German Museum is one of the most famous museums in the world for exhibits in technology and science. The imposing State Library contains over a million books and more than 50,000 manuscripts. The National Theater, one of the largest theaters in Germany, was bombed and destroyed during World War II (1939-1945). It was completely restored after five years of labor. The building was reopened officially in 1963.

Three famous museums were almost destroyed by the bombings during World War II. They were the old Pinakothek, the new Pinakothek, and the Glyptothek. Some of the valuable paintings and sculptures in these museums were saved, reassembled, and exhibited after the war.

Ludwig-Maximilian University in Munich has about 25,000 students, and a library of over 700,000 volumes. Founded in 1471, the university was moved to Munich from Landshut in 1826.

History. Munich was founded in 1158 by Duke Henry the Lion. In 1255, the city became the seat of a family of nobles called the House of Wittelsbach. The Wittelsbachs ruled Munich and the rest of Bavaria until World War I ended in 1918. From 1919 to the end of World War II, Munich was a stronghold of Nazism (see **Nazism**). Allied bombings destroyed much of the city during World War II. After the war, Munich was rebuilt in a way that restored much of its traditional appearance. Melvin Croan

Munich Agreement, *MYOO nihk,* approved in September 1938 in Munich, Germany, was the acceptance by Britain and France of Germany's demand for certain territory in Czechoslovakia. The agreement involved the Sudetenland region of Czechoslovakia, which had about 800,000 Czechs and 2,800,000 people of German ancestry. This region covered about 11,000 square miles (28,500 square kilometers). It included most of Czechoslovakia's industry, communications network, military outposts, and vital natural defenses. The agreement included a promise by Germany to end its aggressive expansion, and Britain and France viewed it as an attempt to avoid war. But Germany violated the agreement, drawing Europe closer to the beginning of World War II (1939-1945).

Background. German dictator Adolf Hitler had claimed that the government of Czechoslovakia was unfair to the German residents of the Sudetenland and that their land should be part of Germany. He had prepared his troops for a military take-over of the region.

Neville Chamberlain, prime minister of Britain, attempted to reach a peaceful settlement. He twice met with Hitler in September, but the negotiations failed. Finally, Chamberlain suggested a conference including leaders Édouard Daladier of France and Benito Mussolini of Italy. It took place in Munich on September 29 and 30 and resulted in the Munich Agreement.

The pact allowed Germany to occupy the Sudetenland. In return, Hitler promised that the Sudetenland would be the "last territorial claim I have to make in Europe." The agreement further provided for establishment of an international commission to supervise the occupation, elections in other areas of dispute, a joint guarantee for the independence of the diminished Czechoslovakia, and adjustment of claims made by Poland and Hungary. Only the first and last provisions occurred. The Munich Agreement at first seemed to avoid war. Chamberlain reported to cheering crowds in England "peace with honor" and "peace in our time."

Consequences. A few months after the conference, Hitler broke his promise and had German troops take control of Czechoslovakia. The Soviet Union lost faith in the ability of Britain and France to preserve peace and made a pact with Germany to avoid war. Hitler came to believe Britain and France would not honor their pledge to defend Poland and launched an attack on that country on Sept. 1, 1939. Britain and France promptly declared war on Germany, and World War II began.

The Munich Agreement became a classic example of an ill-advised policy of *appeasement* (concession). After Munich, agreements with an aggressive nation were thought to invite war rather than prevent it. Such agreements are still sometimes referred to as "another Munich." Diane Shaver Clemens

Municipal government. See City government.

Muñoz Marín, *moo NYOHS mah REEN,* **Luis,** *loo EES* (1898-1980), was the first elected governor of Puerto Rico and its chief political leader for over 25 years. Previous governors had been appointed by the President of the United States. Muñoz Marín served as governor from 1949 to 1965. Under his leadership, Puerto Rico became a self-governing commonwealth of the United States in 1952. He also began Operation Bootstrap, a comprehensive development program that brought land reform, roads, and schools to neglected areas of Puerto Rico (see **Puerto Rico** [Building a democracy]).

Muñoz Marín was born in San Juan. He studied law in the United States. In 1938, he organized the Popular Democratic Party in Puerto Rico. Nathan A. Haverstock

Munro, Alice (1931-), is a Canadian short-story writer. Munro's fiction excels in revealing the larger and darker meanings in seemingly ordinary events. She describes a fractured and changing world, in which characters search for ways to unify their experiences.

Munro was born in Wingham, Ont. Her given and family name was Alice Ann Laidlaw. She was married to James Munro from 1951 to 1976. Her first collection of stories, *Dance of the Happy Shades* (1968), explores life in a fictional small Ontario town similar to the one in which she was born and raised. *Lives of Girls and Women* (1971) is a series of linked stories. The book follows Del Jordan from her childhood through a series of crises she experiences in religion, sex, and art.

Many of Munro's later stories depict the complications of marriage and the difficulties her characters encounter in knowing their own motivations. They have been collected in *Something I've Been Meaning to Tell You* (1974), *Who Do You Think You Are?* (1978, published in the United States as *The Beggar Maid*), *The Moons of Jupiter* (1982), *The Progress of Love* (1986), and *Friend of My Youth* (1990). Ronald B. Hatch

Munro, Hector Hugh (1870-1916), was a British writer who wrote under the pen name Saki. Munro is best known for his unsettling and cleverly constructed short stories, often with trick endings. Many of the stories satirize British society of the early 1900's. Munro also wrote two novels, *The Unbearable Bassington* (1912) and *When William Came* (1913). *The Complete Works of Saki* was published in 1976.

Munro was born in Akyab (now Sittwe), Burma. He was taken to England when he was 2 years old. Munro became a well-known London journalist. He died in battle in France during World War I. Garrett Stewart

Munsee Indians, *MUN see,* formed the Wolf clan of the Delaware Indian tribe. The Munsees lived around the headwaters of the Delaware River and along the Hudson River, and they were called the people of the stony country. White settlers drove them from the Delaware River region about 1740, and the Munsees settled along the Susquehanna River. They later migrated to other areas, largely the Midwest and Southwest in the United States and the Canadian province of Ontario. See **Delaware Indians.** Roberta Miskokomon

Munsey, *MUN see,* **Frank Andrew** (1854-1925), was a pioneer publisher of low-priced magazines and newspapers. He had little education or financial backing but made nearly $20 million. He started *Munsey's Magazine* in 1889. The magazine's circulation reached 650,000 by 1900. Munsey built a successful grocery chain and used his profits to buy 17 newspapers. He often bought competing papers and combined them into one. Munsey was born in Mercer, Me. Joseph P. McKerns

Muon, *MYOO ahn,* is a type of elementary particle that closely resembles an electron but has a greater mass. An elementary particle does not consist of smaller units. Both muons and electrons belong to a family of such particles called *leptons.* The muon carries a negative charge like an electron, but it is about 207 times heavier. Muons are *unstable,* and so they *decay* (break down) to form electrons and other lighter particles.

The muon was discovered independently by two groups of scientists in 1937. These groups were Carl D. Anderson and Seth H. Neddermeyer of California Institute of Technology and Jabez C. Street and Edward C. Stevenson of Harvard University. Scientists have learned about magnetic fields in certain substances by observing muon decay in those materials. Stanley G. Wojcicki

Muppet. See **Henson, Jim.**

Mural is a picture or design on a wall or ceiling. Most murals decorate interiors of buildings, but some are used as exterior ornament. Murals usually relate to the architecture they decorate. Murals can alter a viewer's perception of space by creating illusionary openings in walls and ceilings. They can also make space appear more confining. Most murals are public art, meant to be seen and understood by a broad audience.

Artists have used several techniques to create murals,

Biblical scenes painted by the Italian artist Giotto cover the walls of the Scrovegni, or Arena, Chapel in Padua, Italy. These beautiful frescoes, which date from the early 1300's, rank among the masterpieces of Italian mural painting.

Fratelli Fabbri Editori, Milan, Italy

including fresco, the most common technique; encaustic; tempera; oil painting; and enamel or ceramic on metal. Sometimes, artists paint on a canvas that is later attached to a wall in a technique called *marouflage.* Some murals, called *mosaics,* are designs composed of pieces of glass, stone, or other material.

The mural is one of the oldest art forms. Prehistoric people decorated caves with murals of animals. Ancient Egyptians painted murals with flat, linear images. Greeks and Romans decorated walls with pictures of gardens, buildings, gods, and heroes. The greatest European murals were created during the Renaissance. The Italian artist Giotto revolutionized mural painting in the early 1300's with his dramatic and realistic Biblical scenes. In the 1400's and 1500's, Italian artists, such as Andrea Mantegna, Masaccio, Piero della Francesca, and Raphael, further developed Giotto's style. The greatest mural painter of the Renaissance was Michelangelo. Baroque and rococo artists of the 1600's and 1700's drew on Renaissance techniques to paint murals that made walls and ceilings seem to dissolve into space.

Mural art declined in prominence in the 1800's. However, at the end of the century, French painter Puvis de Chavannes and American John La Farge had revived the art form. Murals gained popularity in Mexico during the 1920's when José Clemente Orozco, Diego Rivera, and David Siqueiros created murals depicting Mexican legends and history. In the 1930's and early 1940's, the U.S. government sponsored over 2,000 murals in public buildings by such artists as Thomas Hart Benton, Reginald Marsh, and Ben Shahn. Since the 1960's, many artists have painted murals to draw attention to poverty, racism, and other social and political issues, thus permitting murals to serve as propaganda art.

John W. Keefe

Murasaki Shikibu, *MOO rah SAH kee SHEE kee BOO* (A.D. 975?-1031?), also called Lady Murasaki, is the most famous writer of early Japanese literature. Her long novel *The Tale of Genji* is generally considered the greatest work of Japanese fiction. The novel begins with the romantic adventures of Prince Genji, the "Shining Prince." He exemplifies courtliness and the unique Japanese sensitivity to nature. The tone grows somber as the book follows the next two generations of Genji's family. The themes of death, frustration in love, and a Buddhist sense of human impermanence dominate the story. Lady Murasaki flawlessly handled a large cast of characters, portraying them with a psychological realism that did not appear in Western literature until centuries later.

Lady Murasaki was one of several gifted writers who served as ladies in waiting to Japanese empresses during the 1000's. In addition to *The Tale of Genji,* she wrote poetry and a diary famous for its witty portrayal of her contemporaries. Laurel Rasplica Rodd

Murat, *myoo RA,* **Joachim,** *zhoh ah KEEM* (1771?-1815), was the most famous French cavalry commander under Emperor Napoleon I. From 1808 to 1814, Murat ruled the Kingdom of Naples in southern Italy as King Joachim I. Napoleon made him a general in 1799 for defeating the Turks in Egypt. Murat's cavalry attacks helped Napoleon win battles at Austerlitz, Jena, and Friedland between 1805 and 1807.

Murat deserted Napoleon when the emperor was defeated at Leipzig in 1813. But when Napoleon escaped from his prison on the island of Elba in 1815, Murat tried to win all Italy for him. The Austrians, however, defeated Murat. After the Battle of Waterloo in 1815, he was quickly captured, condemned, and executed.

Murat was born in Bastide, France, near Cahors.

In 1800, he married Napoleon's sister Caroline, a step that helped his career. Eric A. Arnold, Jr.

Murder. When one person intentionally kills another without legal justification or excuse, the crime is called *murder.* The clearest example of this is a case where one person deliberately kills another because of hatred, envy, or greed. But there are also situations where a killing is considered murder even when no specific intent to kill exists. For example, a person who accidentally kills someone while committing a robbery is guilty of murder. The fact that the person is committing a serious crime indicates that he or she has a reckless disregard for human life and safety. This takes the place of intent to kill. The penalty for murder is a long prison sentence or death. But many national, state, and provincial governments have done away with the death penalty.

A killing that has legal justification is called *justifiable homicide.* For example, a killing in self-defense would be a justifiable homicide. The law regards a purely accidental killing as an *excusable homicide.* For example, if a pedestrian steps in front of a carefully driven automobile and is killed, the accident would be considered an excusable homicide. When a person in a fit of anger intentionally kills another person after the victim has provoked the attack, the killing is called *voluntary manslaughter.* When a person's death results from reckless driving or other extreme negligence on the part of the killer, the offense is called *involuntary manslaughter.* The penalties in most cases of manslaughter are less severe than those for murder. Charles F. Wellford

Murdoch, *MUR dahk,* **Iris** (1919-1999), was a British novelist known for her philosophical novels. Her characters face difficult moral choices in their search for love and freedom and are often involved in complex networks of love affairs. Some critics have complained that Murdoch's characters are mere puppets used to act out philosophical ideas. But others have praised her fiction for its wit and psychological insight.

Some of Murdoch's novels expose the dangers of abstract systems of behavior that can cut people off from spontaneous, loving relationships. *Under the Net* (1954) and *A Fairly Honourable Defeat* (1970) are examples. *The Bell* (1958) examines the relationships among the members of a religious commune. In *A Severed Head* (1961), Murdoch portrays three couples whose unfaithful sexual conduct illustrates their shallow, self-centered philosophies. Her other novels include *The Black Prince* (1973), *The Sea, the Sea* (1978), *The Good Apprentice* (1986), and *The Book and the Brotherhood* (1988).

Jean Iris Murdoch was born July 15, 1919, in Dublin. She lectured in philosophy from 1948 to 1963 at Oxford University in England. In 1987, Queen Elizabeth II made her a Dame Commander in the Order of the British Empire, and she became Dame Iris Murdoch. Jane Marcus

Murdoch, *MUR dahk,* **Rupert** (1931-), is an Australian-born publisher who owns many newspapers and magazines in Australia, the United Kingdom (U.K.), the United States, and other countries. His publications range from *The Times* of London, an influential British daily, to the *New York Post,* a sensational U.S. daily. He is also owner or part-owner of a motion-picture studio, TV stations, and book-publishing firms. Murdoch is known for making financially struggling operations profitable.

Murdoch's most extensive holdings are in Australia, where he controls over half of the nation's newspaper circulation. His newspapers there include *The Australian,* a national daily, and the *Daily Mirror Telegraph* of Sydney. He also is part-owner of one of the nation's airlines. Murdoch controls his properties through News Corporation Limited and its subsidiaries.

In the United States, Murdoch owns Twentieth Century Fox Film Corporation; the Fox Broadcasting Company, a television network; and the Los Angeles Dodgers, a professional baseball team. In the U.K., he publishes *The Sun, The Times,* and other newspapers. Keith Rupert Murdoch was born on March 11, 1931, in Melbourne. In 1985, he became a U.S. citizen. Michael Emery

Muriatic acid. See Hydrochloric acid.

Murieta, *moo ree AY tah,* **Joaquín,** *hwah KEEN,* was the name given to a famous bandit during the California gold rush of the mid-1800's. He became a hero of Spanish-speaking people who had been discouraged from entering the gold fields because of a $20 monthly tax placed on foreign miners in 1850. No one knows if a real Joaquín Murieta existed. There were as many as five bandits in the gold fields known only as *Joaquín.* In July 1853, California rangers killed two Mexicans and later identified one of them as Joaquín Murieta. But this person's true background is unknown.

The legend of Murieta grew after publication of the book *The Life and Adventures of Joaquín Murieta, the Celebrated California Bandit* (1854) by American writer John Rollin Ridge. Ridge described Murieta as a peaceful miner who became an outlaw after white Americans stole his claim and attacked his family. The story became believable because of later references to Murieta in works by several respected writers, including American historians Hubert H. Bancroft and Theodore Hittell and the Chilean poet Pablo Neruda. Feliciano M. Ribera

Murillo, *moo REE lyoh,* **Bartolomé Esteban,** *BAHR toh loh MAY ays TAY bahn* (1618-1682), was a Spanish painter of the 1600's. He is considered the best interpreter of the gentle, optimistic side of Christianity. He is known for the warmth and humanity of his paintings.

Murillo's painting *The Immaculate Conception* shows the delicate beauty and fine shadings of light and atmosphere that characterize his work. Like many of Murillo's paintings, this work has a gentleness critics of the early 1900's found too sentimental. Today, his complex spiraling compositions, fluid brushwork, fine drawing, and subtle colors are much admired. Murillo also painted dignified and flattering portraits and scenes of daily life. He is one of the few artists who created realistic and sympathetic paintings of children.

Murillo was born on Jan. 1, 1618, in Seville. His paintings before 1645 were influenced by the realism and dark coloring found in the work of artists from southern Spain. In 1645, the Franciscan Order in Seville gave Murillo his first important commission. That same year, Murillo visited painter Diego Velázquez in Madrid. There he was also inspired by Flemish and Venetian masters. In his later work, Murillo became more concerned with problems of light, color, and atmosphere. By 1660, he was Spain's most popular painter. Marilyn Stokstad

Murmansk, *moor MAHNSK* (pop. 381,800), is Russia's chief port on the Arctic Ocean. It is the world's largest

city north of the Arctic Circle. The warm Gulf Stream keeps the harbor free of ice the year around. Murmansk stands on a level, treeless plain on the northern part of the Kola Peninsula. It borders the Kola Inlet, an arm of the Arctic Ocean. For the location of Murmansk, see **Russia** (political map).

Murmansk is a fishing and shipbuilding center. It has fish canneries; metal, woodworking, and net and barrel factories; and refrigerating plants. Exporters ship fish, lumber, and minerals. The city has a polar research station. A railroad links Murmansk with St. Petersburg. Murmansk was founded in 1915. During World War II (1939-1945), the Allies used the port to ship supplies to parts of the Soviet Union that were controlled by Germany. Zvi Gitelman

Murphy, Audie, *AW dee* (1924-1971), won fame as the most decorated United States soldier of World War II (1939-1945). He received 24 medals from the U.S. government, 3 from France, and 1 from Belgium. He later became a motion-picture actor.

Audie Leon Murphy was born in Kingston, Tex., near Greenville. He enlisted in the Army in 1942 and was appointed a second lieutenant in 1944. Murphy served in North Africa and Europe. On Jan. 26, 1945, German forces attacked his unit near Colmar, France. Murphy jumped on a burning tank destroyer and used its machine gun to kill about 50 enemy troops. He received the Medal of Honor, the nation's highest military award.

Oil painting on canvas (1678); Prado Museum, Madrid (MAS)

Murillo's *The Immaculate Conception* honors the Virgin Mary's freedom from original sin. The painting shows the spiritual quality typical of the artist's later work.

Murphy began his motion-picture career in 1948. His films included *The Red Badge of Courage* (1951) and *To Hell and Back* (1955). Murphy died in an airplane crash.

Samuel J. Ziskind

U.S. Army

Audie Murphy

Murphy, Emily Gowan (1868-1933), was a Canadian social reformer and author. She helped win legal and political rights for Canadian women.

In the early 1900's, Murphy helped establish a court in Edmonton, Alta., that handled cases involving women. From 1916 to 1931, she served as the court's first judge and as the first woman magistrate in the British Empire. A book she wrote about drug abuse, *The Black Candle* (1922), helped lead to the passage of drug laws in Canada.

In 1927, Murphy led a group of five women in a court battle to determine whether women were "persons" under the British North America Act, which then served as Canada's constitution. The Privy Council in England, the highest judicial authority in the British Empire, ruled in the women's favor in 1929. The council's ruling enabled women to serve in the Canadian Senate.

Murphy wrote several books under the pen name of "Janey Canuck," including *The Impressions of Janey Canuck Abroad* (1901) and *Janey Canuck in the West* (1910). Murphy was born in Cookstown, Ont. Patricia Monk

Murray, James (1721?-1794), was a British soldier who became the first British governor of Quebec. He was born near Edinburgh, Scotland, and went to America in 1757. He fought the French at Louisbourg in 1758.

Murray served as one of the three brigadiers under General James Wolfe in the successful battle against the French on the Plains of Abraham outside Quebec City. After the victory, Murray was left in command of the city. He later defended it against a French army led by General François de Lévis.

Murray was made governor of the Quebec region in 1760. Three years later, when French rule ended, he became governor of the main area gained from the French in Canada. He faced many problems in the relations between the English and the Indians and between the French Canadians and English officers and merchants. Some men working under him accused him of favoring the French. Murray was recalled to England in 1766. But he was cleared of all charges. Phillip Buckner

Murray, Philip (1886-1952), succeeded John L. Lewis as president of the Congress of Industrial Organizations (CIO) in 1940, and held that post until his death. He helped establish World War II government labor policies. He saw to it that the CIO unions kept their "no-strike" pledge during the war. He also served on the National Defense Mediation Board.

Murray rose to his CIO position after 36 years as a labor union organizer and leader. He advanced in the United Mine Workers to the post of vice president, which he held from 1920 to 1942. Murray ended a long friendship with John L. Lewis soon after he succeeded him as president of the CIO.

When the CIO began organizing the steel industry in 1935, Murray became chairman of the organizing committee. He served as the first president of the United Steelworkers of America from 1942 to 1952. In the late 1940's, Murray led a successful fight to oust Communist-dominated unions from the CIO. He led the steelworkers in three national strikes after World War II. Pensions and union security were two of the major issues of these strikes.

Murray was born in Blantyre, Scotland, the son of a coal miner. In 1902, he moved to the United States with his family, and began working in the mines at the age of 16. Murray argued with a foreman from the mine soon after he began working, and lost his job. The other miners went on strike in sympathy with him. Murray served on Woodrow Wilson's War Labor Board and on the National Bituminous Coal Production Committee during World War I (1914-1918). He was the coauthor, with Morris L. Cooke, of *Organized Labor and Production* (1940). Jack Barbash

Murray River is the longest permanently flowing river in Australia. It is also an important source of irrigation. The Murray River system includes the Darling, Lachlan, and Murrumbidgee rivers, and drains an area larger than that of France and Spain combined. For location, see **Australia** (terrain map).

The Murray rises in the Australian Alps near the eastern boundary of Victoria. It flows northwestward and forms the boundary between Victoria and New South Wales. It then crosses eastern South Australia and empties into Encounter Bay, south of Adelaide. The Murray River is 1,609 miles (2,589 kilometers) long. With the Darling River, it forms a system 2,310 miles (3,718 kilometers) long. Small recreational boats operate on the Murray. But the river is not navigable into the interior by ships.

A system of dams helps irrigate about $1\frac{1}{2}$ million acres (610,000 hectares) of land. The dams were built under the Murray River Agreement made in 1915 by New South Wales, South Australia, and Victoria. The Snowy Mountains Scheme—begun in the mid-1900's—includes 16 large dams and several small ones. It directs water into the Murray and Murrumbidgee rivers. It provides hydroelectric power for Victoria and New South Wales, and enough water to irrigate about 1,000 square miles (2,600 square kilometers).

One result of the irrigation has been a high salt content in the soil over a large area. The Murray-Darling Basin Commission was established in 1988 to try to solve this ecological problem. D. N. Jeans

Murre, *mur,* is a type of sea bird that lives on rocky coasts of the North Atlantic and North Pacific. Great colonies consisting of thousands of murres crowd the rock ledges during the breeding season. A murre is from 16 to 17 inches (41 to 43 centimeters) long. It has short wings. The bird is brownish-black above and white on the breast and throat.

The female murre hatches a single large, pointed egg, which it lays on the bare stone. The egg varies from white to blue and green and usually has black, brown, or lavender spots.

Scientific classification. Murres make up the genus *Uria* in the auk family, Alcidae. The scientific name for the common murre is *Uria aalge.* Fritz L. Knopf

Murrow, Edward R. (1908-1965), was an American radio and television broadcaster. He won fame during World War II (1939-1945) for his on-the-scene radio broadcasts describing German bombing attacks on London. His listeners in America could hear the bombs exploding in the background.

Egbert Roscoe Murrow was born near Greensboro, N.C. He changed his name to Edward while in college. Murrow became European director of the Columbia Broadcasting System (now CBS Inc.) in 1937. He turned to radio newscasting shortly before World War II.

Edward R. Murrow Foundation

Edward R. Murrow

Murrow narrated the TV program, "See It Now," from 1951 to 1958. He started a new style of TV newscasting with on-the-scene reporting that told about issues in everyday terms. In the most famous show of the series, Murrow attacked Joseph R. McCarthy. McCarthy was a U.S. senator whose investigations of Communist influence in the government had caused a national controversy (see **McCarthy, Joseph R.**). From 1953 to 1959, Murrow narrated "Person to Person," a TV program that featured interviews with famous people in their homes. He served as director of the U.S. Information Agency from 1961 to 1964. Keith P. Sanders

Muscat, *MUHS kat* (pop. 30,000; met. area pop. 250,000), is the capital of Oman. It lies on the country's northeast coast, along the Gulf of Oman (see **Oman** [map]). Muscat, also spelled *Masqat,* became Oman's chief seaport and trading center in the 1500's. In the early 1970's, the main port and trade activities were

WORLD BOOK illustration by Trevor Boyer, Linden Artists Ltd.

The common murre is a sea bird that nests in colonies on the rocky coasts of the North Atlantic and North Pacific.

shifted to the nearby suburb of Matrah. Muscat is important because of its location on the Gulf of Oman, the route for oil tankers leaving the Persian Gulf. Two Portuguese forts that date from the late 1500's and the palace of the sultan of Oman, built in the 1970's, dominate the city. Muscat has many old, one- and two-story whitewashed buildings. Most of the people work in commerce or for the government.

Muscat and its more modern suburbs are called the Capital Area. The Capital Area is a booming district that includes an international airport, an oil tanker loading zone, military bases, and a deepwater port. Muscat dates from ancient times. Portugal controlled Muscat from about 1507 to 1650. Robert Geran Landen

Muscat and Oman. See Oman.

Muscle is the tough, elastic tissue that makes body parts move. All animals except the simplest kinds have some type of muscle.

People use muscles to make various movements, such as walking, jumping, or throwing. Muscles also help in performing activities necessary for growth and for maintaining a strong, healthy body. For example, people use muscles in the jaw to chew food. Other muscles help move food through the stomach and intestines, and aid in digestion. Muscles in the heart and blood vessels force the blood to circulate. Muscles in the chest make breathing possible.

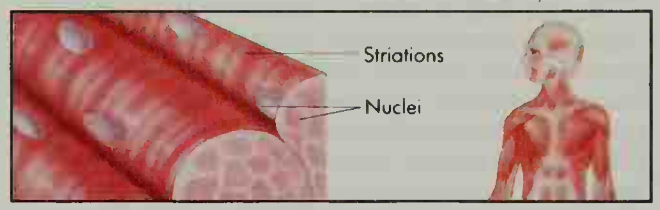
Muscles are found throughout the body. As a person grows, the muscles also get bigger. Muscle makes up nearly half the body weight of an adult.

This article primarily discusses the muscles of human beings. The last section describes muscles in other animals.

Kinds of muscles

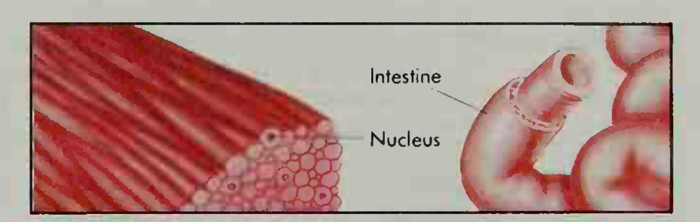
The human body has more than 600 major muscles. About 240 of them have specific names. There are two main types of muscles: (1) skeletal muscles and (2) smooth muscles. A third kind of muscle, called *cardiac muscle,* has characteristics of both skeletal and smooth muscles. It is found only in the heart.

Skeletal muscles help hold the bones of the skeleton together and give the body shape. They also make the body move. Skeletal muscles make up a large part of the legs, arms, abdomen, chest, neck, and face. These muscles vary greatly in size, depending on the type of job they do. For example, eye muscles are small and fairly weak, but the muscles of the thigh are large and strong.



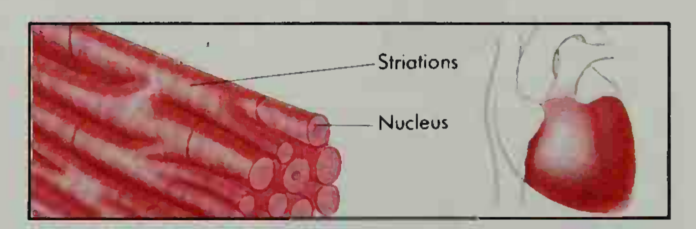
All muscles are made up of cells called *muscle fibers.* Each skeletal muscle is composed of thousands of long, cylindrical muscle fibers. When viewed under a microscope, these fibers show alternating light and dark bands called *striations.* For this reason, skeletal muscles are also called *striated muscles.* The striations occur because thick and thin *filaments* (strands) repeatedly overlap each other. The thick filaments consist of a protein called *myosin.* The thin filaments are made up chiefly of the protein *actin.*

Muscle fibers have a variety of other specialized parts. Each skeletal muscle fiber has many elements called *nuclei.* These nuclei contain growth-producing substances that repair or remake various parts of the muscle fiber as they wear out. Each muscle fiber also has thousands of tiny sausage-shaped *mitochondria.* These structures produce the energy that the fiber needs in order to live and do its work.



Kinds of muscles

The human body has three kinds of muscles: skeletal, smooth, and cardiac. Skeletal muscle fibers have bands called *striations.* Each fiber also has many core elements called *nuclei.* Smooth muscles have no striations and only one nucleus in each fiber. Cardiac muscle has striations and a single nucleus in each fiber.



WORLD BOOK illustrations by Charles Wellek

Skeletal muscles

Smooth muscles

Cardiac muscle

Muscle fibers are held together by *connective tissue.* The ends of most skeletal muscles are joined to bones by a tough, flexible connective tissue called *tendon.* One end of the muscle is attached to a bone that does not move when the muscle *contracts* (draws together). This end of the muscle is called the *origin.* The other end, called the *insertion,* is attached to a bone that moves when the muscle contracts.

When a person stands erect, many skeletal muscles contract to make the body rigid. The skeletal muscles also can make one part of the body move while another part stays stiff. Skeletal muscles act both ways because they work in pairs. One muscle of each pair is called the *flexor.* It bends a joint and brings a limb closer to the body. The other muscle, the *extensor,* does the opposite. For example, the *biceps* muscle in the front of the upper arm is a flexor. When this muscle contracts, the elbow bends and the forearm and hand move toward the shoulder. The *triceps* muscle in the back of the upper arm is an extensor. When it contracts, the elbow straightens and the forearm and hand move away from the shoulder. At the same time, the biceps relaxes so the triceps can pull it back to its original length.

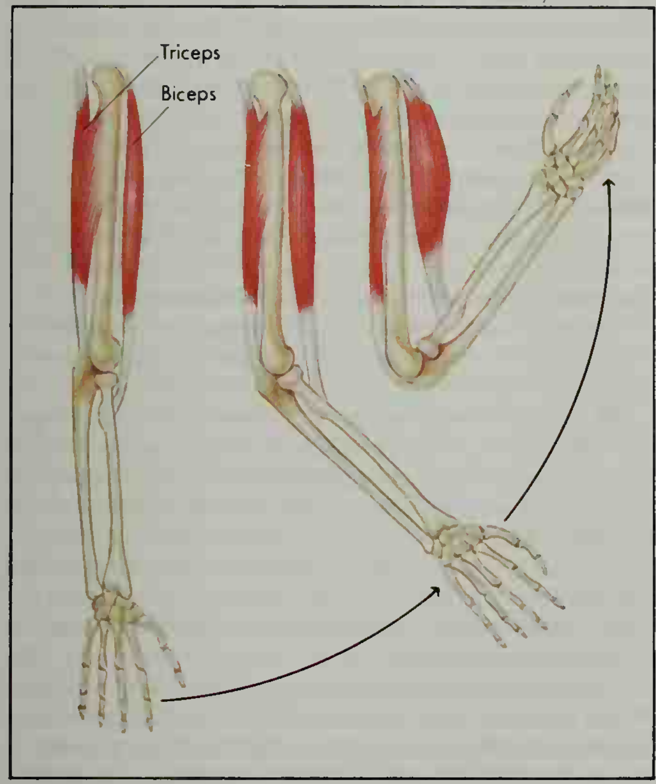
Skeletal muscles contract and pull on the bones they attach to when a nerve stimulates them. They usually

move *voluntarily* (under conscious control) and are sometimes called *voluntary muscles.* But skeletal muscles also may move *involuntarily* (without conscious control). For example, involuntary movement occurs when a person jerks his or her hand away from a hot object before thinking about doing it.

Skeletal muscles adapt to exercise in special ways, depending on how they are required to work. For example, muscles grow larger and stronger if a person lifts heavy weights for a short period of time each day. Such exercise causes muscle nuclei to increase production of thick and thin filaments in each exercised muscle fiber. In addition, bone and tendon grow stronger. Muscles adapt differently if a person regularly performs lighter exercise for long periods—such as 30 minutes of bicycling, running, or swimming. In this case, muscle fibers increase their ability to produce energy needed to keep up such muscular work.

Smooth muscles are found in various organs of the body. For example, smooth muscles are found in the walls of the stomach, intestines, blood vessels, and bladder. The fibers of smooth muscles are not striated like those of skeletal muscles. They also are smaller than skeletal muscle fibers and have only one nucleus.

Smooth muscles operate slowly and automatically in a natural, rhythmic pattern of contraction followed by relaxation. In this way, they control various body processes. For example, the steady action of smooth muscles in the stomach and intestines moves food along for digestion. Because they are not under conscious control



Skeletal muscles The human body has more than 600 major muscles. About 240 of these muscles have specific names. The illustrations below show some of the most important external skeletal muscles. These muscles are identified by their Latin names, which are the names used by medical personnel.

WORLD BOOK illustrations by Charles Wellek

How skeletal muscles move a limb

Skeletal muscles work in pairs, as shown in the example below. The elbow straightens when the triceps muscle *contracts* (draws together). The elbow bends as the biceps muscle contracts.

WORLD BOOK illustrations by Charles Wellek

by the brain, smooth muscles are also known as *involuntary muscles.*

Smooth muscles are stimulated by a special set of nerves that belong to the *autonomic nervous system,* and by body chemicals (see **Nervous system** [The autonomic nervous system]). In certain circumstances, the autonomic nerves and hormones act to change the speed and strength of smooth muscle contractions. For example, they slow the pace of contractions in the intestines if a person feels fear or anxiety. They can even stop contractions in the intestines if these feelings become severe. For this reason, people under emotional stress often find it difficult to digest food.

Cardiac muscle makes up the walls of the heart. When cardiac muscle cells contract, they push blood out of the heart and into the arteries. The blood then circulates throughout the body, bringing nourishment to all body cells. Cardiac muscle has characteristics of both skeletal and smooth muscles. Like skeletal muscle fibers, cardiac muscle cells have striations. Like smooth muscle fibers, each cardiac muscle cell has only one nucleus and contracts automatically.

The heart also contains a group of specialized cells called the *sinoatrial node,* or *S-A node.* The S-A node starts up each contraction of the cardiac muscle by giving off rhythmic signals to neighboring muscle cells. As these cells contract, they cause others to contract as well. By this process, all the cardiac muscle cells contract together. The autonomic nerves that stimulate the S-A node control how often the cardiac muscle contracts. The S-A node thus acts as the heart's "pacemaker," because it determines how often the heart beats to pump blood through the body. For further information about the heart, its parts, and how they work, see **Heart.**

How muscles work

All muscles contract when they are stimulated. Scientists have done much research to determine how muscles contract and how they are stimulated.

How muscles contract. During the mid-1900's, the English scientist H. E. Huxley developed what has become the most widely accepted theory to explain how muscles contract. This theory, called the *sliding filament theory,* proposes that the muscle fiber's thick myosin filaments have numerous small projections. These projections, called *myosin cross-bridges,* spring away from the myosin filaments when the muscle fibers are stimulated. These cross-bridges attach themselves to the thin actin filaments that run parallel to the myosin filaments. The cross-bridges pull on the actin filaments, causing them to slide between the myosin filaments. As the actin filaments slide, they pull the ends of the muscle toward its middle, making the muscle fibers shorten.

In order for the myosin cross-bridges to work, the substance *adenosine triphosphate* (*ATP*) must be produced by muscle cells. ATP provides the energy to slide actin filaments. It is produced when oxygen in muscle fibers combines with chemicals from food. Each muscle fiber contains only a small amount of ATP. When muscles work hard, the body's ability to turn food and oxygen into energy increases to make the needed ATP.

How muscles are stimulated. Muscle cells are excitable because the membrane of each cell is electrically charged. Thus, a muscle cell is said to have *electric potential.* This electric potential results from the presence of sodium and potassium *ions* (electrically charged particles) on each side of the membrane. Potassium ions easily move through the membrane and accumulate in the cell. Sodium ions do not enter the cell as easily. In addition, the membrane has a special mechanism that pumps potassium into the cell and pumps sodium out. Consequently, the cell normally contains much potassium but little sodium.

Muscle cells are stimulated by nerves or by hormones, depending on the muscle involved. When the muscle cell is stimulated, its electric potential changes rapidly. The excited membrane allows sodium to rush into the cell and potassium to flow out. The sodium-potassium pumping mechanism quickly reverses this change, returning the cell to its normal condition.

The change in electric potential in the muscle cell triggers the release of calcium from storage areas inside the cell. The calcium then builds up in the cell and eventually causes the actin filaments to attract myosin cross-bridges and produce contraction. The cell relaxes when the level of calcium drops back to normal.

Disorders of the muscles

Muscles function through an amazing coordination of many elements. Occasionally, however, the normal operation of muscles is disturbed. For example, a person may experience painful cramps of certain skeletal muscles if he or she exercises too hard or for a long time. Skeletal muscle cramps involve *spastic* (sudden and violent) muscle contractions. No one knows exactly why such cramps occur. They probably result from having

too much or too little salt in the fluids surrounding muscle fibers. With proper rest and nutrition, the body can correct the problem, and cramping stops. Cramps also may develop in smooth muscle organs, such as the stomach and intestine. Doctors use heat, massage, and medicines in treating cramps. See **Cramp**.

Hard muscular work also may cause skeletal muscles to become sore. In severe cases, the soreness may last up to four days. The cause of muscle soreness is not completely understood, but it probably involves damage to muscle and connective tissue. With proper exercise, the muscles and body can adapt to strenuous muscle work and greatly reduce the risk of tissue damage.

Numerous diseases affect skeletal muscles. Two major classes of muscle diseases are *muscular atrophy diseases* and *myopathies.* Atrophy diseases attack and damage the nervous system, including nerves that stimulate muscles. As a result, muscles progressively shrink and become weak. Amyotrophic lateral sclerosis—also called ALS or Lou Gehrig's disease—is an example of an atrophy disease (see **Amyotrophic lateral sclerosis**). Muscular weakness also occurs in myopathies. In these diseases, weakness results because the muscle itself does not function properly. Certain myopathies, such as various *muscular dystrophies,* are characterized by gradual wasting away of skeletal muscles.

Muscles in other animals

All of the more advanced animals have some kind of muscle tissue. The muscles of human beings and of other animals have many similarities. For example, human beings and other *vertebrates* (animals with backbones) have three kinds of muscles—skeletal, smooth, and cardiac. Some *invertebrates* (animals without backbones), such as insects, have striated muscles. Other invertebrates, such as scallops and squids, have both striated and smooth muscles. In most cases, the muscles of other animals operate in much the same way as human muscles. However, the speed at which striated muscles contract varies widely among species. In general, contractions occur faster in a small animal, such as the rat, than in a large animal like the cow. Paul A. Molé

Muscle Shoals is an area of the Tennessee River Valley in northwestern Alabama. It is commonly referred to as *the Shoals.* The area was named for a section of shallow water and rocky rapids that presented a major obstacle to river navigation during the 1800's. The Shoals lie east of the cities of Florence, Tuscumbia, and Sheffield. The town of Muscle Shoals was developed at the west end of the rapids and became a city in 1923. Muscle Shoals is a leading music recording center and draws international recording artists.

The Tennessee Valley Authority, created by Congress in 1933, controls Wilson and Wheeler dams at Muscle Shoals (see **Tennessee Valley Authority**). Both dams form lakes that hold rainfall and provide hydroelectric power. Wheeler also controls floods. Two nitrate plants were completed at Muscle Shoals in 1918. They were built because it was feared World War I (1914-1918) might cut off nitrate from Chile. David C. Weaver

Muscular dystrophy, *DIHS truh fee,* is a name for certain types of serious muscle diseases. The disorders weaken *skeletal muscles*—that is, the muscles that hold the bones of the skeleton together and move the body. Therefore, muscular dystrophies seriously affect movement, posture, and breathing. Skeletal deformities are often associated with this group of diseases.

All types of muscular dystrophies are inherited. They are caused by a defect in one or more of the genes that control muscle structure and function. Some types are inherited as a *dominant gene abnormality,* while others are inherited as a *recessive gene abnormality* or an *X-linked* or *sex-linked recessive gene abnormality.* In an X-linked recessive gene abnormality, the gene is on the *X chromosome,* one of the pair of chromosomes that determine a person's sex.

In a dominant gene abnormality, a person who inherits the defective gene from either parent will develop the disease. In a recessive gene abnormality, a person must inherit the defective gene from both parents to develop the disease. In an X-linked recessive gene abnormality, women are not affected but may pass on the defective gene to their children. If they pass on the defective gene, generally only their sons will develop the disease because males have only one X chromosome. Females have two X chromosomes, one of which has a normal form of the same gene. The presence of the normal gene usually prevents the harmful gene on the other X chromosome from producing its effects.

Doctors have not yet found a cure for any of the muscular dystrophies. The four most common muscular dystrophies are *Duchenne, facioscapulohumeral, limb-girdle,* and *myotonic.*

Duchenne muscular dystrophy is the most common and most rapidly progressive of the childhood muscle diseases. In most cases, the first sign of the disease is difficulty in walking at an early age, from 2 to 6 years old. Later, the patients fall frequently and cannot run. Walking and standing become more difficult, and a wheelchair is needed by adolescence. The disease eventually affects most muscles of the body. Doctors use antibiotics and flu shots for lung complications and balanced nutrition for overall health in an effort to extend the life expectancy of the patients. In addition, stretching exercises and braces to reduce muscle shortening and joint deformities may also help to improve the patient's mobility. Duchenne dystrophy is inherited as an X-linked recessive gene abnormality. It usually affects only boys.

Scientists have identified the genes that cause Duchenne dystrophy. They also have discovered a protein called *dystrophin* whose absence in muscle tissues causes the disease. Researchers are attempting to improve muscle function in Duchenne patients with

treatments that introduce normal genes or muscle cells into the muscles. These treatments may increase production of dystrophin.

Facioscapulohumeral and limb-girdle muscular dystrophies are slowly progressive and usually become evident in adolescence or early adult life. They affect both men and women. Most patients have a nearly normal life expectancy, though with increasing disability. Facioscapulohumeral dystrophy primarily affects the muscles of the face, shoulder, and upper arm. It is inherited as a dominant gene abnormality. Limb-girdle dystrophy primarily affects the muscles of the arms, shoulders, legs, and hips. It is inherited as a recessive gene abnormality.

Myotonic muscular dystrophy is the most common adult dystrophy. But symptoms may appear at any age. The signs of the disease include *myotonia* (stiffness) and slowly progressive muscle weakness in the arms, hands, and fingers, as well as in the feet and lower legs. Along with the onset of stiffness and weakness, patients develop disorders of nonskeletal muscles, including eye cataracts, diabetes, and weakening of the heart muscle. This disease can affect both men and women. It is inherited as a dominant gene abnormality.

The gene that causes myotonic dystrophy lies on one chromosome of a pair designated as *chromosome 19.* In 1992, scientists reported that with each generation of inheritance, the gene can grow bigger, causing the disease to become increasingly severe.

Other muscular dystrophies include *Becker, congenital,* and *distal.* Becker is similar to but less severe than Duchenne dystrophy. Congenital dystrophy involves early weakness at birth. Distal dystrophy initially involves the small muscles of the hands and feet.

Michael S. Hudecki

Muscular system. See Muscle.

Muses, *MYOOZ ehz,* were nine goddesses of the arts and sciences in Greek and Roman mythology. In Greek mythology, they were the daughters of Zeus, the king of the gods; and Mnemosyne, the goddess of memory. Each Muse ruled over a certain art or science. Calliope was the Muse of epic poetry; Erato, love poetry; Euterpe, lyric poetry; Melpomene, tragedy; Thalia, comedy; Clio, history; Urania, astronomy; Polyhymnia, sacred song; and Terpsichore, dance.

The Greeks believed the Muses lived on Mount Olympus with their leader, the god Apollo. Like him, the Muses remained young and beautiful forever. They could see into the future, which few other gods could do. They also had the ability to banish all grief and sorrow. The Muses had pleasing, melodic voices and often sang as a chorus. Early Greek writers and artists called on the Muses for inspiration before beginning to work. Any one or all of the Muses could be asked for help, even though each governed a special art or science.

The Muses played an important part in Roman mythology, though the Roman worship of Muses was borrowed from the Greeks. The Romans believed that Jupiter, the king of their gods, was the father of the Muses.

Several words come from the Greek word *Mousa,* meaning *Muse.* They include *museum,* which originally meant *temple of the Muses;* and *music,* which meant *art of the Muses.* C. Scott Littleton

See also Mythology (picture: The Muses).

Museum is a place where a collection of objects illustrating science, art, history, or other subjects is kept and displayed. At various museums, visitors can learn how people lived and worked in early times, what makes a work of art a masterpiece, or how electricity works. Some people also consider the term *museum* to apply to such educational institutions as planetariums, botanical gardens, zoos, nature centers, and even libraries.

Museum of Science and Industry, Chicago (WORLD BOOK photo)

The Metropolitan Museum of Art, New York, Rogers Fund, 1932

Museums preserve many interesting and beautiful objects from the past. The exhibit on the left traces the development of aircraft and railroad equipment. The dining room on the right, designed by architect Robert Adam for a London house of the 1760's, is displayed in its original form.

J. M. Mejuto, FPG

Historic villages are reconstructions of towns from various periods in history. Old Sturbridge Village, *above,* in Massachusetts shows life in a New England community of the early 1800's.

A museum collects, cares for, and researches the objects it displays. It also keeps a *study collection* of undisplayed objects. These objects—sometimes called *artifacts*—are often studied by students and researchers.

Kinds of museums

There are three main kinds of museums: (1) art museums, (2) history museums, and (3) science museums.

Art museums preserve and exhibit paintings, sculpture, and other works of art. The collections of some art museums include work from many periods. Famous museums of this type include the Louvre in Paris and the Metropolitan Museum of Art in New York City.

Some museums specialize in artworks of one period. For example, the Museum of Modern Art in New York City displays works created since the late 1800's. Other museums exhibit only one type of art. The Museum of International Folk Art in Santa Fe, N. Mex., for example, specializes in folk art from around the world.

Many art museums also have special exhibits. They borrow works of art from individuals or other museums for such exhibits, which usually last several weeks.

History museums illustrate the life and events of the past. Their collections include documents, furniture, tools, and other materials. Many cities and states have historical societies that operate history museums. Most of these museums have exhibits on local history.

Other types of history museums include *living history museums.* Museums of this type include *living history farms, historic houses,* and *historic villages.* These museums show how people lived or worked during a certain period. On living history farms, workers demonstrate how crops were planted and harvested in earlier times. Historic houses, such as Mount Vernon, George Washington's home near Alexandria, Va., have been restored to their original condition and are open to the public. Williamsburg, a historic village in Virginia, has restored and reconstructed buildings that date from the 1700's. In this village, costumed interpreters demonstrate how early colonists performed such tasks as cooking, making shoes, and printing newspapers.

Science museums have exhibits on the natural sciences and technology. *Museums of natural history* exhibit displays of animals, fossils, plants, rocks, and other objects and organisms found in nature. Most of them, including the National Museum of Natural History in Washington, D.C., have exhibits on ecology and the evolution of human beings. Many museums of natural history have special exhibits on dinosaurs and other topics.

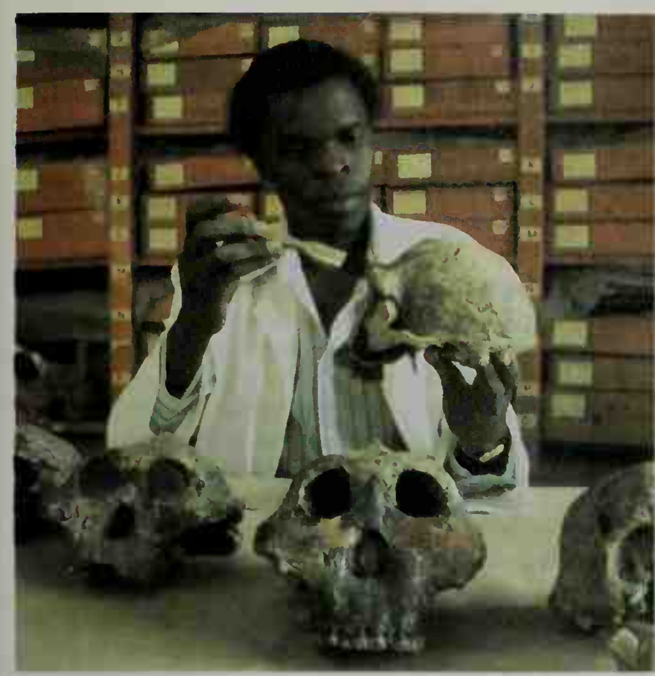
The exhibits in *science-technology museums* explain the operations of various types of machines and industrial methods or trace the development of a particular field of technology. Visitors to the Museum of Science and Industry in Chicago can take a guided tour through a realistic reproduction of a coal mine. The National Air and Space Museum in the Smithsonian Institution in Washington, D.C., has exhibits on the history of aviation and space travel.

Other types of museums feature exhibits on only one subject. The Circus World Museum in Baraboo, Wis., has the world's largest collection of circus wagons. The National Baseball Hall of Fame and Museum in Cooperstown, N.Y., shows highlights of baseball history and displays the uniforms of famous players. Other museums specialize in such subjects as automobiles, clocks, and dolls.

Museums that display materials from several fields of study are called *general museums. Children's* or *youth museums* have exhibits designed to explain the arts and sciences to young people.

A few museums display reproductions or copies of objects. For example, some historical museums have life-sized figures sculptured from wax or plastics. Most of these figures are realistic likenesses of important people in history. The figures are dressed in appropriate costumes and placed in lifelike settings.

Functions of museums



Museums perform three main functions. These institutions (1) acquire new materials, (2) exhibit and care for materials, and (3) provide various special services.

Acquisition of materials. Every new object that a museum adds to its collection is called an *acquisition.* Many acquisitions are gifts from people who collect such items as paintings, precious stones, or sculpture.

Sacramento History Museum

An electronic exhibit, such as the one shown above, may require the participation of museum visitors.

Odyssey Productions

Exhibits must be carefully prepared before being displayed. The anthropologist's assistant shown above is cleaning fossils at the National Museum of Kenya in Nairobi.

Other gifts include items that have been kept in a family for many generations, such as a quilt or a journal of an ancestor.

Sometimes a museum buys an item needed to fill a gap in one of its collections. Museum employees may find new materials on archaeological expeditions or field trips. Museums also borrow materials or entire exhibits from other museums. Acquisitions are received by the museum *registrar,* a staff member who records the description of each object. Every acquisition is photographed and given a number. Museum officials determine the value of each object and insure it for that amount.

Exhibition and care of materials. Various members of the museum staff prepare the materials for exhibition. The museum *curator* may conduct research to learn more about objects. Museum *conservators* clean, preserve, or restore objects before they are exhibited.

The curator decides how materials are displayed. For example, a new object may be added to an existing exhibit or become part of a special exhibit. It may be hung on a wall or placed in a case. *Designers* plan and create displays. They build cases and furniture for the displays and set up lights and electric wiring. *Preparators* create display backgrounds and prepare materials for exhibit. Every exhibit receives a label that gives visitors some information about it. Descriptions of all objects appear in the museum's catalog as well.

Museums also protect their exhibits from loss or damage. The doors and windows of many museums have alarms in addition to locks. Exhibit cases are locked, and some may be connected to alarms. Guards patrol museums. Museums may use special light bulbs and devices that control humidity and temperature to protect objects from environmental damage.

Special services. Many museums have an *education department* that gives lectures and classes on the museum's collection. Most museums offer gallery talks, guided tours, and other programs for children and adults. Other activities provided by museums include art festivals, concerts, and hobby workshops. Many museums publish bulletins and pamphlets that describe current and future exhibits. Museums also furnish scholars with research materials and the use of special laboratories and libraries. *Evaluation specialists* determine how well the museum meets the educational needs of the public. Some museums serve as places where local artists can exhibit their work.

History

The word *museum* comes from the Greek word *mouseion.* In ancient Greece, the mouseion was the temple of the *Muses,* the goddesses of arts and sciences. In the 200's B.C., the word was used for a library and research area in Alexandria, Egypt.

Early museums. Throughout history, churches have performed some of the functions of museums. Many worshipers enjoy viewing church furnishings and decorations, including paintings, sculpture, and other art.

During the A.D. 1400's and 1500's, European explorers brought back samples of animal and plant life from North and South America and eastern Asia. They also brought objects made by craftworkers of those regions. Many Europeans collected such materials. Some placed their collections in cabinets that lined the walls of long, narrow rooms called *galleries.* The collections themselves were called *cabinets.*

In the 1500's and 1600's, royal families hired famous artists and craftworkers to create luxurious art objects and furnishings. Today, the Uffizi Palace in Florence, Italy, and other museums own these collections.

The first public museum, the *Ashmolean,* opened in 1683 at Oxford University in England. The museum featured a collection of *curiosities* (rare or strange objects) donated by Elias Ashmole, an English scholar.

Museums of the 1700's. In the mid-1700's, a Swedish botanist named Carolus Linnaeus developed a system of classifying plants and animals. For many years, as a result of his work, scientists concentrated more on putting organisms into various groups than on acquiring new knowledge. Collections of scientific specimens were used mainly for classification purposes.

During the late 1700's, scholars began to study and organize large and complex collections of all kinds. Valuable works of art were separated from objects of little artistic worth. At about this time, people began to use the word *museum* to describe a place where collections could be seen and studied.

The demand for public museums grew in the 1700's, a period when people began to believe that education should be available to everyone. In 1759, the British Museum in London opened with exhibits of manuscripts, plant specimens, and curiosities. These materials had once belonged to the collections of kings and noblemen. In 1750, the Palais de Luxembourg was opened on certain days for the public to view the French royal art collection. During the French Revolution (1789-1799), the government moved the royal collection to the Louvre, which became a public museum in 1793.

Early United States museums. In 1773, the Charleston Library Society opened the first museum in the

American Colonies. It featured South Carolina's natural history. In the 1780's, Charles Willson Peale, a painter who studied natural history, opened a museum in his Philadelphia home. It displayed animal and mineral specimens and portraits of Thomas Jefferson, George Washington, and other Revolutionary War heroes.

In 1866, George Peabody, a Massachusetts banker, gave large sums of money to Harvard and Yale universities for the establishment of science museums. Many colleges and universities then began to use donations from wealthy people to establish museums.

By 1876, the United States had over 200 museums. In that year, the Centennial Exposition was held in Philadelphia. This world's fair included exhibits from various parts of the world. Its exhibits influenced the construction of an increasing number of museums.

Early Canadian museums. In 1842, Abraham Gesner, a geologist and inventor, founded Canada's first museum, the New Brunswick Museum, in Saint John, New Brunswick. It featured plants and animals, rocks and minerals, and Indian relics. Later in 1842, Sir William Logan, the director of the Geological Survey of Canada, started a natural science museum in Montreal. This museum eventually became the Canadian Museum of Nature and is now located in Ottawa. The Montreal Museum of Fine Arts, Canada's first art museum, was founded in 1860. It featured works by Canadian and other artists.

Museums today. Public interest in museums grew in the late 1900's, as many museums offered exhibits that appealed to large numbers of people rather than to specialized scholars. In the 1990's, many museums began using the Internet to exhibit materials to a worldwide audience. The Internet has also helped museums acquire materials, conduct research, and obtain funding.

Museums are funded by foundations and corporations; national, local, and state governments; and individuals. Some charge admission, sell reproductions or gifts relating to their exhibits, and offer food services, movies, or concerts for a fee. They also may earn money by selling less desirable items from their collections.

Careers

Most of the museum jobs described in this article require a college degree. Museums hire men and women with training in such fields as art history, history, and library science. The staffs of many museums also include archaeologists, botanists, geologists, zoologists, and other scientists. Many colleges and universities offer training in museum management and techniques. Many museums offer internships and work-study programs for students at the graduate and undergraduate levels.

Museum of African American History, in Detroit, is the world's largest institution dedicated to the culture of African Americans. The chief missions of the museum are to document and preserve the history and culture of African Americans through exhibitions, educational programs, and research. The full name of the museum is the Charles H. Wright Museum of African American History.

The museum has several exhibition areas, a research library, and a theater. One main exhibit, *Of the People: The African American Experience,* covers about 400 years of African American history and culture. There are thousands of artifacts and documents in the museum, including a collection on the underground railroad. The underground railroad was a secret system that helped slaves escape to the Northern States and Canada during the mid-1800's. Each year, the museum produces the African World Festival to showcase the culture of people of African descent who live outside Africa.

Charles H. Wright, a Detroit physician, founded the museum in 1965. Until 1987, it was called the International Afro-American Museum. Critically reviewed by the Charles H. Wright Museum of African American History

Museum of Modern Art, in New York City, is known throughout the world for its matchless overview of art from 1880 to the present. Its collections include more than 100,000 paintings, sculptures, drawings, prints, photographs, architectural models and plans, and design objects, ranging from audio equipment to textiles. In addition, the museum houses 10,000 motion pictures and 3 million movie *stills* (photographs).

The museum arranges special exhibitions that feature the work of specific artists, styles, or movements. Many of these exhibitions tour worldwide. The museum also shows films and publishes books and scholarly catalogs. Its library has over 80,000 books, periodicals, and catalogs, as well as an archive for research and reference.

The museum's original building, built in 1939, is one of the city's best examples of the International Style. It was designed by American architects Edward Durell Stone and Philip Goodwin. Architect Philip Johnson designed a remodeling and expansion in the 1950's and 1960's, and Cesar Pelli added a new wing in 1984. An expansion and renovation by Yoshio Taniguchi began in 2001 and was set for completion in 2005. The museum moved to a temporary site in Queens in 2002.

The museum was founded in 1929. It is a nonprofit educational institution supported by admission fees, memberships, contributions, and publication sales and services. Critically reviewed by the Museum of Modern Art

Museum of Science and Industry, in Chicago, is the largest and most popular science and technology museum in the United States. It is designed to further public understanding of science and the use of science in industry by presenting enlightening and entertaining

exhibits, educational programs, and other activities.

The museum opened in 1933 and now has over 600,000 square feet (56,000 square meters) of floor space. The museum's annual attendance of about $4 \frac{1}{2}$ million makes it one of Chicago's leading tourist attractions.

The museum focuses chiefly on the physical and life sciences, engineering, and mathematics. A large number of its exhibits demonstrate scientific and industrial advances and their applications for the present and the future. The museum emphasizes informal science education, and most of the exhibits are three-dimensional and encourage participation by visitors. For example, visitors may push a button to activate a demonstration or walk into a life-sized display. Visitors may also take a trip through a coal mine, go aboard a submarine, stroll a reconstructed street of 1910, and watch chicks hatch.

Many exhibits are presented as a public service by industrial firms, trade associations, professional societies, government agencies, and foundations. The museum staff develops other exhibits and activities.

The museum is housed in a restored classical style building from the World's Columbian Exposition of 1893. The major areas opened after restoration of the building was completed in 1940. The museum was founded largely through the efforts of Julius Rosenwald, a Chicago businessman and philanthropist. He contributed $3 million to help establish the museum.

Mushrooms have umbrella-shaped bodies.

Mushroom is any of a variety of fleshy, umbrella-shaped fungi. Mushrooms most commonly grow in woods and grassy areas. There are more than 5,000 *species* (kinds) of mushrooms worldwide.

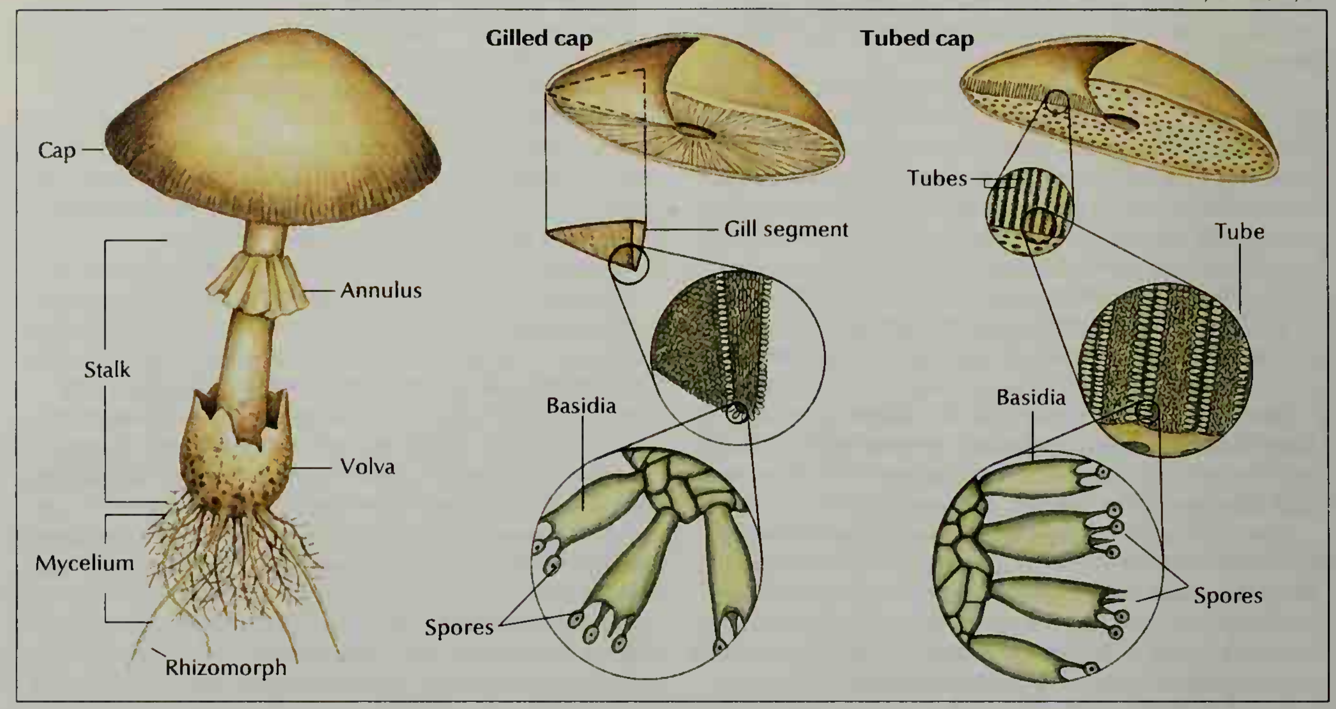
In the past, scientists considered mushrooms and other fungi as nongreen plants. Today, the fungi are most commonly regarded as a separate kingdom of living things. Like other fungi, mushrooms differ from green plants in that they lack *chlorophyll,* the green substance such plants use to make food. Instead, mushrooms survive mainly by absorbing food material from living or decaying plants, animals, or other fungi.

A mushroom consists of two main parts: (1) the mycelium and (2) the fruiting body. The mycelium typically grows in soil or wood and absorbs food materials. This part may live and grow many years. The umbrella-shaped fruiting body grows from the mycelium and commonly lives from one to several days. During that time, it produces tiny reproductive cells called *spores* from which new mushrooms grow. The fruiting body is the part most people consider the mushroom.

Mushrooms vary greatly in size and color. They measure from about $\frac{3}{4}$ inch (1.9 centimeters) to about 15 inches (38 centimeters) in height. The diameter of the top of a mushroom ranges from less than $\frac{1}{4}$ inch (0.6 centimeter) to about 18 inches (46 centimeters). Most mushrooms have a white, yellow, orange, red, or brown color. Some are blue, violet, green, or black.

Many species of mushrooms are tasty and safe to eat. But others have a bad taste, and some are poisonous. Certain poisonous species can prove fatal if eaten. Mushrooms that are either poisonous or have a bad taste are often referred to as *toadstools.*

Parts of a mushroom



The mycelium of a mushroom typically consists of numerous white or yellow, threadlike filaments called *hyphae.* The hyphae absorb food and water for the growth and development of the mycelium, and they eventually produce the mushroom's fruiting body. In most mushrooms, the filaments form a loose weblike mycelium. However, in some species they bundle together in long *rhizomorphs* (strands) that resemble shoelaces.

The fruiting body of the mushroom is made up of tightly woven filaments. It consists of a *stalk* topped by a rounded *cap.* Most species of mushrooms have thin, vertical, knifelike growths called *gills* on the underside of the cap. The gills spread outward from the center of the cap like the spokes of a wheel. Species without gills have densely packed, parallel *tubes,* or occasionally spines, under the cap. Tiny, club-shaped cells called *basidia* cover the outer surface of the gills or spines or the inner surface of the tubes. The basidia of most mushrooms produce four microscopic *spores.* The spores are reproductive cells from which new mycelia grow.

In some mushrooms, a clothlike membrane called a *partial veil* protects the gills or tubes as the mushroom develops. As the cap grows wider, the veil tears. It often remains draped around the stalk, forming a ring called an *annulus,* or it sometimes decorates the edge of the cap. In other species, a *universal veil* covers the entire immature mushroom. When the veil breaks, it leaves a *volva* (cup) or other remains at the base of the stalk. It also may leave warts or patches on the top of the cap.

Parts of a mushroom The drawing at the left, *below,* shows the chief parts of a mushroom. The other drawings show the details of the underside of the cap, which consists of either gills, *center,* or tubes, *right.* Tiny basidia on the gills or tubes produce the spores from which new mushrooms grow.

WORLD BOOK illustrations by Patricia J. Wynne

The life of a mushroom

How a mushroom obtains food. Mushrooms need carbohydrates, proteins, certain vitamins, and other nutrients. To obtain this food, the mycelium releases proteins called *enzymes* from its hyphae. The enzymes convert the materials on which the hyphae grow into simpler compounds that are absorbed by the mycelium.

Many species of mushrooms are *saprophytes*—that is, they live on dead or decaying materials. Some of these species obtain their food from dead grass or decaying plant matter, or from *humus* (soil formed from decaying plant and animal matter). Other species attack decaying wood, such as fallen trees, old stumps, and even the timber of houses. A few species live on the *dung* (solid body wastes) of animals that graze on grass.

Mushrooms called *parasites* grow on living plants, especially trees. A few of these mushrooms cause disease and may eventually kill the plants on which they feed.

Other mushrooms grow in or on roots of living green plants without causing harm. This type of association, called a *mycorrhiza,* benefits both the mushroom and the green plant. The mushroom's mycelium absorbs water, minerals, and other materials from the soil and passes these on to the plant. In turn, the plant provides carbohydrates and other materials for the mushroom. Mushrooms form mycorrhizae with a number of trees—including Douglas-fir, hemlocks, larches, oaks, pines, and poplars—and certain other plants.

How a mushroom grows. Typically, a mature mushroom releases millions of spores. The slightest air current can carry the spores away from the mushroom, sometimes to great distances. Often, however, only a few spores land in places with enough food and moisture for the spores to *germinate*—that is, to come out of dormancy and begin to grow. When a spore reaches such a place, it germinates by sending out one or more hyphae. Each hypha lengthens from its tip, branches out, and eventually may fuse and develop into a mycelium.

Knots about the size of a pinhead develop on the mycelium. These knots, called *buttons,* will become mature mushrooms. As a button grows, the cap and stalk become recognizable. Soon, either gills or tubes develop under the cap. Typically the stalk grows upward, and the cap enlarges and unfolds like the opening of an umbrella. Much of this growth results from the lengthening of cells as they absorb water. This is why mushrooms come up quickly, seemingly overnight, after a heavy rain. Most reach maximum height in about 8 to 48 hours.

The fruiting bodies die and decay after releasing their spores. But the mycelia often continue to live. In many cases, mycelia produce mushrooms for many years.

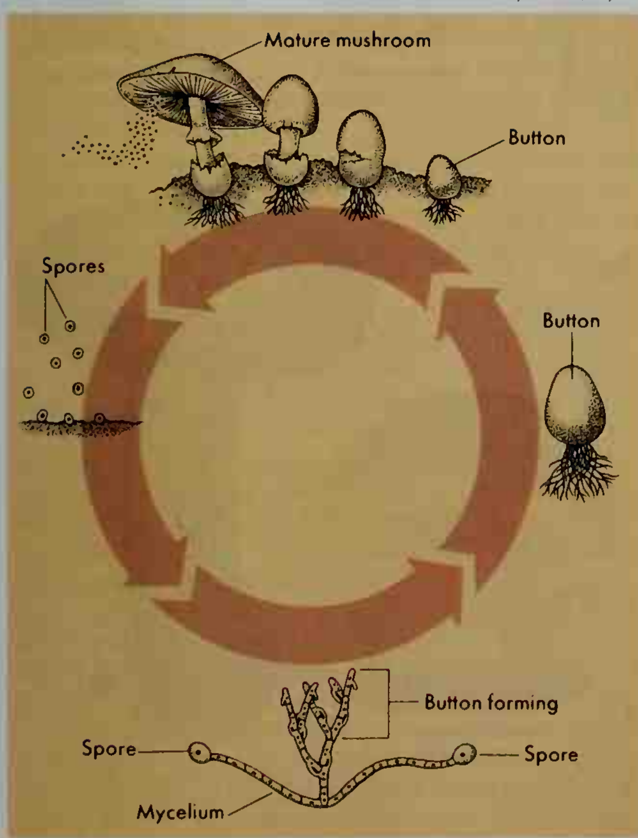
Fairy rings. In some areas, mushrooms grow along rings of grass or bare soil. Such rings are called *fairy rings.* People once believed that the rings were footprints left by fairies dancing at night. The mushrooms were thought to be seats on which the tired fairies sat.

Fairy rings develop in response to the growth of mycelia in the grass and soil. Mycelia tend to grow in all directions from a central point, forming an expanding circle. At the edge of the circle, nutrients released by the activity of the mycelia stimulate the growth of grass. As a result, the circle of grass directly above these mycelia may appear greener than its surroundings. Grass just inside the circle may die because growing mycelia absorb nutrients from surrounding soil. Fairy rings of bare soil may then appear near the circle's inner edge. If the soil remains undisturbed and nothing stops the mycelia's growth, fairy rings can become extremely large and last for many years. For example, some grasslands in Colorado have fairy rings about 200 feet (60 meters) in diameter. Scientists think these rings are over 300 years old.

S. Rannels, Grant Heilman

Joy Spurr

Mushrooms get food from the substances they grow on. Those in the top photo grow on dead wood, and those in the bottom photo on plant roots.



Kit Scates

A fairy ring of mushrooms grows in a field. It develops because the mushrooms' rootlike mycelia grow outward from a central point. The mushrooms that grow from these mycelia form an expanding circle.

How mushrooms reproduce

Mushrooms reproduce by releasing spores. A spore germinates and grows into branched, threadlike filaments that make up the *mycelium.* A knoblike *button* forms on the mycelium. It eventually develops a cap and stalk and becomes a mature mushroom.

WORLD BOOK illustration by Patricia J. Wynne

Kinds of mushrooms

Mushrooms belong to a scientific group called Basidiomycota. This group is divided into classes, orders, and families of mushrooms and other fungi according to common physical characteristics. *Mycologists* (scientists who study fungi) do not agree on the number of families of mushrooms. But most mycologists list mushrooms as *agarics* or *boletes.* Agarics have gills under their caps, and boletes have tubes.

In the following discussion, mushrooms are divided into two general groups: (1) poisonous and (2) nonpoisonous. There is no simple test to distinguish a nonpoisonous mushroom from a poisonous one. Therefore, people should not eat a wild mushroom unless they are absolutely certain that it is harmless.

Nonpoisonous mushrooms include more than 2,000 species. The best-known agaric of these species is the *table* or *button mushroom.* This good-tasting mushroom is available in supermarkets of many countries. When young, a table mushroom has a white or tan cap with pink gills. As the mushroom matures, the gills turn brown. A close relative of the table mushroom is the *field* or *meadow mushroom.* This species grows on lawns and meadows. It resembles the table mushroom.

Four other common agarics are the *fairy-ring mushroom,* the *oyster mushroom,* the *parasol mushroom,* and the *shiitake mushroom.* The fairy-ring mushroom grows in grassy areas, such as lawns and golf courses. It has a dull-yellow or tan cap with white gills. The oyster mushroom is one of the best-tasting wild mushrooms. It has a large, white to grayish-brown cap that resembles an oyster shell. Oyster mushrooms commonly grow in clusters on wood, especially logs and stumps. The parasol mushroom grows on the ground in woods. It has an

Some kinds of mushrooms

About 5,000 species of mushrooms grow worldwide. A number of them are illustrated here. They are divided into two groups: (1) agarics and (2) boletes. Agarics have gills under their caps, and boletes have tubes. The scientific name of each mushroom appears in italics.

Boletes

umbrella-shaped cap with brown scales on top, and a tall, slender stalk with an annulus. A shiitake mushroom grows on wood and has a brown cap with white gills. People commonly use it as food and in medicines.

The *inky caps* make up an unusual group of agarics. At maturity, their gills blacken and melt away drop by drop. People use the liquid as a substitute for ink. Inky caps grow in the spring, summer, or fall.

The *milky lactarius* are a group of colorful, summer agarics. A number of species from this group fruit in the summer. They all show drops of milky liquid when their gills or flesh are cut. The *indigo lactarius* has a beautiful blue stalk, cap, and gills.

Many boletes grow widely. The *old man of the woods* has a shaggy, scaly, grayish-black cap with grayish-white tubes. The *slippery Jack* possesses a slimy, reddish-brown cap. The *edible bolete* often has a fat, reddish-brown cap and a thick, white to brownish stalk. A fine netlike pattern may decorate the upper half of the stalk.

Poisonous mushrooms produce chemical compounds called *toxins.* Many toxic mushrooms are not fatal to people if eaten, but they may cause nausea, diarrhea, headaches, or other disorders.

A few mushroom species have deadly toxins. When a person eats these mushrooms, the symptoms of illness may not appear for several hours. The first symptoms include abdominal pain, violent vomiting, and weakness. Toxins of some deadly mushrooms damage the liver. Others attack the kidneys. In most cases, unless immediate medical treatment is given, the victim dies.

Some of the deadliest mushrooms belong to a group called the *amanitas.* These mushrooms have both a volva and an annulus. The *destroying angel* is an especially beautiful, all-white amanita that grows in the summer and fall. The toxins of the destroying angel have killed many people. Another amanita, the *fly agaric,* usually has a bright yellow, orange, or red cap with white warts on top. This species received its name from its use in killing flies. People sprinkled sugar on the mushroom to attract flies. The flies died after feeding on the mushroom.

The *jack-o'lantern mushroom* causes nausea and diarrhea if eaten. It tends to grow in clusters at the base of oak tree stumps. It has a bright orange cap and gills. The jack-o'lantern got its name because the cap and gills glow in the dark.

Mushroomlike fungi. Many large fungi resemble mushrooms but are not true mushrooms. The *bracket fungi* form shelflike growths on tree trunks. They commonly have tubes on the underside of their caps and often lack stalks. In general, bracket fungi have a tougher consistency than that of mushrooms. The *chanterelles* are mushroomlike fungi with funnel-shaped caps. The delicious and fragrant *golden chanterelle* is a delicacy prized by gourmets. The *puffballs* are ball-shaped fungi, white to tan in color. They range in size from smaller than a golf ball to larger than a basketball. When a puffball matures, its spores become dry and powdery. If touched, the puffball spores escape in a smokelike puff through an opening or pore.

Other mushroomlike fungi include *stinkhorns* and *morels.* Stinkhorns have a tall stalk capped with greenish slime that contains spores. These fungi smell like decaying flesh. Insects attracted to the odor eat the slime and then fly away to deposit the spores in other areas. Morels belong to a group of fungi called Ascomycetes, and they rank among the most flavorful fungi. They have a tan stalk and a darker, cone-shaped cap. The cap, covered with ridges and pits, resembles a sponge.

The importance of mushrooms

Mushrooms help keep soil fertile for the growth of plants. As mushrooms grow, they cause the decay of the materials from which they obtain food. This process releases important minerals into the soil. Plants use these minerals to grow and stay healthy. Today, people are trying to use mushrooms to help restore plant life in damaged natural environments.

Mushrooms are an important source of food for insects and many small animals. Red squirrels collect mushrooms in the summer and let them dry on tree branches. Then they store them for use as a winter food.

People eat mushrooms fresh in salads. They also use mushrooms to flavor eggs, meats, soups, and other food. Mushrooms provide a rich source of B vitamins and such minerals as potassium, phosphorus, and iron.

In addition, scientists are studying potential medicinal properties of mushrooms. Certain species may help prevent cancer, high blood pressure, and other diseases.

Mushroom cultivation ranks as an important industry in many countries. Most mushrooms are cultivated in specially designed buildings, where growers carefully control such conditions as temperature and moisture. Caves also provide ideal places for mushroom cultivation because of their consistently cool temperature and dampness. Since the late 1900's, many mushroom types, including shiitake and oyster mushrooms, have become more widely cultivated. Joe F. Ammirati

Scientific classification. Mushrooms are classified in the phylum Basidiomycota in the kingdom Fungi.

Musial, Stan (1920-), ranks as one of the greatest baseball players of all time. Nicknamed *Stan the Man,* Musial was a star outfielder and first baseman for the St. Louis Cardinals between 1941 and 1963. He won seven National League batting titles, and had a .331 lifetime batting average. Musial played in 3,026 National League games. Only Pete Rose and Henry Aaron played in more games in the league. Musial held the National League record for most base hits (3,630) until 1981, when the record was broken by Pete Rose.

Stanley Frank Musial was born on Nov. 21, 1920, in Donora, Pennsylvania. He was a vice president of the Cardinals from 1963 to 1991. He was elected to the National Baseball Hall of Fame in 1969.

A variety of musical performances, as shown above and on the next page, suggests some of the many forms of music. But whatever the form, all music is sound arranged for artistic effect.

Music

Music is sound arranged into pleasing or interesting patterns. It forms an important part of many cultural and social activities. People use music to express feelings and ideas. Music also serves to entertain and relax.

Music is a performing art. It differs from such arts as painting and poetry, in which artists create works and then display or publish them. Musical composers need musicians to interpret and perform their works, just as playwrights need actors to perform their plays. Thus, most musical performances are really partnerships between composers and performers.

Music also plays a major role in other arts. Opera combines singing and orchestra music with drama. Ballet and other forms of dancing need music to help the dancers with their steps. Motion pictures and TV dramas use music to help set the mood and emphasize the action. Also, composers have set many poems to music.

Music is one of the oldest arts. People probably started to sing as soon as language developed. Hunting tools struck together may have been the first musical instruments. By about 10,000 B.C., people had discovered how to make flutes out of hollow bones. Many ancient peoples, including the Egyptians, Chinese, and Babylonians, used music in court and religious ceremonies. The first written music dates from about 2500 B.C.

Today, music takes many forms around the world. The music of people in Europe and the Americas is known as *Western music.* There are two chief kinds of Western music, *classical* and *popular.* Classical music includes symphonies, operas, and ballets. Popular music includes country music, folk music, jazz, and rock music. The cultures of Africa and Asia have developed their own types of classical and popular music.

This article deals with the importance of music, musical instruments, the elements of music, and the system used for writing down music. It also includes information on the various types of Western and non-Western

music and on careers in music. For information about the history of Western music, see the *World Book* articles **Classical music** and **Popular music.**

The importance of music

Music plays an important part in all cultures. People use music (1) in ceremonies, (2) in work, and (3) in personal and social activities.

In ceremonies. Nearly all peoples use music in their religious services. One kind of religious music seeks to create a state of mystery and awe. For example, some cultures have special musical instruments played only by priests on important occasions, such as harvest ceremonies and the burials of chiefs. Similarly, much Western church music attempts to create a feeling of distance from the daily world. Other religious music helps produce a sense of participation among worshipers. The singing of hymns by a congregation is a good example of this function of religious music.

Many nonreligious ceremonies and spectacles also use music. They include sports events, graduations, circuses, parades, and the crownings of kings and queens.

In work. Before machines became important, people had to do much difficult or boring work by hand. Laborers sang songs to help make their work seem easier. For example, crews aboard sailing ships sang *chanteys,* songs with a strong, regular beat. The sailors pulled or lifted heavy loads in time to the beat. Today, the wide use of machines has made the singing of work songs rare in industrialized societies. However, many offices and factories provide background music for workers.

In personal and social activities. Many people perform music for their own satisfaction. Singing in a chorus or playing a musical instrument in a band can be very enjoyable. Music provides people with a way to express their feelings. A group of happy campers may sing cheerful songs as they sit around a campfire. A sad person may play a mournful tune on a guitar.

Many famous rulers have used music to help them relax. According to the Bible, David played the harp to help King Saul take his mind off the problems of ruling Israel. Kings Richard I and Henry VIII of England composed music. Other leaders have performed music. For example, Presidents Harry S. Truman and Richard M.

Nixon of the United States played the piano.

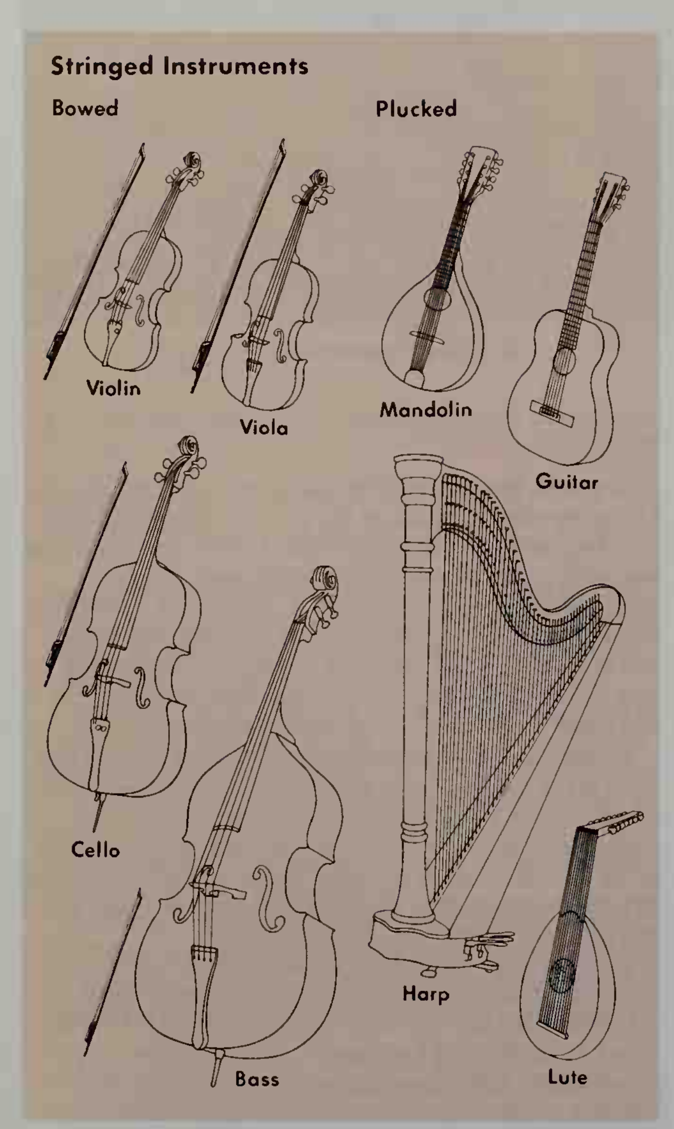
People use music at a variety of social occasions. At parties and dinners, music often is played for dancing or simply for listening. In some countries, a young man shows that a young woman is special to him by serenading her or by sending musicians to play and sing for her.

Musical instruments

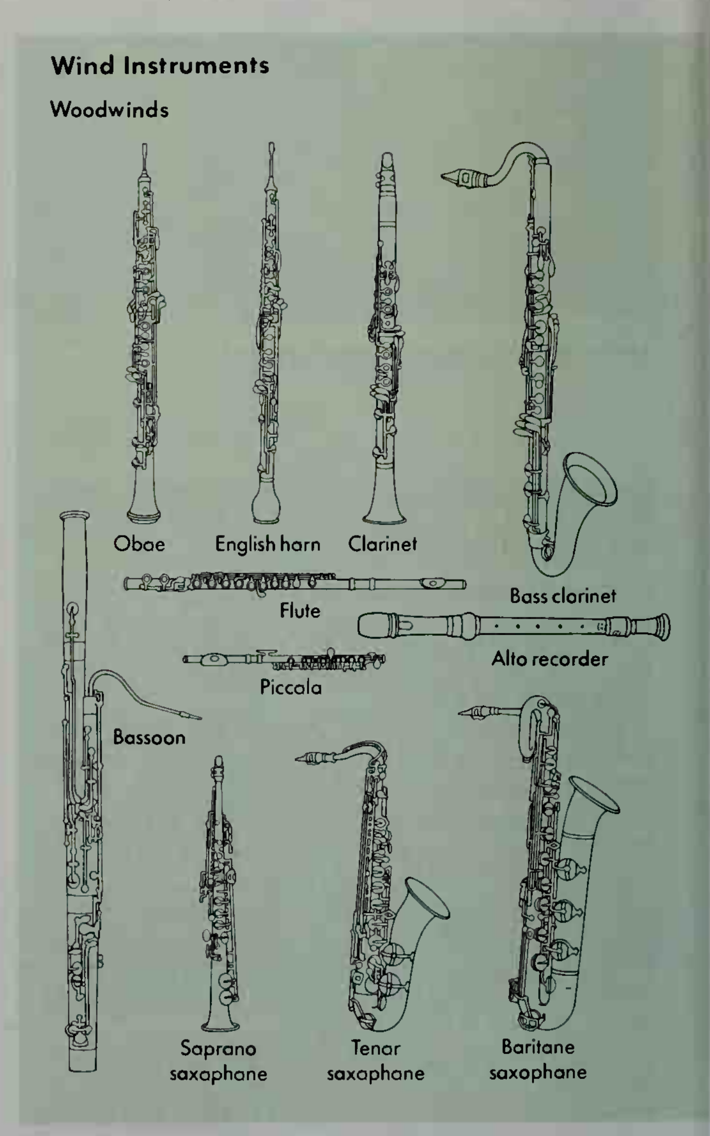
A musical sound, called a *tone,* is produced when air vibrates a certain number of times each second. These vibrations are called *sound waves.* Sound waves must be contained in some way so that the performer can control the pitch, loudness, duration, and quality of the tone. Whatever contains the sound waves must also provide *resonance*—that is, it must amplify and prolong the sound so the tone can be heard.

The vocal cords produce musical sounds in the human voice. These two small folds of tissue vibrate and create sound waves when air passes them from the lungs. The throat and the cavities in the head provide the resonance needed for singing.

Most musical instruments have a string, a *reed* (thin piece of wood or metal), or some other device that creates sound waves when set in motion. Musical instruments can be grouped in five major classes. These classes are (1) stringed instruments, (2) wind instruments, (3) percussion instruments, (4) keyboard instruments, and (5) electronic instruments.



Musical instruments have evolved throughout history. For example, 200 years ago, brass instruments did not have valves, and woodwind instruments had very few keys. Such features were added to modernize the instruments and to make them easier to play. As a result, the tone quality of the instruments also changed. In the late 1900's, many instruments were restored or built on original models so that the music of early composers can sound as originally intended.



Stringed instruments produce tones when the player makes one or more strings vibrate. There are two basic types of stringed instruments: (1) bowed stringed instruments and (2) plucked stringed instruments.

Bowed stringed instruments are played by drawing a bow back and forth across the strings. The pressure of the bow on the strings produces vibrations that are amplified by the body of the instrument. Most bowed instruments have four strings. Each of the strings is tuned

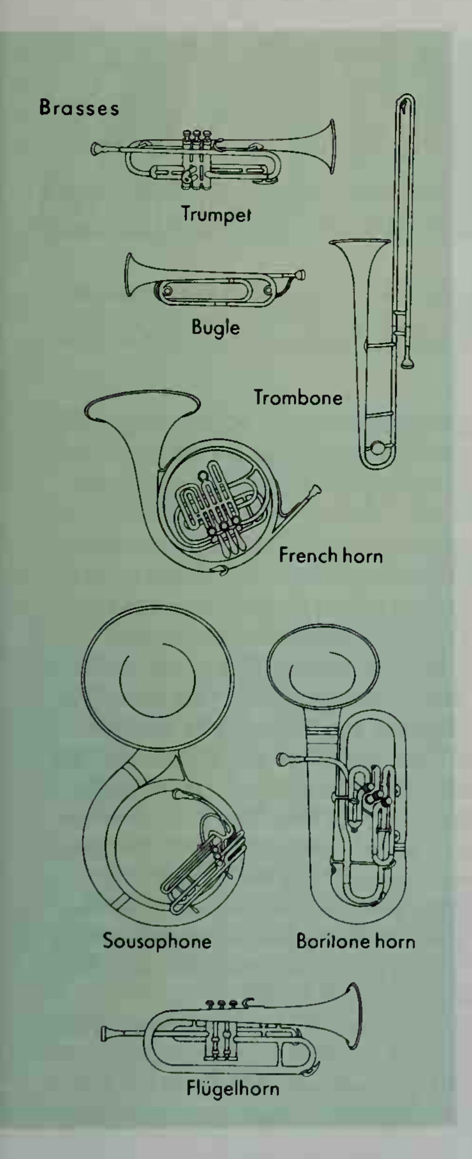
Musical instruments

The instruments shown here are grouped in four major classes: (1) stringed instruments, (2) wind instruments, (3) percussion instruments, and (4) keyboard instruments. The fifth major class of mu-

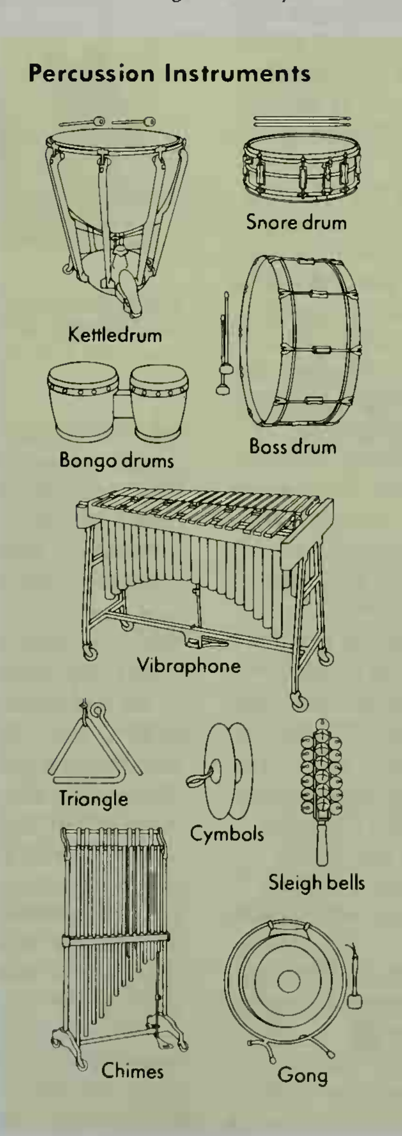
to a different pitch. To produce other pitches, the musician shortens the strings by pressing down on them with the fingers.

The main bowed instruments, in descending order of pitch and ascending order of size, are the violin, viola, violoncello or cello, and string bass. These instruments form the heart of a symphony orchestra. Violins in an orchestra are divided into *first violins* and *second violins.* The first violins play higher-pitched parts of musical compositions than the second violins.

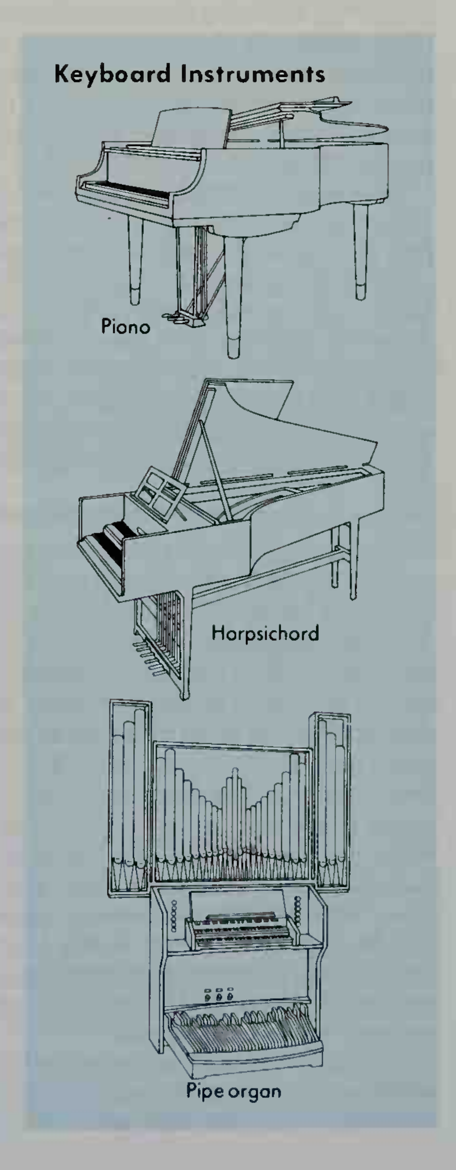
Plucked stringed instruments are played by plucking the strings with the fingers or a pick. The guitar is the most common plucked stringed instrument. It has 6 to 12 strings. The harp, another important plucked instrument, has up to 47 strings. It produces the most tones of any stringed instrument. Other plucked stringed instruments include the banjo, lute, lyre, mandolin, sitar, ukulele, and zither. The strings of the violin and other bowed instruments also may be plucked to produce special effects. This style of playing on a bowed instrument is called *pizzicato.*



Wind instruments are played by blowing into or through a tube. There are two chief types. They are (1) woodwind instruments and (2) brass instruments.



All woodwind instruments except the saxophone at one time were made of wood. Today, many are made of metal or other materials. In such woodwinds as recorders, the player blows through a mouthpiece into the instrument. In some other woodwinds, such as flutes and piccolos, the player blows across a hole in the instrument. Still other woodwinds, called *reed instruments,* have one or two reeds attached to the mouthpiece. The reeds vibrate when the musician blows on them. The clarinet and saxophone are the chief single-reed instruments. Double-reed instruments include the bassoon, English horn, and oboe.



The player controls the pitch by placing the fingers on holes in the instrument or on keys that cover holes. In this way, the player lengthens or shortens the column of air that vibrates inside the instrument. The piccolo and flute have the highest pitches of woodwinds, and the bassoon and contra bassoon, the lowest.

Brass instruments are played in a different way from that of woodwinds. The player presses the lips against the instrument's mouthpiece so that they vibrate like reeds when the player blows. By either tensing or relax-

sical instruments—electronic instruments—is not represented in these illustrations. Electronic instruments include electric guitars, electric pianos, electronic organs, and synthesizers.

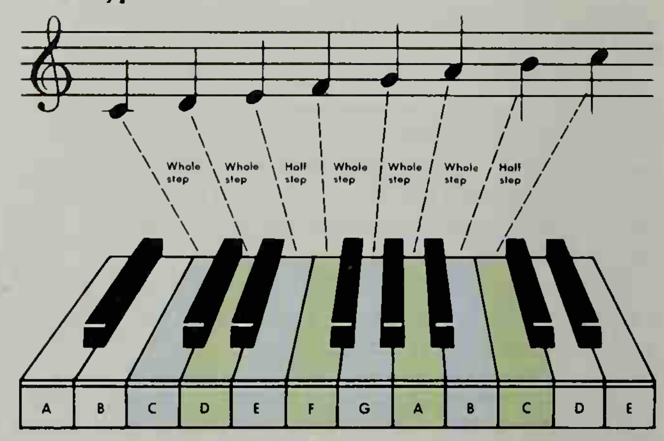
ing the lips, the player produces different pitches. With most brass instruments, the player can further control the pitch with valves that lengthen or shorten the tube through which the air is blown.

The chief brass instruments in an orchestra are the French horn, trumpet, trombone, and tuba. The French horn and trumpet have high pitches, and the trombone and tuba have lower pitches. The trombone has a slide instead of valves. The performer pulls the slide back and forth to control the pitch of the instrument. Other brass instruments, including the baritone horn and sousaphone, are used in bands.

Percussion instruments are sounded by shaking them or by hitting them with a stick or a mallet. Drums are the most common percussion instruments. Most Western drums do not produce a range of pitches. But kettledrums, also called *timpani,* can be tuned to various pitches by adjusting the tension of the drumheads. Glockenspiels and xylophones have a series of bars that produce a range of pitches. Other percussion instruments include castanets, cymbals, gongs, marimbas, and tambourines.

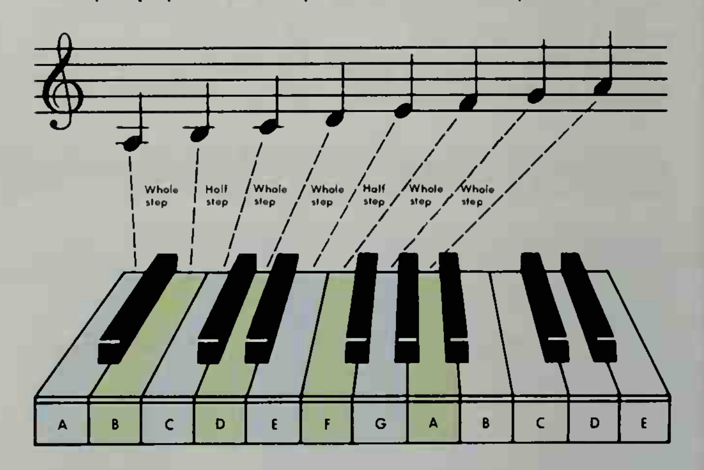
Keyboard instruments have a series of keys connected with a device that produces tones. The musician presses the keys to make sounds. The most popular keyboard instruments are the piano, harpsichord, and pipe organ. The keys on a piano activate small hammers that strike strings. On a harpsichord, the keys control a mechanism that plucks strings. Pressing a key on a pipe organ opens a pipe through which a column of air vibrates. The player operates some pipes by pressing pedals with the feet.

Electronic instruments include those that generate sounds by electricity and those that electronically amplify sounds produced by an instrument. The most common electronic instrument is the electric guitar. It makes louder and more varied tones than an ordinary guitar. Electric guitars, electric pianos, and electronic organs are widely used in rock music. An electronic instrument called a *synthesizer* is used to create original sounds or to imitate the sounds of other musical instruments. Some synthesizers are operated by computer.



The elements of music

A composer uses five basic elements to create a piece of music. These elements are (1) tone, (2) rhythm, (3) melody, (4) harmony, and (5) tone color.

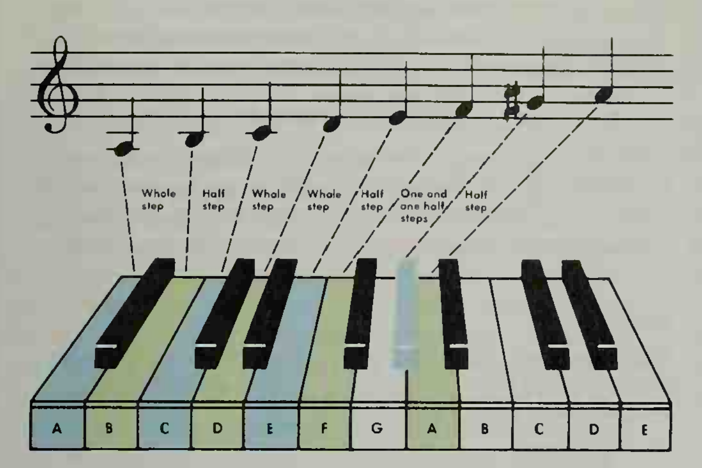


Tone is any musical sound of definite pitch. Most music is based on a *scale,* a particular set of tones arranged according to rising or falling pitch. Western musicians name the tones, or *notes,* of a scale with the first seven letters of the alphabet—A, B, C, D, E, F, and G. The letters are repeated every eight notes. The distance between a note and the next highest note with the same name, such as C to C, is called an *octave.* The higher note has twice as many vibrations per second as the lower note, and the two notes sound very similar. A note may be raised or lowered slightly in pitch to produce a tone halfway between it and the note next to it. The half tone above a note is called its *sharp,* and the half tone below a note is called its *flat.*

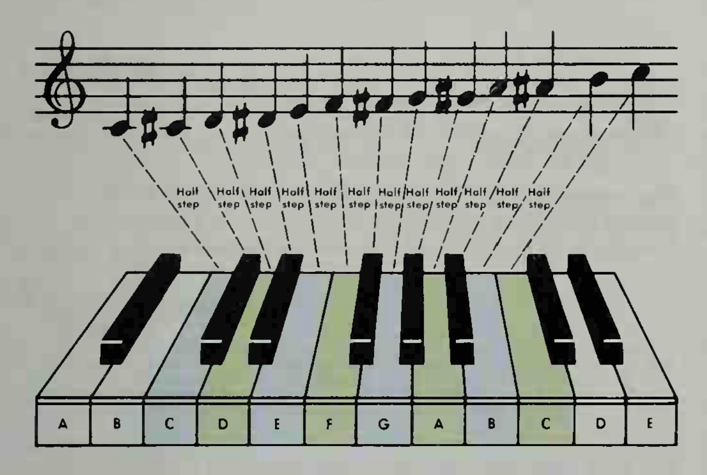
The notes in a scale are separated by *half steps* or *whole steps.* In Western music, a half step is the shortest distance between two notes. The distance between a

Some types of scales

The C major scale has a half step between its third and fourth notes and between its seventh and eighth notes. You hear it when you play the white keys from C to C on the piano.



The natural minor scale follows a pattern of one whole step, one half step, two whole steps, one half step, and two whole steps. This scale is often used in folk music.



note and its sharp or flat is a half step. A whole step equals two half steps—the distance from C to D or from D to E, for example. The steps in a scale are commonly called *degrees.*

Most Western composers have based their music on *diatonic scales.* A diatonic scale has eight notes to an octave arranged in a pattern of half steps and whole steps. There are two main types of diatonic scales, *major scales* and *minor scales.* The scales differ in the location of the half steps. A major scale has a half step between its third and fourth degrees and between its seventh and eighth degrees. Thus, the notes of a major scale are arranged in this order: two whole steps, one half step, three whole steps, and one half step. The *natural minor scale* follows a pattern of one whole step, one half step, two whole steps, one half step, and two whole steps. Two other minor scales, the *harmonic minor scale* and the *melodic minor scale,* follow other patterns of steps. However, all minor scales have a half step between the second and third degrees of the scale.

The notes of a diatonic scale vary in importance. The main note, called the *tonic,* is the first degree of the scale. The tonic serves as the tonal center of the scale, and all other notes are related in some way to the tonic.

The harmonic minor scale has one and one half steps between its sixth and seventh notes. This wide leap provides a bridge to the *tonic,* or main note, at the octave.

The chromatic scale consists entirely of half steps and has 12 notes to an octave. You hear this scale when you play all the white and black keys from C to C on the piano.

The tonic also gives the scale its name. For example, C is the tonic in the C major and C minor scales.

Next to the tonic, the most important notes of a scale are the fifth degree, called the *dominant,* and the fourth degree, called the *subdominant.* The seventh degree is called the *leading tone* because it leads to the tonic at the octave.

A *chromatic scale* consists entirely of half steps. It has 12 notes to an octave, rather than 8. You can hear the chromatic scale if you play all the white and black keys from one C to the next C on a piano. After 1850, composers increasingly used notes from the chromatic scale to make their music more colorful. During the 1920's, the Austrian composer Arnold Schoenberg developed a type of music based on this scale. This music, called *12-tone music,* has no tonal center.

Rhythm is the way the composer arranges notes in time. Every note has a certain duration as well as a definite pitch. Some notes may last a short time, and others a relatively long time. Rhythm helps give music its character. For example, a familiar piece of music sounds much different if the music is performed with all its notes the same length. The piece of music sounds strange because it lacks the variety of the short and long notes that make up its normal rhythm.

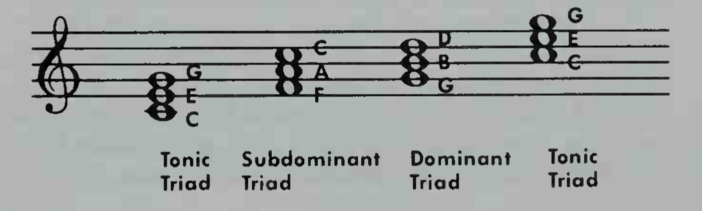
Another important element of rhythm is *accent.* Most composers build their music on a pattern of regularly occurring accents. Certain types of music have a fixed pattern of accent. For example, a waltz follows a strong-weak-weak pattern, *ONE two three ONE two three.* A march has a strong-weak pattern, *ONE two ONE two.*

Some composers create different rhythms by accenting beats that are normally unaccented. This technique, known as *syncopation,* has been widely used in jazz and ragtime music.

Melody. The composer combines pitches and rhythms to create a melody, or tune. The American composer Aaron Copland said, "Melody is what the piece is about." When we hear a piece of music, we most often remember its melody.

Some short pieces of music have only one melody. Longer pieces may consist of different melodies to give the music contrast and variety. A melody repeated throughout a composition is called a *theme.* Composers often use a part of a melody or theme to develop musical ideas. Such a part is called a *motive.* The first four notes of German composer Ludwig van Beethoven's fifth symphony form a motive. By repeating and varying these four notes, Beethoven developed a theme for the first part of this work that recurs through the entire symphony.

Harmony. Most Western music is based on the idea of sounding notes together. The sounding together of three or more notes is called *harmony.*



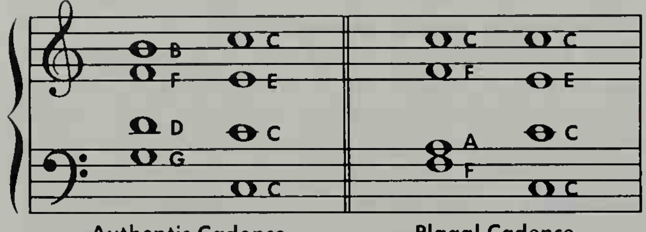
Harmony involves the use of various *intervals* (distances between notes) in a scale. Intervals are named according to the number of degrees they cover in a major scale. For example, an interval from A to C covers three degrees—A, B, and C—and is called a *third.* An interval spanning five degrees, such as A to E or C to G, is a *fifth.* Fourths, fifths, and eighths are called *perfect intervals.* Seconds, thirds, sixths, and sevenths can be either *major intervals* or *minor intervals.* Perfect intervals and major intervals can be *augmented* (raised a half step). Perfect intervals and minor intervals can be *diminished* (lowered a half step).

Composers use intervals to create *chords*—combinations of three or more notes sounded at the same time. Chords may be built on any note. The most common type of chord is the *triad,* which consists of three tones, each a third apart. For example, a chord that consists of the notes C, E, and G is a major triad. A chord with the notes C, E flat, and G is a minor triad.

The *tonic triad,* or *tonic chord,* is the most important

Triadic chords

Combinations of three or more notes are called *chords.* A *triad* is a chord made up of three notes, each a third apart, such as C, E, and G in a major scale. The most important triads in a musical composition are the *tonic, dominant,* and *subdominant.*



chord in a piece of music. It is built on the tonic note of the scale. The second most important chord is the *dominant chord,* and the third is the *subdominant chord.* The dominant chord is built on the fifth note of the scale, and the subdominant chord on the fourth. In the C major scale, the tonic chord is formed by C, E, and G; the dominant chord by G, B, and D; and the subdominant chord by F, A, and C. Any note in the diatonic scale can be harmonized with one of the chords—the tonic, dominant, or subdominant. Many simple songs are harmonized by using only these chords.

Most Western composers use a harmonic system based on the tonic and dominant tones of the scale. The composer fixes the tonic tone and thus a specific *key* (tonal center) firmly in the listener's mind. The composer may then *modulate* (shift) from one key to another by adding sharps or flats to the music. Generally, these sharps or flats prepare the dominant or tonic of the new key. Modulation adds variety and may emphasize a contrasting section of a work. In most cases, the composer eventually returns to the original key.

Another important element of harmony is *cadence.* Cadence is a succession of chords that end a musical work or one of its sections. Most pieces of classical music end with an *authentic cadence,* which consists of a dominant chord followed by a tonic chord. A *plagal*

Cadences

A series of chords that ends a piece of music is called the *cadence.* Most classical music ends with an *authentic cadence.* Many hymns use a *plagal cadence.* Examples appear below.

cadence consists of a subdominant chord followed by a tonic chord. The "Amen" ending of a hymn is an example of a plagal cadence.

Harmony has been a part of Western music for more than 1,000 years. However, Western composers' ideas about harmony have changed considerably over the centuries, particularly their ideas about *consonance* and *dissonance.* Harmony that sounds smooth and pleasant is consonant. Harmony that sounds rough and tense is dissonant. Generally, the notes that belong to the major and minor triads are considered consonant intervals, and all other intervals are dissonant.

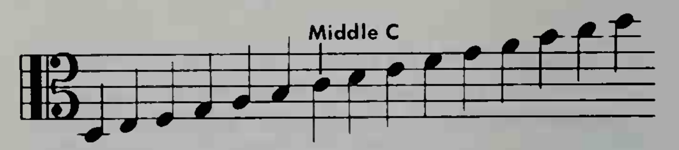
Composers use harmony chiefly for music that has a melody and accompaniment. Some musical compositions consist of two or more melodies played at the same time. This form of music is called *counterpoint.*

Tone color, also called *timbre,* is the quality of a musical sound. Tone colors produced by different musical instruments vary widely. For example, a melody that seems dark and mournful when played on the English horn may sound bright and merry when played on the flute. Composers take advantage of tone color in *orchestration* (writing or arranging music for a musical group). They combine tone colors much as an artist puts together colors in creating a painting.

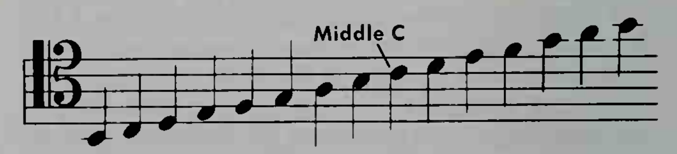
Musical notation

Through the years, composers developed a system for writing down music so it could be performed by musicians. This system is called *notation.* Notation indicates (1) the pitch of tones; (2) the time values, or duration of

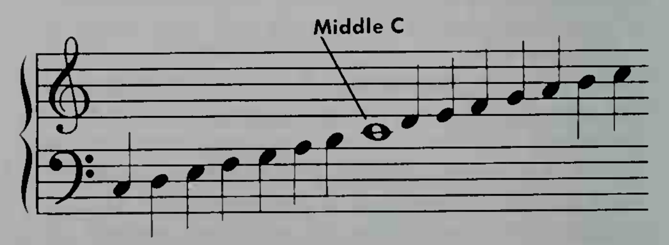
Pitch



Composers use a *staff* to indicate the pitch of notes. A *clef sign* determines the name of each line and space of the staff. The main kinds of clefs are shown below.



The treble clef, or *G clef,* fixes the G above *middle C* (the C nearest the middle of the piano keyboard) on the second line from the bottom of the staff. It is used for high notes.



The bass clef, also called the *F clef,* locates the F below middle C on the second line from the top of the staff. This clef is used in music that has low notes.

The C clef (alto) fixes middle C on the third line of the staff. It is chiefly used in music for the viola.

The C clef (tenor) locates middle C on the second line from the top of the staff. It is used for cello and bassoon music.

The grand staff combines the treble and bass clefs.

the tones; and (3) expression—that is, the composer's ideas about how the music should be performed.

Indicating pitch. Composers use *staff notation* to express pitch. In this system, sighs called *notes* represent tones. The notes appear on a *staff*, which consists of five horizontal lines and the four intervening spaces. Each line and space represents a certain pitch. Short *ledger lines* indicate pitches above or below the staff.

A *clef sign* at the left end of the staff determines the names of each line and space. Most music is written in either *treble clef* or *bass clef.* High notes, such as those for the violin and flute, appear in treble clef. This clef is often called the *G clef.* It fixes the G above *middle C* (the C nearest the middle of the piano keyboard) on the second line from the bottom of the staff. Lower notes appear in *bass clef,* also called *F clef.* The bass clef fixes the F below middle C on the second line from the top of the staff.

Composers use both treble clef and bass clef for piano and harp music. The *C clef* is used in music for the viola, and sometimes in music for the bassoon, cello, and trombone. This clef fixes middle C in a position that minimizes the number of ledger lines.

A *staff signature,* or *key signature,* appears at the right of the clef sign. It consists of sharp signs (♯) or flat signs (♭) that indicate which notes should always be played sharp or flat. Each staff signature can indicate either of two keys—one major key and one minor key. For example, two sharps can mean the key of either D major or B minor.

The composer may show a change from the staff signature by placing an *accidental* in front of a note. An accidental is the sign for a sharp, a flat, or a *natural* (♮). Any note not marked by a sharp or a flat is a natural. The natural sign cancels a sharp or a flat.

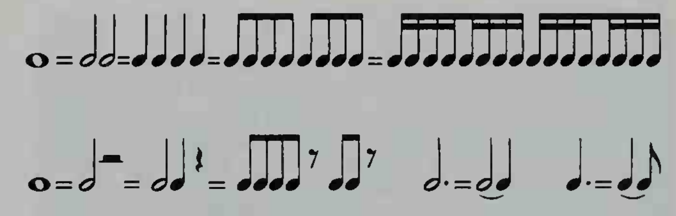
Indicating time values. Staff notation enables composers to indicate how long each note should be held. The *whole note* has the longest time value of any note. The second longest note is the *half note,* then the *quarter note,* the *eighth note,* the *sixteenth note,* the *thirty-second note,* and so on. Each time value is divided by two to find the next smallest note value.

The shape of a note shows its time value. Whole notes and half notes have an open oval shape. Notes with shorter values have solid oval shapes. All notes except whole notes have *stems.* To indicate notes with shorter values than the quarter note, composers attach *flags* to the stems. An eighth note has one flag; a sixteenth note, two flags; and a thirty-second note, three flags. In a series of short notes, the composer connects the note stems with *beams* instead of attaching a flag to each stem.

A dot at the right of a note increases its duration by

Staff signatures

The *staff signature,* or *key signature,* tells what key the music is written in. If the music has no flats or sharps, it may be in the key of C major or its *relative minor,* A minor. Each major key has a relative minor, and each minor key has a relative major.



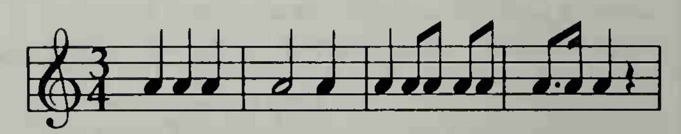
Time values

The shape of a note or rest indicates how long it lasts. The notes and rests shown below, from left to right, are whole, half, quarter, eighth, sixteenth, thirty-second, and sixty-fourth.

A whole note has the same time value as two half notes or four quarter notes or six eighth notes plus two eighth rests. A dot at the right of a note increases its time value by half. For example, a dotted half note equals a half note plus a quarter note.

half. For example, a dotted half note equals a half note plus a quarter note. Duration may also be increased by a *tie,* a curved line that connects consecutive notes of the same pitch. The total duration of tied notes equals that of the notes combined.

Periods of silence are an important part of a piece of music. The composer uses markings called *rests* to indicate silence in music. The various shapes of rests indicate their time values. A composer groups the notes and rests in a piece of music into units of time called *measures* or *bars.* The composer uses *bar lines* to separate measures on the staff. The way beats are grouped in measures is called the *meter.*



Meter is indicated by the *time signature,* a fraction that appears at the beginning of a piece of music. The numerator of the fraction tells the number of beats in a measure. The denominator tells what kind of note—half, quarter, or eighth—receives one beat. Music with a $\frac{2}{4}$ meter, for example, has two beats to a measure and a quarter note as the beat unit. One measure of $\frac{2}{4}$ may have a half note, two quarter notes, four eighth notes, or some other combination totaling two beats. A $\frac{4}{4}$ meter, sometimes written as *C,* has four quarter notes to a measure. Other commonly used meters are $\frac{3}{4}$ and $\frac{6}{8}$.

Many modern composers create irregular rhythms by changing the time signature several times during a piece of music. These composers also may use unusual time signatures, such as $\frac{5}{4}$ or $\frac{11}{16}$.

Time signatures

The *time signature* is a fraction that tells the number of beats in each measure and what kind of note receives one beat. For example, a signature of $\frac{4}{4}$ has four beats, and a time signature of $\frac{3}{4}$ has three. Both have a quarter note as the beat unit.

Musical terms

Accelerando, *ak* SEHL *uh RAHN doh* or *aht* CHAY *lay RAHN doh,* means gradually speeding up the tempo.
Accidentals are sharps, flats, and naturals not included in a key signature.
Adagio, *uh DAH joh* or *uh DAH zhee oh,* means slow.
Ad libitum, *ad LIHB uh tuhm,* indicates that the musician may play a composition with great freedom.
Agitato, AH *jee TAH toh,* means played in a restless or excited manner.
Allegro, *uh LAY groh* or *uh LEHG roh,* means fast and lively.
Andante, *ahn DAHN tay* or *an DAN tee,* means smooth and flowing, at a moderate speed.
Animato, AH *nee MAH toh,* means lively or animated.
Appassionato, *ahp* PAHS *syoh NAH toh,* means with great feeling.
Cadence, *KAY duhns,* is a series of chords that brings a composition or one of its sections to a conclusion.
Cantabile, *kahn TAH bee lay,* means songlike.
Chord is a combination of three or more tones played at the same time.
Clef is a sign that fixes the positions of notes on the lines and spaces of the staff.
Counterpoint is music that consists of two or more melodies played at the same time.
Crescendo, *kruh SHEHN doh,* means growing louder.
Decrescendo, DEE *kruh SHEHN doh* or DAY *kruh SHEHN doh,* means growing softer.
Diminuendo, *duh* MIHN *yu EHN doh,* means gradually growing softer.
Espressivo, EHS *preh SEE voh,* means with expression.
Flat is the half step below a given tone, with the same letter name as that tone. A flat is also the sign used to show that a tone should be lowered a half step.
Forte, *FAWR tay,* means loud.
Fortissimo, *fawr TIHS uh moh,* means very loud.
Interval is the distance between two notes. The interval consisting of the notes C and E is called a *third* because E is the third note of a diatonic scale from C to C. Likewise, C and F is a *fourth,* C and G a *fifth,* C to A a *sixth,* and so on.
Key is the particular scale used for a piece of music. It is based on a certain note, called the *tonic.*
Largo means extremely slow.
Ledger line is a short line drawn above or below the staff. It is used for notes too high or too low to appear on the staff.
Legato, *lih GAH toh,* means smoothly connected.
Maestoso, MAH *ehs TOH soh,* means majestic.
Measure is a unit of musical time containing an indicated number of beats.
Meter is the arrangement of beats in a piece of music. It is indicated by the *time signature,* a fraction that appears at the beginning of the piece.
Mezzo, *MEHT soh* or *MEHZ oh,* means medium. It modifies other terms, as in *mezzo forte* (moderately loud).
Moderato, MAHD *uh RAH toh,* means playing in moderate tempo.
Modulation, MAH *ju LAY shuhn,* is moving from one key to another key in a musical composition.
Molto, *MOHL toh,* means very or much. It modifies other terms, as in *molto allegro* (very fast).
Motive is a series of notes repeated throughout a piece of music.
Natural is a note that is neither sharp nor flat. A natural is also the sign used to cancel a preceding sharp or flat.
Octave is an interval of eight notes.
Pianissimo, PEE *uh NIHS uh moh,* means very soft.
Piano, *pee AH noh,* means soft.
Più, *pyoo,* means more. It modifies other terms, as in *più presto* (faster).
Prestissimo, *prehs TIHS uh moh,* means as fast as possible.
Presto means extremely fast.
Rallentando, RAHL *lehn TAHN doh,* or **Ritardando,** REE *tahr DAHN doh,* means gradually slowing the tempo.
Scale is a series of tones from one tone to its octave, arranged according to pitch.
Sforzando, *sfawr TSAHN doh,* means played with a sudden, strong accent.
Sharp is the half step above a given tone, with the same letter name as that tone. A sharp is also the sign used to show that a tone should be raised a half step.
Staccato, *stuh KAH toh,* means with distinct tones, sharply separated from one another. The tones are performed as rapidly as possible.
Staff consists of five horizontal lines and the spaces between them. Notes are written on the lines and spaces.
Tempo is the characteristic speed of a piece of music.
Theme is the main melody of a musical composition.
Tremolo, *TREHM uh loh,* means playing in a quivering or trembling style.
Vibrato, *vee BRAH toh,* means a slight wavering in pitch, occurring so quickly that it sounds like a single pitch.
Vivace, *vee VAH chay,* means played in a lively manner or with great speed.

Another important element of time in music is *tempo.* The tempo tells how slowly or quickly the beat unit should be played. Composers sometimes show tempo by a *metronome mark,* which indicates the number of beats per minute. The musician can then follow the tempo by using a *metronome,* a timekeeping machine that can be adjusted to tick off each beat. Composers also may use a number of Italian words to indicate tempo. For example, the word *adagio* means *slowly,* and the word *allegro* means *fast.* These Italian words are used because Italian musicians had the greatest influence in Europe during the 1600's and 1700's, when composers first used words to indicate tempo.

Indicating expression. To affect a listener's feelings, music must be expressive. Composers use various words and symbols to indicate the kind of expression they want in a piece of music.

Some directions indicate *articulation*—that is, how a series of notes should be connected. A curved line over or under notes means that the notes should be connected smoothly. This style of playing is called *legato.* A dot over or under notes indicates that they should be played as short notes with silence between them. Musicians call this type of articulation *staccato.*

Expression

Composers use words and symbols to show the kind of expression they want in music. For example, a curved line over notes indicates that the notes should be played *legato* (smoothly). A dot over notes means they should be played *staccato* (sharply separated).

Composers use certain Italian words or their abbreviations to indicate *dynamics* (loudness or softness). For example, the word *pianissimo* (or *pp*) means *very soft,* and the word *fortissimo* (or *ff*) means *very loud.* Other directions, also in Italian, concern the emotional quality of the music. For example, *dolce* means *sweetly,* and *cantabile* means *songlike.*

Music around the world

Western music is the music of people of European ancestry. It is the major form of music in Europe, North America, South America, and Australia. People in some Asian countries—for example, China, Korea, and Japan—also enjoy Western music. Western music can be divided into three main types: (1) classical music, (2) popular music, and (3) folk music.

Classical music, also called *art music,* is composed according to certain rules and performed by musicians from written music. It includes symphonies and music for opera and ballet.

Classical composers have written different styles of music during different periods of history. For example, most classical music composed in the late 1700's stresses simplicity and elegance. But much classical music of the late 1800's is highly imaginative and emotional. Music written by great classical composers of the past provides as much enjoyment today as when it was written. See **Classical music.**

Popular music includes many kinds of music, such as country music, jazz, rock music, and music from musical comedies and motion pictures. Popular music, or *entertainment music,* is generally much simpler than classical music. However, some pieces written as popular music hundreds of years ago are performed as classical music today. In addition, many great classical composers wrote some tunes in the style of the popular music of their time. Thus, the line between popular and classical music is flexible, not hard and fast.

Country music is derived from the folk music of rural whites of the Southern United States and other American traditional music. Country music is played from memory or *improvised* (spontaneously varied) from an existing song. See **Country music.**

Jazz first became popular about 1900 among blacks of the Southern United States. It combines the complex rhythms of African music and the harmony of Western music. Jazz musicians have experimented with many kinds of instruments and styles. Most jazz features much improvisation. See **Jazz.**

Rock music is a mixture of blues, country music, jazz, and American and British entertainment music. It is easier to understand than classical music or jazz. Styles of rock music frequently change, but such music always has a strong beat and a simple melody and rhythm. See **Rock music.**

Folk music consists of the traditional songs of a people. Most folk songs begin in rural communities. One person makes up a song, and other people hear it and learn to sing it. Some folk songs have been passed on in this way for hundreds of years. Many composers, including Edvard Grieg of Norway and Antonín Dvořák of Czechoslovakia, have used folk music in their works. See **Folk music.**

Asian music sounds different from Western music because the scales, instruments, and composing techniques used are different. For example, a scale in Western music has 12 steps to an octave. But the Arab scale

De Wys, Inc.

Bulgarian folk musicians and dancers perform a *dance song.* Dance songs are a type of folk music composed to accompany folk dances.

has 17 steps to an octave, and the Indian scale has 22 steps. Such scales are called *microtonal* because they are made up of *microtones*—that is, intervals smaller than a half step. The chief types of Asian music are those of (1) China, (2) Japan, (3) India, (4) the Arab countries, and (5) Indonesia.

Chinese music played a major role in ritual dances and songs at least 3,000 years ago. Orchestras with hundreds of musicians performed at early Chinese religious ceremonies and court festivities. Today, all Chinese plays are set to music. *Peking opera,* also called *Beijing opera,* is the most popular form of Chinese drama. It combines dialogue, music, dancing, and acrobatics.

Chinese musical instruments include the *qin* (ch'in) and the *pipa,* two plucked stringed instruments. Chinese musicians also play bowed stringed instruments, flutes, and percussion instruments, especially bells, drums, and gongs. The basic scale of Chinese music has five notes, most commonly F, G, A, C, and D. Traditional Chinese music has no harmony.

Japanese music was influenced by the court music of China. Japanese court music, called *gagaku,* dates from the A.D. 700's. Japanese orchestras consist of *shakuhachi* (bamboo flutes), gongs, drums, and such plucked stringed instruments as the *samisen* and the *koto.*

Music is an essential part of Japanese theater. The *no play,* a form of Japanese drama developed in the 1300's, features solo and choral singing with accompaniment by a small orchestra. A large orchestra provides background music for the *kabuki,* a dance-drama.

Japanese music has no harmony but makes use of microtones and free rhythm. The basic scales are the natural minor scale and a major scale with the fourth note raised a half step—for example, the C major scale with an F sharp instead of an F.

Indian music is one of the few kinds of non-Western music that have become internationally popular. It first flourished in Hindu temples and the courts of the *maharajahs* (great kings) of India. A soloist sings or plucks a stringed instrument, such as the *vina* or the *sitar.* The soloist may be accompanied by a drummer and a musician playing a *tambura,* a lutelike instrument.

The notes of the Indian scale are arranged in various patterns called *ragas.* Each raga has a special meaning and may be associated with a particular mood, emotion, season, or time of day. The performer chooses an appropriate raga, plays it, and then improvises on it.

Arab music is the music of the Arab nations of the Middle East and northern Africa. The main Arab instruments include flutes; drums; and two plucked stringed instruments, the *oud* and the *qanun.* Most Arab songs have instrumental accompaniment. However, musical instruments may not be used in Muslim worship. The chief Muslim religious music consists of calls to prayer sung by criers called *muezzins* and the chanting of passages from the Quran, the sacred book of the Muslims.

Indonesian music is noted for orchestras called *gamelans.* These orchestras consist of drums, gongs, and xylophones and are used to accompany puppet plays. Gamelan music has a kind of harmony because the instruments play different melodies at the same time.

African music is the music of black peoples who live south of the Sahara. These peoples use music in almost every aspect of their lives, especially religious ceremonies, festivals, and social rituals. Many Africans believe that music serves as a link with the spirit world.

Don Smetzer, Click/Chicago

Japanese music is often played on plucked stringed instruments called *kotos, above.* Other Japanese instruments include gongs, banjolike *samisens,* and *shakuhachi* (bamboo flutes).

Drums are the most important instruments in African music. Some drums are made of animal skins and may be played with the fingers. Others consist of hollow logs that the performer beats with sticks. African musicians also play flutes, xylophones, and stringed instruments. One kind of instrument, called the *sansa* or *mbira,* consists of a number of metal strips attached to a piece of wood. The musician plays the instrument by plucking the strips with the fingers or thumbs.

Most African music features complex rhythms. The musicians create these rhythms by combining different patterns of beats played on drums and iron bells or produced by handclapping. Some African songs have harmony. In many songs, a leader sings a phrase and then the chorus repeats the phrase or sings a refrain. Elements of African music appear in jazz, spirituals, and the popular music of Brazil and the Caribbean.

American Indian music is the traditional music of the Indians of North and South America. Much of it de-

veloped before Europeans arrived in the Americas.

American Indians almost always perform music as part of an activity. For example, music and dancing play an important part in Indian religious ceremonies and such tribal rituals as rain dances and hunting dances. Indian religious leaders called *medicine men* and *medicine women* sing songs as they treat the sick. The Indians also use songs in various social situations, such as courtship and trading. Many Indians compose their own songs. In the past, they said that they learned these songs from spirits that appeared to them in dreams.

Most American Indian music consists of singing accompanied by drums or rattles. Much of this vocal music uses a five-note scale—A, C, D, F, G. Some Indian groups also perform flute music. In parts of Latin America, the music of the Indians mixed with the folk music of their Spanish conquerors. This mixture produced distinctive types of popular music and dance.

John Running, Stock, Boston

American Indian music often features singing and dancing accompanied by rattles. American Indians almost always perform music as part of an activity, such as a religious ceremony.

Careers in music

Careers in music provide many personal rewards. But such careers require talent and dedication. Only a person willing to devote a great deal of time to study and practice should consider a career in music.

A young person interested in a musical career should start lessons in school and with a private teacher. After finishing high school, the student should enroll in a *conservatory* (specialized music school) or study music at a college or university. In addition to formal lessons, the student should practice and study independently.

Most people who study music want to become professional performers or composers. But competition is keen among musicians, and relatively few earn a living solely by performing or composing. Careers in popular music are difficult to achieve and offer little security. A rock group that suddenly becomes popular may fall out of favor just as quickly. Musicians perform in orchestras or in small groups that play in theaters, nightclubs, and television studios. A few with exceptional talent give solo recitals or perform as soloists with orchestras or opera companies. Composers may work as songwriters or arrange music for TV shows and commercials.

Teaching offers the largest number of career opportunities in music. Many composers and performers earn a living by teaching. Music teachers must have at least a bachelor's degree in music. Most college and university music teachers have a doctor's degree.

Other jobs in the field of music include positions as church organists or choir directors. Music critics review performances for newspapers or magazines. Specialists called *music therapists* work with patients in hospitals and nursing homes. These musicians use music to arouse feelings that help patients get better. Many people make, repair, or sell musical instruments. Large musical organizations, such as symphony orchestras and opera companies, employ concert managers, librarians, secretaries, and other workers. R. M. Longyear

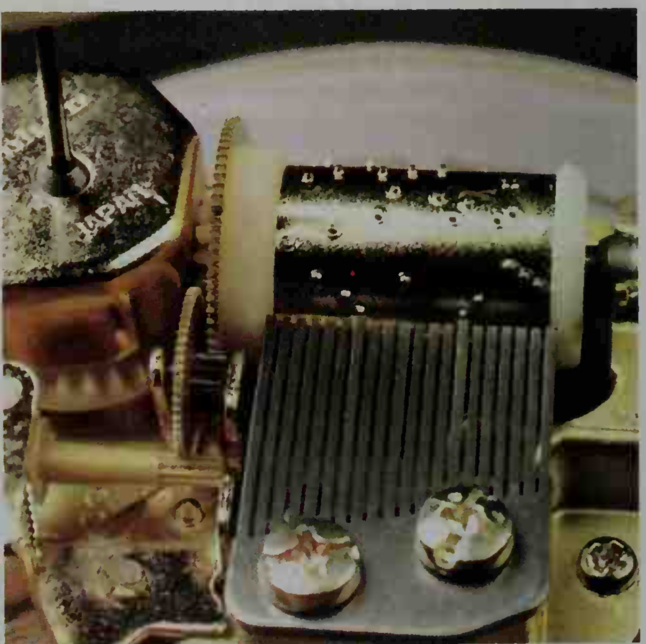
Music box is an instrument that plays tunes automatically. Steel pins protrude from a rotating cylinder driven by clockwork or a spring. The pins pluck metal teeth of various lengths, producing soft, high-pitched sounds of great delicacy. Several teeth may be tuned to the same note, so the box can repeat notes rapidly. Music boxes may be connected with clocks and play certain tunes on the hour. Music-box movements are built into watches, toys, and other everyday objects.

Early music boxes had tiny flute pipes instead of teeth and gave an organlike sound. Joseph Haydn wrote many charming pieces for the instrument. In the 1800's, some inventors developed music boxes that had as many as 400 teeth.

André P. Larson



Music Clubs, National Federation of, is the largest charitable music organization in the world. The federation is devoted to developing and maintaining high music standards in the United States and its possessions. The federation has about 600,000 members. People may join it as individuals or through music clubs, school clubs, choirs, choruses, conservatories, dance groups, or symphony orchestras.

The federation offers many awards and scholarships. Winners of the "Young Artist Auditions" receive $5,000 each. These awards are given every two years. The federation also sponsors "Cavalcade for Creative Youth" and the Victor Herbert-ASCAP Annual Awards in Composition for Juniors and Students.

The federation commissions works by American composers, and sponsors American Music Month and Parade of American Music in February and National Music Week in May. In addition, the federation publishes *Music Clubs Magazine* and *Junior Keynotes.* The National Federation of Music Clubs was founded in 1898. Its headquarters are in Indianapolis.

Critically reviewed by the National Federation of Music Clubs

Musical comedy is a type of play that tells a story through a combination of spoken dialogue, songs, and dances. Musical comedies are also called *musicals.*

Paul Robert Perry

A music box creates music mechanically. To produce notes, steel pins on a rotating cylinder pluck metal teeth of various lengths. A spring or clockwork mechanism drives the cylinder.

Most of them are light in tone and contain much humor. Musical comedies developed in the United States during the late 1800's and have become a unique American contribution to world theater. Many of the best-known songs in popular music originated in musical comedies.

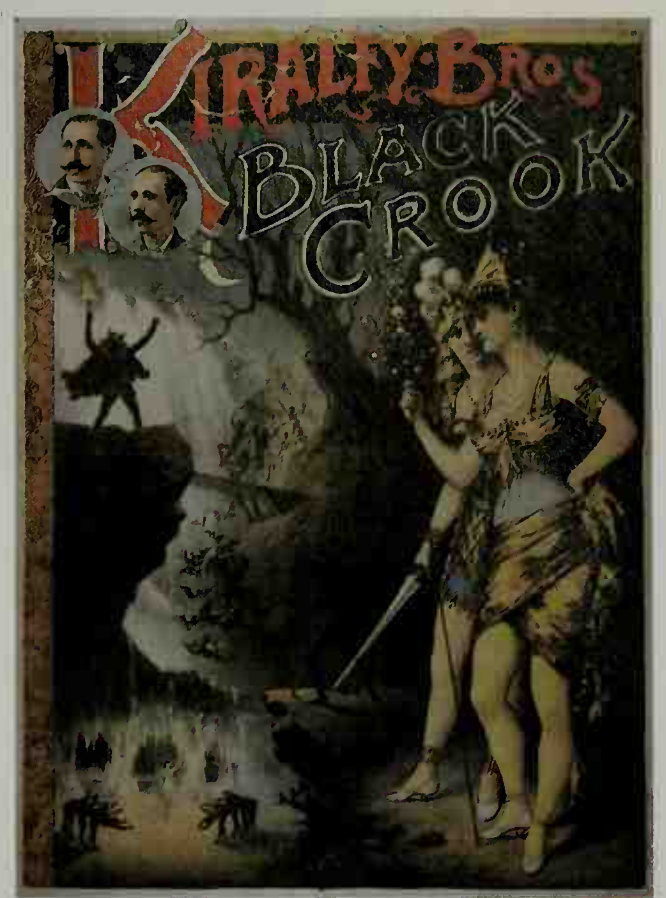
Musical comedy differs in several ways from other types of stage works that have music. For example, the *revue* has songs, dances, and skits but tells no story. The *opera* and *operetta* resemble musical comedy, but most of them have much less spoken dialogue. In addition, most operas use classical music, while nearly all musicals use popular music. Some plays may include songs or instrumental music, but the play remains dramatically complete without the music.

Most major American musical comedies are first presented in New York City, normally on Broadway. The more successful musicals later tour throughout the country and may even be performed in other countries.

Elements of musical comedy

A typical musical comedy consists of four basic elements. These elements are (1) the book, (2) the music, (3) the lyrics, and (4) dancing.

The book is the musical's story. It is sometimes called the *libretto.* The book provides shape and structure to a musical. A successful book integrates the dialogue, music, lyrics, and dancing. Some books are written specifically for a musical. Others are adaptations of other literary forms, especially novels, short stories, or plays. In some cases, the composer writes the book for a show, but most books are written by playwrights or other professional writers.



The music in a musical comedy may be vocal, instrumental, or both. In most shows, the music has a melodic form that the audience can easily remember. In the early history of musical comedy, the music served primarily to entertain audiences and show off the talents of the performers. But by the 1940's, the music began to serve a more dramatic function. Today, it is expected to help create characterization, advance the plot, and develop important situations or action. The composer works with the author of the book to determine where the music can most effectively be used in the story.

The lyrics may be written by the composer or by another person, called a *lyricist.* If the musical involves both a composer and a lyricist, the two must work closely together to ensure that the lyrics fit the music. In many songs, the lyrics contribute to telling the story or describing a character's feelings. The best lyrics are actually skillful poems set to music.

Dancing is one of the most distinctive elements of musical comedy. Some dances are meant only to entertain the audience. But many dances help tell the story or set a mood. Many shows employ a person called a *choreographer,* who creates dances especially for the show. In some cases, a show's director serves as the choreographer. Most dances in musical comedy are light and rhythmic, but some musicals include long dance pieces that resemble classical ballet.

The history of musical comedy

The first musicals. American musical comedy developed from a blend of American popular entertainment and the more classical elements of the European musical stage. The basic American influences were vaudeville, minstrel shows, and burlesques. All three types of entertainment had singing, dancing, and comedy, but none had a unifying story. European influences included the ballet, various forms of opera, and a form of elaborate spectacle called an *extravaganza.*

Billy Rose Theater Collection, The New York Public Library

The Black Crook is generally considered the first American musical comedy. It opened in 1866. The poster above reflects the show's emphasis on beautiful women and elaborate sets.

Most scholars believe that *The Black Crook* (1866) marked the beginning of American musical comedy. The show was noted for its spectacular scenery and emphasis on beautiful women. *The Black Crook* was based on European models. A truly American form of musical theater began to appear with *The Brook* (1879). This show included American themes and attempted to integrate the story with the songs and dances.

During the late 1800's and early 1900's, the European-style operetta was perhaps the most popular form of musical theater in America. Three European-born composers—Rudolf Friml, Victor Herbert, and Sigmund Romberg—were the most important composers of operetta in the United States.

A number of American composers and performers attempted to create a more American form of musical theater. In 1879, vaudeville stars Edward Harrigan and Tony Hart presented *The Mulligan Guards' Ball.* This show was the first in a series of *Mulligan Guards'* comic plays with music. The series dealt with recognizable American types and realistic scenes of everyday life. During the early 1900's, composer-actor George M. Cohan wrote the book, music, and lyrics for a number of high-spirited musicals. Such Cohan shows as *Little Johnny Jones*

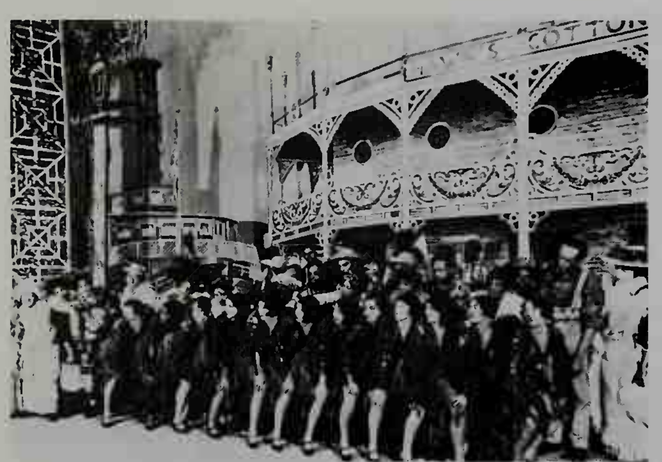
(1904) and *Forty-Five Minutes from Broadway* (1906) helped turn American musical comedy from European traditions toward a more native American style.

Musical comedy matures. During World War I (1914-1918) and the years soon afterward, American musical comedy took shape as a unique form of theater. Composer Jerome Kern ranks as probably the most influential figure in bringing musical comedy to maturity. From 1915 to 1918, Kern composed the music for a series of sophisticated musicals. Most of the shows had a book and lyrics by the English playwrights P. G. Wodehouse and Guy Bolton. These musicals were known as the "Princess shows" because they were presented in the Princess Theatre in New York City. The Princess shows had small casts and modern, everyday settings. The shows brought a natural, informal style to musicals.

In 1927, Kern and lyricist Oscar Hammerstein II completed *Show Boat,* a milestone in the development of musical comedy. *Show Boat* presented believable characters in a realistic manner and had a genuinely dramatic book. In addition, the show dealt with racial discrimination and other serious issues that were rarely mentioned in musicals of the time.

In 1931, a political satire called *Of Thee I Sing* opened in New York City. George Gershwin composed the music and his brother Ira wrote the lyrics. The noted playwright George S. Kaufman was coauthor of the book. The show became the first musical to win the Pulitzer Prize for drama. The award helped raise the status of musical comedy to the level of serious theater. The sharp attacks on American political life also broadened the range of subjects considered suitable for musicals.

A number of major composers and lyricists flourished during the 1920's and 1930's. Besides Gershwin and Kern, the leading composers included Irving Berlin, Cole Porter, Arthur Schwartz, and Vincent Youmans. The top lyricists included Howard Dietz, Ira Gershwin, Otto Harbach, and E. Y. Harburg. Composer Richard Rodgers and lyricist Lorenz Hart formed an outstanding partnership of the period. One of their best-known musicals, *Pal Joey* (1940), introduced a realistic, adult view of such themes as love and sex into musical comedy.



The modern musical emerges. The modern era of musical comedy began in 1943 with the premiere of *Oklahoma!* by Richard Rodgers and Oscar Hammerstein II. The show revolutionized musical comedy through its skillful integration of the story, music, and dancing. Rodgers and Hammerstein rapidly became the most popular team in the history of musical comedy. Their hits included *Carousel* (1945), *South Pacific* (1949), *The King and I* (1951), and *The Sound of Music* (1959).

A number of teams contributed popular musicals in the 1950's and 1960's. Composer Frederick Loewe and lyricist Alan Jay Lerner created *My Fair Lady* (1956). Composer Leonard Bernstein and lyricist Stephen Sondheim wrote *West Side Story* (1957), based on William Shakespeare's *Romeo and Juliet.* The show featured brilliant choreography by Jerome Robbins. Composer Jerry Bock and lyricist Sheldon Harnick collaborated on *Fiddler on the Roof* (1964). *A Chorus Line* (1975), one of the biggest hits in theater history, was created by choreographer Michael Bennett with music by Marvin Hamlisch. It dealt with the hopes and struggles of professional dancers as they audition for a new show.

During the late 1900's, musicals explored a wide range of subjects and styles. *Hair* (1967) dealt with young people of the 1960's who rebelled against society during the Vietnam War. *Grease* (1972) was a rock 'n' roll musical about high-school life during the 1950's.

Many critics consider Stephen Sondheim the most creative figure in musical comedy of his time. Sondheim began his career as a lyricist but soon began to write both the words and music. Sondheim gained praise for the wit and sophistication of his lyrics and for the originality of his subject matter. His best-known shows include *Company* (1970), *A Little Night Music* (1973), *Sweeney Todd* (1979), *Sunday in the Park with George* (1984), *Into the Woods* (1986), and *Passion* (1994).

The British composer Andrew Lloyd-Webber was probably the most commercially successful composer of his time. Lloyd-Webber was the key figure in the international success of British musicals since the early 1970's. His hits include *Jesus Christ Superstar* (1971), *Evita* (1978), *Cats* (1981), *Phantom of the Opera* (1986), and *Sunset Boulevard* (1994). In 1997, *Cats* became the longest running show in Broadway history. Such spectacular shows reflected a trend in musical theater of the late 1900's toward more lavish staging and settings. Mu-

Scene from the original production; Brown Brothers

Show Boat helped start a new era of musical comedy in 1927. The show had realistic characters and situations and introduced some of the most popular songs in musical comedy history.

Scene from the original production; Bettmann Archive

Oklahoma! began the age of the modern musical comedy in 1943. It revolutionized musicals through the way its dancing, songs, and dialogue combined to develop plot and characters.

The Lion King is based on a popular Walt Disney animated film released in 1994. The musical adaptation opened on Broadway in 1997 and became an immediate hit. The show imaginatively blends African masks and costumes with puppets, singing and dancing, and percussion instruments from many cultures.

Joan Marcus © Disney Enterprises, Inc.

sicals also moved away from the conventional book and adopted structures similar to the conventions of opera.

During the mid-1990's, more youthful subjects and modern rhythms or pop rock scores appeared in the hits *Bring in Da' Noise, Bring in Da' Funk* (1995) and *Rent* (1996). Old patterns remained, however, with the most successful musicals at the end of the 1900's being the spectacular *The Lion King* (1997) and *Ragtime* (1998).

Musical comedy today faces a crisis, in the opinion of many critics. Few original productions open, while imports and revivals dominate Broadway. The huge cost of staging musicals forces producers to select shows that will please large audiences. Small casts and modest productions rarely succeed. However, a number of new composers had emerged by the early 2000's, notably Jason Robert Brown, Ricky Ian Gordon, Adam Guettel, Michael John LaChiusa, Jeanine Tesori, and Frank Wildhorn. Don B. Wilmeth

Musicians, American Federation of, is a labor union affiliated with the American Federation of Labor and Congress of Industrial Organizations (AFL-CIO) and the Canadian Labour Council. Its official name is the American Federation of Musicians of the United States and Canada. It has local unions in the United States, Canada, and Puerto Rico. The union claims jurisdiction over almost all workers in the field of music, including performers, arrangers, conductors, and composers.

The American Federation of Musicians has reached many collective-bargaining agreements with such employers as recording companies, symphony orchestras, theatrical producers, and the motion-picture and television industries. These agreements set such employment conditions as wages, pensions, and health benefits.

The union was founded in 1896 in Indianapolis. It has headquarters in New York City. For membership, see **Labor movement** (table).

Critically reviewed by the American Federation of Musicians

Musil, *MOO sihl,* **Robert** (1880-1942), was an Austrian author best known for his long novel *The Man Without Qualities.* The first two volumes were published in 1930 and 1933. Musil died before completing the work. A fragment of the third volume was published in 1943.

The novel deals with both philosophical and political themes. The story takes place in Vienna in 1913 and concerns a man named Ulrich, who decides to become a "man without qualities." The character refuses to use his skills as an engineer and mathematician, and instead concentrates on seeking ethical and spiritual values. The novel describes the moral and political decline of Austria-Hungary. It also analyzes the cultural crisis in Europe that led to World War I (1914-1918), especially the difficulty of finding stable meaning in modern science.

Musil was born on Nov. 6, 1880, in Klagenfurt. His first major work was *The Confusions of Young Törless* (1906), a novel about adolescence. He also wrote essays and short stories, and two plays. Russell A. Berman

Musk is a raw material that is used in perfumes. It is formed in a gland in the abdomen of the male musk deer, an animal that lives high in central, eastern, and northeastern Asia. When the gland is dried, the musk forms into grains. The perfume ingredient is an oil that is removed from the grains with alcohol. People have hunted musk deer for their scent glands since ancient times. In 1934, scientists developed a synthetic form that has largely replaced natural musk. Patricia Ann Mullen

Musk deer is a type of small deer that roams the mountainous forests and brushlands of central, eastern, and northeastern Asia. The males use musk from a gland in their abdomen to mark their territories. The musk is highly prized for scenting perfumes and soaps. In some regions, musk deer have been hunted so extensively for their musk that they are nearly extinct.

Musk deer do not have antlers, but the upper canine teeth form small tusks. These deer stand from 20 to 24

Gerald Cubitt

The musk deer, *above,* has two upper teeth that form small tusks. Musk deer roam mountainous areas in many parts of Asia.

inches (51 to 61 centimeters) tall at the shoulders and about 2 inches (5 centimeters) higher at the rump. The hind legs are longer and heavier than the front legs. Musk deer have a thick layer of coarse, brittle hair that is yellowish-brown to dark brown at the surface and white at the base. The hair's color pattern helps camouflage the deer, and the thick coat protects the animal from the harsh weather found at high elevations.

Unlike most deer, musk deer generally live alone. They are most active at morning and evening, feeding on grass, lichens, roots, and twigs of shrubs. Musk deer mate in January, and the female bears a single spotted fawn about 160 days later. Gregory K. Snyder

Scientific classification. Musk deer form the subfamily Moschinae in the deer family, Cervidae.

Musk hog. See **Peccary**.

Musk ox is a large, hairy wild ox that lives in the cold Arctic plains. The musk ox's thick coat is its main defense against harsh Arctic weather. Its dark, shaggy overcoat has the longest hair of any mammal. A dense undercoat of extremely fine, soft hair also protects against cold and damp. Broad *cloven* (divided) hoofs help musk oxen scrape through snow to reach grass and other plants during the long Arctic winter.

Adult *bulls* (males) measure about 4 to 5 feet (1.2 to 1.5 meters) tall at the shoulders and weigh about 750 pounds (340 kilograms). *Cows* (females) are smaller. Both sexes have curving horns that meet on the forehead, but bulls' horns are larger. Bulls use their horns to fight each other during mating season. Cows usually give birth to one calf in May. Explorers once believed—mistakenly—that bulls secrete musk, a valuable ingredient in perfume.

Musk oxen are social, roaming in herds. When attacked by predators such as gray wolves, a group of 10 to 20 musk oxen forms a circle. The largest bulls and cows stand with their massive heads and sharp horns pointing outward, protecting the young in the center.

In the 1800's and early 1900's, people hunted musk oxen almost to extinction. In 1917, Canada enacted laws to protect these animals. Today, large herds roam again in Arctic Canada and Greenland. There are also smaller groups in Alaska and northern parts of Europe and Asia.
William L. Franklin

Scientific classification. The musk ox is in the family Bovidae. Its scientific name is *Ovibos moschatus.*

Muskellunge, *MUHS kuh luhnj,* is the largest fish of the pike family. It may reach a length of 6 feet (1.8 meters) and weigh about 100 pounds (45 kilograms). But most muskellunges are from $2\frac{1}{3}$ to 4 feet (0.7 to 1.2 meters) long and weigh 5 to 36 pounds (2 to 16 kilograms). The maximum life span of a muskellunge is about 25 years. The muskellunge looks much like the common pike. But, unlike the common pike, the muskellunge has no scales on the lower half of its head. Muskellunges may be brown, gray, green, or silver. Most have dark bars or spots on their side, but some are plain.

WORLD BOOK illustration by John F. Eggert

The muskellunge is a large North American pike.

The muskellunge lives in the lakes and quiet rivers of southern Canada. It also is found in the upper Mississippi Valley, the Great Lakes, and the St. Lawrence and Ohio rivers. Many people consider the muskellunge among the best of food fishes.

The "musky" is a prize among fishing enthusiasts. The fish is rarely found far from cover in the waters where it lives. Large adults feed on other large fish, ducks, muskrats, and other vertebrates. David W. Greenfield

Scientific classification. The muskellunge belongs to the pike family, Esocidae. Its scientific name is *Esox masquinongy.*

Musket was the firearm that infantry soldiers used before the perfection of the rifle. The name was first used in Italy in the 1500's to describe heavy handguns. It may have come from the Italian word *moschetto,* meaning *young sparrowhawk,* or from the name of an Italian inventor, Moschetta of Feltro.

A musket had a smooth *bore* (inside of the barrel). By contrast, a rifle bore has curved grooves.

Early muskets were 6 or 7 feet (1.8 to 2.1 meters) long and weighed as much as 40 pounds (18 kilograms). They fired either single round balls or round balls with smaller lead balls called *buckshot.* They were loaded from the muzzle. The first muskets were *matchlocks,* guns in which a cord match set off the powder charge. They were followed by *wheel locks,* in which a revolving wheel set off sparks; *flintlocks,* in which a flint struck a piece of steel to make sparks; and *caplocks,* in which an explosive cap set off the powder charge. Muskets were so inaccurate that it was difficult to hit a target more than 100 yards (91 meters) away. But the military

used muskets long after the development of the first accurate rifle in about 1655. Muskets were considered more convenient because a musket ball slid easily down the barrel. Rifle bullets had to be pounded down to fit into the grooves. Douglas M. Wicklund

Muskie, Edmund Sixtus (1914-1996), a Maine Democrat, served in the United States Senate from 1959 to 1980. He was the first Democrat ever elected to the Senate by Maine voters. He was the Democratic nominee for vice president of the United States in 1968. He and presidential candidate Hubert H. Humphrey were defeated by their Republican opponents, Richard M. Nixon and Spiro T. Agnew. In 1980 and 1981, Muskie served as secretary of state under President Jimmy Carter.

Muskie was born in Rumford, Maine. His father had changed the family name from Marciszewski. Muskie graduated from Bates College in 1936 and from Cornell University Law School in 1939. He served as a naval officer during World War II and became a member of the Maine House of Representatives in 1947. In 1954 and 1956, Muskie was elected governor of the heavily Republican state. As governor, he promoted education and control of water pollution. James I. Lengle

Muskmelon is the fruit of a type of plant that belongs to the gourd family. Muskmelons include cantaloupes, honeydew melons, and casabas. The melons vary in the color and texture of the rind and the color of the flesh. The flesh is eaten as a dessert or as a breakfast fruit.

The variety of muskmelon commonly known as cantaloupe in the United States has yellow-orange flesh and a yellow-brown rind covered with a tangle of ridges or netting. A ripe cantaloupe's flesh is sweet and has a musky odor. It is a good source of vitamins A and C. But scientists do not consider this melon to be a true cantaloupe. True cantaloupes grow in Europe. Their flesh is similar to that of those grown in the United States, but the rind is harder and warty and lacks the netting.

Honeydew melons have a smooth, green rind and green or white flesh. Casabas have a wrinkled rind. Like honeydew melons, casabas have green or white flesh. These melons do not have the musky odor of cantaloupe. All muskmelons have seeds that are attached to a netlike fiber in the center of the melon.

Muskmelons require a long growing season. They have the best flavor and sweetness when grown in a hot, dry climate. In the United States, high-quality melons can be grown in almost every state. In cool areas, growers plant seeds in greenhouses and later transplant them to the field after the last frost. Seeds are planted in warm soil in rows about 6 feet (180 centimeters) apart. The plants are later thinned to one plant about every 2 feet (60 centimeters).

Most muskmelons grow on vines that creep along the ground. The leaves have three to seven lobes. Blossoms open for only one day, and the flowers must be pollinated that day for the plant to bear fruit. Honey bees, which are attracted to the yellow blossoms, pollinate the plants. As a cantaloupe begins to ripen, the rind lightens in color and the fruit begins to *slip* (separate) from the stem. However, most honeydew and casaba melons do not slip from the stem. Fruit growers cut these melons from the vine and then store them until fully ripe.

WORLD BOOK illustration by Lorraine Epstein

The cantaloupe is a popular variety of muskmelon.

Scientists do not know for sure where muskmelons originally grew. However, many closely related plants originated in Africa and Asia, and many experts believe that muskmelons also originated there thousands of years ago. Muskmelons were introduced into Central America as early as 1516 and into the American Colonies by the early 1600's. Gary W. Elmstrom

See also **Casaba; Melon; Gourd.**

Scientific classification. Muskmelons belong to the gourd family, Cucurbitaceae. The scientific name for muskmelons is *Cucumis melo.* The cantaloupe of the United States is *C. melo,* variety *reticulatus.* Honeydew melons and casabas are *C. melo,* variety *inodorus.*

Muskoka Lakes, *muh SKOH kuh,* are a group of scenic lakes in the rocky uplands of southern Ontario. The swift-flowing Muskoka River drains the Muskoka Lakes into Georgian Bay. The lakes lie from 100 to 125 miles (160 to 200 kilometers) north of Toronto. Lake Muskoka, the largest of the group, covers 54 square miles (140 square kilometers). Lake Joseph, Lake of Bays, Rosseau Lake, and hundreds of smaller lakes lie nearby. Many streams and waterfalls are in the area.

The lake district is one of the most famous summer-resort regions in North America. Well-known resort centers include Bala, Baysville, Bracebridge, Dorset, Gravenhurst, and Port Sydney. The area has forests of balsam fir, pine, and spruce. Birch and maple trees add color to the region each autumn. George B. Priddle

Muskrat is an animal that lives near streams, ponds, and rivers. Muskrats get their name from the musklike odor they emit during the breeding season. They live in many parts of North America and have been introduced in some parts of Europe.

Muskrats are suited to life in the water. They use their scaly tails, which are flattened vertically, to help them swim and steer. Their hind feet are fringed with stiff, weblike hairs. Muskrats grow from 16 to 26 inches (41 to 66 centimeters) long, including a 10-inch (25-centimeter) tail. Their light-brown fur is sold as "Hudson seal" after the coarse *guard hairs* have been removed. Muskrat meat, properly prepared, is tasty and sometimes is sold as "marsh rabbit."

Leonard Lee Rue III, Bruce Coleman Ltd.

A muskrat lives near water and has a long tail.

Muskrats live in burrows that they dig in the banks of streams. They often damage dikes and levees as they dig. They also make winter houses by plastering such plants as cattails and reeds together with mud. These houses stand out on the icy, snow-covered marshes. Muskrat houses usually have more than one underwater entrance.

Muskrats eat vegetation, especially cattails, bulrushes, and the roots of water plants. They sometimes eat clams, crayfish, and snails. Minks, raccoons, coyotes, owls, hawks, and alligators prey on muskrats.

Female muskrats give birth to as many as three litters of 1 to 11 young each year. As a result, the muskrat population of an area often increases rapidly. Muskrats are born blind and nearly without fur. The furred young are often called *kits.* Muskrats fight a great deal among themselves. Many of them travel about—even as far as 20 miles (32 kilometers)—to find new homes.

Muskrats are rodents. They are related to lemmings and voles but are larger than these animals. A small, round-tailed muskrat inhabits Florida. Charles A. Long

Scientific classification. Muskrats belong to the subfamily Microtinae of the mouse and rat family, Cricetidae. The muskrat is classified as *Ondatra zibethicus.*

Musky. See **Muskellunge.**

Muslim Brotherhood is one of the most influential political and religious movements in the Middle East. The brotherhood calls for Muslim nations to establish governments based on Islamic principles. It rejects such Western ideas as capitalism and *secularism*—that is, the separation of politics from religion. The Muslim Brotherhood is known in Arabic as the Ikhwan al-Muslimin.

Hasan al-Banna, an Egyptian teacher, founded the brotherhood in 1928. He hoped to revive Islamic ideals as a basis for reorganizing social life and developing modern Egypt. By 1939, the movement had become increasingly political and had spread throughout North Africa and into Palestine, Lebanon, and Syria.

During the 1940's, some brotherhood members began to call for a more militant approach to establishing Islamic governments. In 1948, the brotherhood was implicated in the assassination of Egyptian Prime Minister Mahmud Nuqrashi, who had banned the movement. In 1954, the brotherhood was implicated in an assassination attempt against Egyptian leader Gamal Abdel Nasser. It then became mainly an underground movement.

In 1980, Syria made membership in the brotherhood a crime punishable by death. In February 1982, Syrian troops reportedly killed at least 10,000 people when they quashed an uprising of the brotherhood in Hama, Syria.

Some Arab governments eased control over the Muslim Brotherhood during the 1970's and 1980's. For example, brotherhood members in Egypt and Jordan were allowed a limited role in political life. Egyptian authorities remained suspicious, however, of the movement's aims and its continued popularity. They again moved to curb its activities during the 1990's. Christine Moss Helms

Muslims, *MUHZ luhmz,* sometimes spelled *Moslems,* are people who practice the religion of Islam. The Prophet Muhammad first preached the religion in the A.D. 600's. Islam originated with the Arabs in the Middle East. By the mid-700's, Muslims had built an empire that stretched from the Atlantic Ocean to the borders of China.

This article traces the history of the Muslim people throughout the world. For additional information about the religion of the Muslims, see **Islam.**

Before Muhammad

Abraham and Ishmael. According to Muslim tradition, the history of the Muslims begins with the story of Abraham and Ishmael. Both Jews and Arabs regard Abraham, who may have lived between about 1800 and 1500 B.C., as the father of their people. Abraham's wife Sarah was past childbearing age, so she gave her handmaiden Hagar to her husband as a second wife. Hagar bore a son, the prophet Ishmael. Later, Sarah and Abraham also had a son, the prophet Isaac. After Isaac's birth, Sarah pressured Abraham into expelling Hagar and Ishmael from his house.

Muslim tradition teaches that Hagar and Ishmael traveled to a valley in western Arabia called Bakka, which is now the city of Mecca. There they found a sacred well, called Zamzam, that sustained Hagar and Ishmael with its water. When Ishmael reached adulthood, Abraham visited him. Near the well of Zamzam, the two prophets built the Kaaba as a temple to God (Allah). In the eastern corner of the Kaaba, they placed the Black Stone, which Muslims believe was brought to them by an angel. The Kaaba became the holiest shrine of Islam. Muslims who perform the pilgrimage to Mecca walk around the Kaaba seven times. Many of them will try to kiss or touch the Black Stone.

The Arabs before Islam included nomads, traders, farmers, and town-dwellers. They belonged to many tribes and had many religions. Most Arabs worshiped multiple gods. Arab deities included the goddesses al-Lat, al-Uzza, and Manat, who were important in the Mecca region. The supreme deity of the Arabs was a remote heavenly god, whom they called Allah, which means "the god." The Arabs believed he was the creator of the universe, the bringer of life and rain. He was the god on whom people called in times of great danger or distress.

Muhammad

The Prophet Muhammad was born in Mecca in about A.D. 570. At that time, Mecca was a major commercial center controlled by an Arab tribe called the Quraysh

---

Vincent J. Cornell is Associate Professor of Religion at Duke University.

(pronounced *koo RAYSH),* who had abandoned the traditional Arab nomadic way of life and become merchants. The Quraysh were divided into clans, including the Banu Umayya *(BA noo oo MAY ah)* and the Banu Hashim *(BA noo HA shihm).* The Banu Umayya were the wealthiest and most powerful clan in Mecca. The Banu Hashim, into which Muhammad was born, were responsible for supplying food and drink for pilgrims who came to Mecca to visit the Kaaba.

In about A.D. 610, Muhammad began to receive revelations from Allah. For Muslims, the greatest miracle of Muhammad's prophethood was the Qur'ān *(ku RAHN),* sometimes spelled Koran, the holy book of Allah's revelations. The revelation of the Qur'ān to Muhammad took place over a period of about 22 years. Muhammad dictated the verses to his followers, who wrote them down. Several of these "Scribes of Revelation," such as Ali, Uthman *(ooth MAN),* and Muawiya *(moo AH wih yah),* became important Muslim leaders.

Several years after Muhammad's death, when Uthman was *caliph* (leader) of the Muslims, he formed a committee to collect these revelations into a single volume. Their work produced a master copy of the Qur'ān that became the model for the book used by Muslims today.

The people of Mecca persecuted the early Muslims because Muhammad had rejected their gods and because he condemned wealthy Meccans for not helping those in need, such as widows, orphans, and the poor. Eventually, Muhammad and his followers were forced to abandon Mecca.

In 622, a delegation from Medina, a town then called Yathrib which is north of Mecca, invited him to act as *arbitrator* (judge) between its feuding tribes. Muhammad's journey from Mecca to Medina is called the *Hijra,* also spelled *Hegira.* Muslims consider it so important that the Islamic calendar begins with the year of the Hijra. In Medina, Muhammad and his companions laid the foundations of Islamic society, which was based on the *Sunna* and the *Sharī'a,* also spelled *Sharī'ah.* The Sunna was the example of the Prophet's sayings and behavior. The Sharī'a was the code of Islamic law.

To defend Islam from its enemies, Muhammad launched several military campaigns against Mecca and other parts of the Arabian Peninsula. Mecca surrendered to him in 630. In 631, delegations from many tribes and clans in Arabia swore to give up the worship of multiple gods and submit to Muhammad's authority. In 632, Muhammad died in Medina.

The early caliphs

After the Prophet died, a dispute arose over his successor. On one side were members of the tribes of Medina, who wanted one of their own leaders to rule the town again. Another side included Muhammad's friend Abu Bakr, along with Umar, one of the most powerful of the early Muslims. After the death of his first wife, Muhammad had married both Abu Bakr's daughter Aisha *(ah YEE shah)* and Umar's daughter Hafsa. They were the most influential of the Prophet's wives. In addition, some Muslims thought Muhammad's cousin and son-in-law, Ali, who had adopted Islam as a child and was like a son to the Prophet, should succeed him as leader. On the day of Muhammad's death, Umar acknowledged Abu Bakr as *caliph* (successor) to the Prophet, and soon others followed his example. Umar said he took the action to prevent divisions in the Muslim community.

Abu Bakr ruled as caliph in Medina for two years. He took political charge of the Muslim community and led prayers in the Prophet's place, but he refused to assume Muhammad's role as the interpreter of Islamic doctrine. He left interpretation to the collective judgment of the Prophet's companions. Abu Bakr's example in referring religious decisions to community leaders eventually formed the basis of the Sunni *(SOON ee)* division in Islam. The followers of Sunni Islam are called Sunnites.

Abu Bakr faced revolts by Arabian tribes against the authority of the Islamic state. Some tribes even put forth their own prophets. But within about a year, Abu Bakr put down these revolts, and the tribes accepted Islam.

The Dome of the Rock in Jerusalem is one of the holiest places in Islam. The dome encloses a rock, shown in the foreground, from which the Prophet Muhammad is believed to have ascended to heaven. The dome was built between 688 and 691, during the rule of the Umayyad caliph Abd al-Malik.

Umar. In 634, Abu Bakr died, naming Umar to succeed him as caliph. Umar's 10-year rule became a great period of Islamic expansion. First, he sent Quran reciters to the tribes of Arabia to teach them Islam. Next, he embarked on the full-scale conquest of the Middle East. During this period, Islam was largely a religion of the Arabs, and Umar concentrated on spreading Islam among the tribes of Syria and Iraq. Most Arabs converted to Islam at this time.

By the end of Umar's caliphate in 644, the Muslims had conquered Syria, Palestine, Egypt, and most of Iraq. Because of the great increase in the number of people under their rule, the Muslims set up an administration to govern the new territories. They sent Muslim soldiers and their families to settle in strategically located towns, which rapidly grew into major cities. Each town centered on a main *mosque* (Muslim place of worship) and was ruled by the provincial governor. Soldiers and other Muslims each received a payment from a share of the booty taken during conquests and taxes from conquered lands. The payments varied depending on how long each person had been a Muslim. Thus, the earliest converts had great political power and often made fortunes.

Uthman. Just before Umar died, he appointed a committee to choose his successor. When the committee asked Ali to be caliph and follow the rulings of his predecessors, he refused. He claimed that he knew more than the previous caliphs about Muhammad's original views and intentions. Uthman, another son-in-law of the Prophet, agreed to the request and became caliph.

Under Uthman, the Muslims completed the conquest of Iran and began to spread across North Africa from Egypt. But political conflicts broke out and marked the end of Muslim political and religious unity. Despite Uthman's piety, his enemies accused him of favoritism and a love of wealth and luxury. Political corruption and stricter economic policies in the provinces caused the Muslims of Egypt to revolt against their governor, Uthman's foster brother. Uthman's half-brother, who was the governor of Kufa in southern Iraq, disgraced himself by appearing drunk in public.

In 656, delegations from Egypt and Iraq arrived in Medina to protest Uthman's policies. Many of Medina's citizens also opposed Uthman, including Muhammad's widow Aisha and his son-in-law Ali. But Ali had no desire to start a rebellion. When Uthman appealed to him to help settle the dispute, he did so, but he asked the caliph to change his policies. Ali's attempt at a settlement failed, and protesters killed Uthman. Immediately afterward, a delegation went to Ali and proclaimed him caliph. At first, he refused because Uthman had been murdered. But he consented after other delegations from Medina and the provinces urged him to accept.

Ali. The caliphate of Ali marks the beginning of the Shiite division of Islam. As the closest living relative of Muhammad, Ali claimed a unique understanding of the Prophet's teachings. Ali's followers, the Shiah *(SHEE ah),* considered him the only true *Imam* (Muslim leader). After Ali's death, his sons and descendants led the Shiah as Imams. Although the Shiites agreed with most Muslims on matters of doctrine, they felt their Imams should have priority in the interpretation of Islamic doctrine.

When Ali accepted the caliphate, several Muslim leaders opposed him, including Muhammad's widow Aisha and Muawiya, the governor of Syria and Uthman's cousin. From this point, Medina no longer served as the capital of the Islamic state. Ali moved to Kufa (now Al Kufah, Iraq), where most of his supporters lived. Aisha and her allies moved to Basra (now Al Basrah, Iraq). In 656, Ali and Aisha fought the Battle of the Camel, the first conflict of Muslim against Muslim. Ali won the battle, named for the camel that carried Aisha.

British Library, London/Art Resource

The Prophet Muhammad, according to Islam, ascended to heaven on the back of a creature called Buraq. Muhammad's face is veiled because of a Muslim prohibition on showing the Prophet's face.

Ali next turned against Muawiya, who demanded that Ali produce Uthman's assassins or be considered an accomplice in the murder. In 657, the armies of Ali and Muawiya fought at Siffin, on the Euphrates River in northern Syria. During the battle, soldiers in Muawiya's army raised pages of the Quran on their spears and called for arbitrators to settle the conflict peacefully. Ali agreed, so the battle ended indecisively. Many of Ali's followers, however, opposed arbitration and turned against him. These followers, called Kharijites, which means *secessionists,* make up the third major division in Islam, along with the Sunnites and the Shiites.

The Kharijites rejected both Muawiya and Ali. They felt the best Muslim should be caliph, even if that person were a slave. In 658, Ali fought the Kharijites at Nahrawan in central Iraq. He won the battle, but many faithful Muslims were killed in the fighting, causing

even more people to turn against him. In 660, Muawiya was proclaimed caliph in Jerusalem. In 661, Ali, who refused to step down as caliph, was murdered by a Kharijite assassin seeking revenge for Nahrawan.

The Muslim empire

The Umayyads. After the death of Ali, Muawiya founded the Umayyad *(oo MY ad)* caliphate and made Damascus his capital in 661. Under the Umayyads, the Islamic state became an imperial power, much like its rival, the Byzantine Empire. When choosing ruling officials, the Umayyads preferred Arabs over their non-Arab subjects. Under the Umayyads, the Muslims extended their conquests into Afghanistan and central Asia in the east and across North Africa and into Spain in the west. Their main source of power was an Arab army based in Syria. This army swore personal loyalty to the caliph and acted as his bodyguard. Administratively, the Umayyads adopted many of the customs and institutions of the Byzantine Empire and of the Sassanian Empire, which had ruled Persia until the Muslim conquest.

In 680, Muawiya died and was succeeded by his son Yazid, who became notorious for corruption and misrule. The inhabitants of Medina refused to recognize Yazid. Ali's son Husayn also rose against him. Husayn set off toward Kufa to gather support, but the Kufans refused to help him. The Umayyads massacred Husayn and his small band of followers at Karbala in southern Iraq. This violence against the Prophet's family shocked the Muslim world.

In 684, Yazid's cousin Marwan, a former aide of Uthman, succeeded to power in Syria. Abd al-Malik, Marwan's son, was proclaimed caliph in 685, and began the second phase of Umayyad rule. The later Umayyads faced a long series of revolts. Kharijites, Shiites, and other rebels agitated against them in the name of Islam, advocating a return to the religion as it was practiced by Muhammad and his companions.

The Abbasids. By the mid-700's, important changes had occurred in Muslim society. An increasing rate of conversion to Islam, combined with intermarriage between Arabs and non-Arabs, had transformed the makeup of the Muslim population. For the first time, non-Arab Muslims outnumbered Arab Muslims in many regions. Many of the Kharijite and Shiite rebels against the Umayyads came from non-Arab converts. In North Africa, the Kharijites were mainly Berbers. In eastern Iran, many Kharijites and Shiites were Persian. Such new Muslims demanded equality with Arabs. The new Muslims called for a society in which each Muslim would have the same privileges and be subject to the same taxes, regardless of ethnic background. Religious scholars, who sought a return to a higher standard of piety, supported them.

The Abbasids *(uh BAS ihdz)* took up the cause of the new Muslims. The Abbasids descended from Muhammad's uncle Abbas. At first they joined forces with the Shiites, claiming that the most qualified member of the Prophet's family should be caliph. The Abbasids eventually dominated the anti-Umayyad movement. The Abbasids called for revenge against the Umayyads for their treatment of Muhammad's family. They conquered the Umayyads in 750, after a struggle lasting only three years. When some descendants of Ali claimed that one of them should hold the office of caliph, the Abbasids suppressed them and their supporters.

From 750 to the mid-800's, the Abbasids transformed the Islamic state into an empire that blended many cultures and was ruled by an absolute monarch. The caliph continued to uphold the sunna of the Prophet and the Islamic Shari`a. The Abbasid caliph was a magnificent ruler, living in splendid isolation and surrounded by thousands of officials and slaves. Only the most privileged were allowed to speak with him.

The capital of the Abbasids was Baghdad in central Iraq, established in 762 by the caliph Abu Jafar al-Mansur. At the heart of Baghdad was a huge administrative complex called the City of Peace. Beyond its walls stretched Baghdad and its suburbs, with more than a million inhabitants.

The Abbasid Empire was a highly centralized monarchy, the greatest since the Roman Empire. It drew support from one of the largest and most integrated economic systems known until modern times. Through the Persian Gulf flowed the products of east Africa, Arabia, India, southeast Asia, and China. Across the desert from Syria and down the Euphrates River came goods from North Africa, Egypt, and the Mediterranean. To Muslim scholars and historians of this period, Baghdad was the center of the world.

During the Abbasid period, the Islamic arts and sciences flourished. Several schools of Islamic law formed during this period. Study of the Qur'ān and of Arabic grammar developed. In about 830, the caliph al-Mamun created a research library called the House of Wisdom. A staff translated the works of Plato, Aristotle, and other Greek philosophers into Arabic. These translations stimulated the development of an Islamic philosophical tradition that played a major role in reintroducing many important works and ideas from Greek philosophy into western Europe.

The Abbasid period also witnessed the emergence of Sufism, which is Islamic mysticism. The Sufis do not make up a separate division, like the Shiites and Kharijites. Most Sufis are Sunni Muslims and see Sufism as a school of thought within mainstream Islam. Most Sufis follow the Shari`a closely and differ from other Muslims only in their desire to create a closer personal relationship with Allah.

The fall of the Abbasids. As a highly centralized monarchy, the Abbasid Empire lasted little more than 100 years. Its authority never became fully established in the Islamic west. In 756, Abd al-Rahman, an Umayyad prince who had escaped to Spain, founded a second Umayyad line of rulers that lasted until 1031. In the 780's, Idris ibn Abdallah, a descendant of Ali's son Hasan, fled from Abbasid persecution and created an independent kingdom in Morocco. In the 800's, the Abbasid governors of Tunisia and Egypt broke away from Baghdad and formed their own states.

From 929 to 1031, there were three competing caliphates at one time—the Abbasids in Iraq, an Umayyad caliphate in Spain, and the Fatimids in North Africa and, from 969, in Egypt. By this time, the Abbasids ruled over the Muslim world in name only. From the mid-900's until the Mongols captured Baghdad in 1258, most of the caliphs were puppet rulers, serving at the whim of military dictators. The blending of many cul-

tures within Islam had led to the development of multiple centers of power and culture in the Muslim world. The diversity of the Muslim world continues to this day.

The spread of Islam

The Mongols killed the last Abbasid caliph in 1258 and captured Baghdad, but the vitality of the Muslims did not diminish. Socially and culturally, the Muslim world became more diverse than ever. In west Africa and what are now Malaysia and Indonesia, Muslim merchants and scholars introduced Islam and converted kings, who made Islam the state religion. In China, the Muslim population also grew from communities of merchants. In Africa south of the Sahara, large-scale conversions began in the 1400's. Most of these conversions resulted from trade and personal contact rather than conquest.

Muslim power reached a new height in the 1500's. By that century, the Muslims had established three powerful empires: (1) the Ottoman Empire, which began in what is now Turkey; (2) the Safavid dynasty in Iran; and (3) the Mughal Empire in India.

The Ottoman Empire lasted from about 1300 to 1922. The Ottomans were named after Osman I, a Turkish chieftain who founded a state in Anatolia, now Turkey, in the late 1200's. The Ottomans claimed to be the champions of Sunni Islam. In 1453, Sultan Mehmet II conquered Constantinople, the capital of the Byzantine Empire. The city, now called Istanbul, became the capital of the Ottoman Empire.

Gouache manuscript painting (1588); Giraudon/Art Resource

The Ottoman Empire under Sultan Süleyman I dominated much of Europe and North Africa. Süleyman led Muslim armies as far west as the walls of Vienna, *shown here,* in 1529.

By 1600, the Ottoman Empire formed a crescent around the Mediterranean extending from Hungary in eastern Europe through Palestine and Egypt to Algeria in North Africa. Under the reign of Sultan Süleyman I in the 1500's, the Muslim world achieved its greatest level of unity since the time of the Abbasids. Under the Ottomans, many cultures maintained their identities within Muslim society. The Ottoman sultans were Turkish, but the generals, admirals, and administrators of the Ottoman Empire came from throughout the Mediterranean world. Many Ottoman aristocrats were skilled in the arts, languages, and literature, and they set the standard for culture in the Muslim world.

Many Ottoman officials came from Christian families. Each year, recruiting teams collected boys from eastern Europe. The youths were taken to Istanbul, converted to Islam, and educated. Legally, they became slaves of the sultan and were supposed to be loyal only to him. The most physically active boys became "Men of the Sword" and served in the Janissary Corps, a special division of infantry that formed the core of the Ottoman army. The more scholarly students became "Men of the Pen" and served in administrative posts, from which they could rise to the rank of grand vizier, the highest Ottoman official after the sultan.

The Safavid dynasty. The main rivals of the Ottomans were the Safavids in Iran. The Safavids, originally Sufis from northwestern Iran, rose to power as the leaders of Shiite Turks. Under Shah Ismail I in the early 1500's, Iran, formerly a Sunni country, converted to Shiism. Through the middle of the 1600's, the Ottomans and Safavids fought each other in a series of devastating wars. The wars ended in a costly stalemate that drained the resources of both empires. Safavid kings ruled Iran until 1722.

The Mughal Empire of India was founded by Babur, a central Asian prince, in 1526. Using firearms, Babur's small invasion force easily defeated much larger Indian armies. The Mughal Empire reached its peak under Akbar, who reigned from 1556 to 1605. His empire covered two-thirds of South Asia, including most of present-day Afghanistan, Pakistan, north and central India, and Bangladesh. Mughal society under Akbar tolerated many different religious beliefs. Akbar's son Jahangir was a Muslim, but he had a Hindu mother. The empire officially was Sunni, but many Shiites held high offices. The empire grew less tolerant and declined in the 1700's. It ended in 1858.

Colonialism

Domination by the West. In 1798, the French general Napoleon invaded and conquered Egypt. The conquest shocked the Muslim world. Since the time of the Abbasids, Muslims had viewed Europe as a barbaric land, where culture and morality remained at a low level. With Egypt's defeat, Muslims faced a Europe that had superior military strength and openly challenged their social values. Muslims were impressed by Western mili-

Gouache and gold painting on paper (1590); Victoria & Albert Museum, London/Art Resource

Babur founded the Mughal Empire in India in 1526. Babur was a cultured ruler who encouraged religious tolerance. This painting shows him supervising the laying out of a garden in Afghanistan.

tary technology and influenced by their contacts with European scientists and historians. Muslim delegations began to travel to Europe to study the latest trends in science and philosophy.

Although the French left Egypt in 1801, they returned to the Muslim world, invading Algeria in 1830. During the last half of the 1800's and the early 1900's, Europe either directly or indirectly controlled every Muslim country except Arabia, Turkey, and Iran. Most states of north and west Africa became French colonies. British political influence and territorial control in India grew in the 1700's and 1800's. Egypt was under British control from 1882. Indonesia began to fall under the rule of the Netherlands as early as the 1600's.

Colonialism caused drastic changes within all Muslim societies. Colonial governments brought administrative changes and built roads, railroads, and bridges. But colonial authorities also deprived Islam of its former role in the organization of social and economic life. They reorganized the Islamic sharīʿa and supplemented it with a European system of laws. To the present day, most Muslim countries have a dual legal system. Laws governing marriage, family, inheritance, and other personal matters are usually based on the sharīʿa, while most criminal and commercial laws are based on European models.

Reform and renewal. The most influential Muslim movement of the colonial period was the Salafiyyah (Way of the Ancestors). It was founded by Jamal al-Din al-Afghani, an Iranian politician and philosopher, and Muhammad Abduh, an Egyptian theologian and expert on Islamic law. The Salafiyyah attempted to reform Islam using modern Western concepts of reason and science. Afghani also helped found Pan-Islamism, a movement that called for the unity of all Muslims. He feared that nationalism would divide the Muslim world and believed that Muslim unity was more important than ethnic identity. Muḥammad Abduh's main concerns were the reform of Islamic law and theology. He rejected the blind acceptance of the past.

The most important successors of the Salafiyyah movement were the Muslim Brotherhood, the Jamaat-i-Islami, and the Muhammadiyah. Hasan al-Banna, an Egyptian teacher, founded the Muslim Brotherhood in 1928. The organization inspired Islamic reform movements in other Arab countries, including Jordan, Sudan, and Syria. The Muslim Brotherhood started as a religious and philanthropic society that promoted morality and good works. It eventually moved into politics and supported the replacement of nonreligious governments with governments based on Islamic principles. Today, the Muslim Brotherhood is one of the most influential movements in the Muslim world. It is affiliated with Islamic reform movements in non-Arab countries, such as Pakistan, Bangladesh, and Malaysia. It also influences Islamic centers in the United States.

The Jamaat-i-Islami was founded in 1941 in what is now Pakistan by Abu al-Ala Maududi, who was dedicated to reviving Islam in India. After British rule ended in India in 1947, he supported the creation of an Islamic republic in Pakistan. Throughout its history, the Jamaat-i-Islami has supported conservative Muslim politics. The leaders have called for curtailing the influence of minority Islamic sects in Pakistan and have stirred up opposition to nonreligious governments. Although its political influence declined after the death of its founder, the Jamaat-i-Islami continues to attract a following among university students and the lower middle class. It also has considerable influence among Pakistani immigrants in Europe and the United States.

The Muhammadiyah is the largest Muslim reform organization in Southeast Asia. It was founded on the Indonesian island of Java in 1912 and was heavily influenced by the views of Muhammad Abduh. The Muhammadiyah supports a form of Islam based on reason. It has called for the social liberation of Muslim women. Aishiya, the Muhammadiyah's women's organization, was named after the Prophet's wife. It ranks as one of the most dynamic women's organizations in the Muslim world.

The Muslim world today

A goal held by many Muslims is the formation of a unified community of believers. But the great diversity of the modern Muslim world acts against this goal. Although most Muslims believe that "Islam is one," there remain important differences of doctrine and practice within the Muslim world. The practice of Islam in Morocco, for example, differs in many ways from the practice of Islam in Iran or Oman. Only about 15 percent of

© Anis Hamdani, Gamma/Liaison

A religious procession in Karachi, Pakistan, honors the birthday of the Prophet Muhammad. Pakistan is one of the largest Muslim nations in the world. Although Islam originated in the Middle East, the majority of Muslims today live in other parts of the world, especially south Asia.

Muslims are Arabs. The largest group of Muslims live in south Asia in Bangladesh, India, and Pakistan and speak languages, such as Bengali and Urdu, which are much different from Arabic. The single nation with the largest Muslim population is Indonesia in Southeast Asia. And as Islam becomes more prominent in Europe and North America, new cultural forms will add to this diversity.

Cultural differences lie behind many social controversies in Islam, especially regarding the role of women. The treatment of women varies widely throughout the Muslim world. Women in such countries as Afghanistan and Saudi Arabia live largely in seclusion and have little social or economic independence. In other countries, however, including Bangladesh, Malaysia, Pakistan, Turkey, and Tunisia, women are elected to parliament, serve as government officials, and may even become prime minister.

In the late 1900's and early 2000's, some Islamic fundamentalist groups strongly opposed countries with governments that did not follow their interpretation of Islam. Some declared the United States an enemy of Islam. They especially objected to U.S. support of Israel and the presence of American troops in Saudi Arabia. Some Islamic extremists called for a "holy war" against the United States and launched terrorist attacks against American citizens and property. Vincent J. Cornell

Muslin, *MUHZ luhn,* is a closely woven white or unbleached cloth made from corded cotton yarn. It is named for the city of Mosul, in Iraq, where it was first made. The British call sheer cotton fabrics *muslin.* In the United States, *muslin* means a firm cloth for everyday use. Wide muslin is called *sheeting.* Christine W. Jarvis

Mussel, *MUHS uhl,* is a water animal protected by a hard shell. Mussels live in oceans and in fresh water. Their shell consists of two plates called *valves,* which are joined by a hinge. Large *adductor* muscles close the shell tight in case of danger.

Marine mussels usually live in shallow waters along ocean coasts. They attach themselves to rocks by producing strong, sticky *byssal* threads made of protein. Marine mussels form large populations that carpet vast areas. They feed on tiny plantlike organisms called *plankton,* which they trap in their gills. Several marine mussels are eaten by people. One such variety, the blue mussel, has a shell that is bluish-black on the outside. It can grow to about 4 inches (10 centimeters) long.

Freshwater mussels are only distantly related to marine mussels. They often live buried in sandy bottoms of rivers, streams, and lakes. Freshwater mussels were once a major source of *mother-of-pearl,* a rainbow-colored material that lines their shells. Mother-of-pearl is often used in jewelry. Because of overharvesting and damage to their habitat, many freshwater mussels are in danger of becoming extinct. Robert S. Prezant

Scientific classification. Mussels are in the class Bivalvia. Marine mussels belong to the family Mytilidae. The scientific name of the common blue mussel is *Mytilus edulis.* Freshwater mussels are in the family Unionidae.

Musset, *myoo SAY,* **Alfred de** (1810-1857), was a French dramatist and poet. Most of his plays were meant to be read rather than performed on stage. Musset is best known for a series of comedies of manners. These works, known collectively as *Comédies et Proverbes,* reflect a witty, poetic style and deep insights into human behavior. His plays deal with the pain of love and with the conflict between innocence and cynical sophistication. Musset's *Lorenzaccio* (1834) was a historical drama set in Florence, Italy. It was first staged in 1896.

Musset was born in Paris. He believed that poetry should express the innermost feelings of the writer and that suffering is essential for the creation of good literature. Among his most famous poems are *Nuits (Nights),* published between 1835 and 1837. They describe his sorrow after the end of his love affair with the famous woman writer George Sand. Dora E. Polachek

Mussolini, *MOO suh LEE nee* or *moos SOH LEE nee,* **Benito,** *beh NEE toh* (1883-1945), founded fascism and ruled Italy for almost 21 years, most of that time as dictator. He dreamed of building Italy into a great empire, but he led his nation to defeat in World War II (1939-1945) and was executed by his own people.

Early life. Mussolini was born in Dovia, near Forlì, in northeastern Italy. He earned a teaching certificate and briefly taught in an elementary school. From 1902 to 1904, he lived in Switzerland, where he increased his knowledge of socialism. Mussolini served in the Italian military in 1905 and 1906, and then taught school again and became a local socialist leader. In 1909, he went to Trent, Austria (now Trento, Italy), and worked for a socialist newspaper. But Austrian authorities expelled him from Austria for revolutionary activities.

In 1912, Mussolini became editor of the Italian Socialist Party's official newspaper. In this paper, he supported Italian involvement in World War I (1914-1918). Many socialists criticized this position. He then resigned as editor and, in November 1914, founded his own newspaper, *Il Popolo d'Italia,* in which he urged Italy to enter the war against Germany and Austria-Hungary. Later that month, the Socialist Party expelled Mussolini. Italy entered the war in 1915, and Mussolini served in the army until he was wounded in 1917.

United Press Int.

Benito Mussolini used dramatic poses. Clenched fist, jutting jaw, and theatrical actions were all part of his fiery speeches. He gained the support of millions of Italians.

Fascist dictator. In 1919, Mussolini founded the *Fasci di Combattimento* (Combat Groups). This movement appealed to war veterans with a program that supported government ownership of national resources and that put the interests of Italy above all others. In 1921, he transformed the Fasci into the National Fascist Party, adopting a more conservative program to gain the support of property-owning Italians. The Black Shirts, armed squads who supported Mussolini, used violence to combat anti-Fascist groups. In 1922, the Black Shirts staged a March on Rome and forced King Victor Emmanuel III to appoint Mussolini prime minister.

In 1925, Mussolini declared a dictatorship. He abolished other political parties and imposed government control on industry, schools, and the press and police. In 1929, he signed agreements that settled long-standing disputes between the government and the Roman Catholic Church. He also sought to make Italy a *corporate state,* in which the government would help resolve disputes between employers and workers. The powerful Mussolini was called *Il Duce* (The Leader).

Foreign policy. Mussolini sought to make Italy a major power and to create an Italian colonial empire. He invaded and conquered Ethiopia in 1935 and 1936. But this action was condemned by Britain, France, and other countries and drove Mussolini toward an alliance with the German dictator, Adolf Hitler. In 1936, Mussolini joined Hitler in sending troops to fight in the Spanish Civil War in support of the rebel leader General Francisco Franco. In 1939, Italy conquered and annexed Albania.

World War II began in 1939, and France and Britain declared war on Germany. After Germany had almost conquered France in 1940, Mussolini entered the war and invaded France. A few days later, France surrendered. But Mussolini's troops soon suffered serious setbacks in North Africa and Greece. They met even stronger opposition after the Soviet Union, and later the United States, joined the war against Italy and Germany.

In July 1943, members of the Italian government deposed Mussolini and restored authority to the king, who then had Mussolini arrested. Mussolini was rescued by German commandos and became the head of a puppet government in northern Italy. In the spring of 1945, the German forces in northern Italy collapsed. On April 27, 1945, Italians opposed to fascism captured Mussolini as he attempted to escape to Switzerland. The next day, he was shot to death. Philip V. Cannistraro

Mussorgsky, *moo SAWRG skee* or *MOO sawrg skee,* **Modest,** *moh DEHST* (1839-1881), a Russian composer, was one of the most original composers in the history of Russian music. Mussorgsky was an undisciplined genius with powerful ideas rather than a polished style. He introduced bold and unusual features into his work.

Mussorgsky's place in music rests primarily on his operas and songs. His *Boris Godunov* (1874) is often considered the greatest Russian opera. This opera reflects the composer's interest in native themes and the Russian people. Mussorgsky was a fine singer and

pianist and wrote many works for solo voice and for piano. As a song composer, his style ranges from lyrical romances to realistic songs. A number of his realistic songs are set to texts he wrote after observing incidents from everyday Russian life. In these songs, Mussorgsky showed a special gift for creating an appropriate vocal line for the rhythms and inflections of Russian speech. His major contribution to piano literature is *Pictures at an Exhibition* (1874). It is also performed in a version orchestrated in 1922 by French composer Maurice Ravel.

At his death, Mussorgsky left several unfinished works. Other Russian composers, particularly Mussorgsky's friend Nikolai Rimsky-Korsakov, completed his scores for performance. The orchestral work *Night on Bald Mountain* (1886) came from Rimsky-Korsakov's reworking of music that had been incorporated into *The Fair at Sorochinsk* (written from 1874 to 1880). Rimsky-Korsakov's versions of the operas *Khovanshchina* (written from 1872 to 1880) and *Boris Godunov* have most often been performed. Mussorgsky was born in Karevo, near Pskov. Edward V. Williams

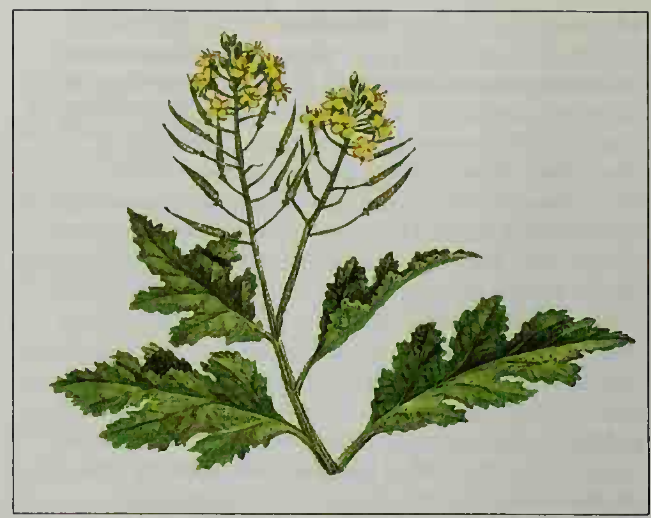
Mustafa Kemal. See Atatürk, Kemal.

Mustang is the name of certain horses that once roamed wild over parts of the American West. Mustangs are descendants of horses brought to America by the Spanish. A large population of wild mustangs developed from the mid-1600's to the early 1900's. *Mustang* perhaps came from the Spanish word *mesteños* or *mestengo*, meaning *strayed*, or *ownerless, horses.* See also Cowboy (His horse). Geo. H. Waring



© Renee Lynn, Photo Researchers

A herd of mustangs roams across a wild horse sanctuary in Redding, California. Large numbers of mustangs once traveled freely over areas of the Western United States.

Mustard is the name of a family of leafy plants commonly used to make tangy food seasonings. People use mustard seeds whole or as a powder or paste in salad dressings, on sandwiches, and in other foods.

Mustard plants usually are *annuals*—that is, they live one year or less. The plants have a strong smell. Their leaves contain jagged *lobes* (segments). Their small yellow flowers have four petals that form a cross. Long, slender pods hold the mustard seeds.

WORLD BOOK illustration by John D. Dawson

The dark green leaves of the mustard plant make an excellent summer vegetable that is high in vitamin content.

People eat the leaves of young mustard plants raw or cooked. Mustard greens provide an excellent source of vitamins A, B, and C.

Popular plants of the mustard family include white mustard, brown mustard, and black mustard. White mustard, also called yellow mustard, grows up to 4 feet (1.2 meters) tall. Many of the most popular mustard pastes in the United States, the United Kingdom, and Germany are made from white or yellow mustard seeds. People also eat the leaves of white or yellow mustard in salads.

Brown mustard can reach 4 feet (1.2 meters) in height. Farmers in China, India, and Japan cultivate this mustard for its oil. In Europe and North America, manufacturers use its seeds to make spicy, French-style mustard, such as Dijon mustard. People eat brown mustard leaves as a boiled vegetable or in salads.

Black mustard grows to about 6 feet (1.8 meters) tall. Once the chief source of mustard products, this plant has been largely replaced by brown mustard, which is easier to harvest with farm machinery. Black mustard can spread quickly and become a weed.

Hot packs containing mustard, called *mustard poultices* or *mustard plasters,* may help relieve chest congestion and sore muscles. Mustard in small doses may increase the appetite and help with digestion. In large doses, however, it can cause vomiting. Stephen Reiners

Scientific classification. Mustard belongs to the mustard family, Brassicaceae or Cruciferae. The scientific name for white or yellow mustard is *Sinapis alba.* Brown mustard is *Brassica juncea,* and black mustard is *B. nigra.*

Mutation is a change in the hereditary material of cells. By altering this material, a mutation changes certain traits. Some mutations produce obvious changes. For example, the variety of grape called *Concord* is the result of a mutation. This mutation caused a wild grapevine to produce grapes that were bigger and sweeter. Mutations may be transmitted to future generations.

Hereditary material consists of *genes* and *chromosomes.* Genes, which are composed of a substance called *deoxyribonucleic acid* (DNA), determine the hereditary traits of an organism. The genes are lined up

along the chromosomes, which are microscopic threadlike bodies. A mutation can affect an individual gene or an entire chromosome. A gene mutation occurs if there are slight chemical changes in DNA. Sickle cell anemia is a blood disease that is caused by a gene mutation. In a person with sickle cell anemia, a minor change occurs in the DNA of a gene that controls the production of red blood cells. A chromosome mutation occurs if the number or arrangement of chromosomes changes. Down syndrome is a mental and physical disorder that is caused by a chromosome mutation. Down syndrome occurs if a person is born with an extra copy of a certain chromosome.

Scientists do not know what causes most mutations, even though these changes occur at known rates. Some mutations are caused by such agents as ultraviolet light, X rays, and certain chemicals. Others are caused by *transposable elements*—certain segments of DNA that can change position within the chromosomes. Agents that cause mutations are called *mutagens.* The type of mutation that will be caused by a mutagen cannot be predicted.

An organism can pass a mutation on to its offspring only if the mutation affects cells that produce eggs or sperm. This type of mutation is called a *germinal mutation.* The other type of mutation, called a *somatic mutation,* occurs in other cells of the body.

A mutation may or may not have a visible effect on the organism that carries it. Most mutations that cause a visible change are harmful. However, some of these mutations enable an organism to survive and reproduce better than other members of its species. Such beneficial mutations—if they are germinal—are the basis of evolution. If the mutant organism passes a beneficial trait on to its offspring, they also will have an advantage in survival and reproduction. After many generations, most members of the species will have the trait.

Breeders use mutations to produce new or improved species of crops and livestock. They do this by breeding certain plants and animals that have one or more favorable mutations. These plants and animals are called *sports.* Daniel L. Hartl

Sport

Mutiny is any unlawful attempt by military personnel to seize or set aside military authority. The term often refers to an unlawful attempt by a crew to take command of a naval ship. United States military law defines two types of mutiny. One type involves the use of violence or creation of a disturbance by one or more persons acting individually. The second type of mutiny involves two or more people who jointly refuse to obey orders or perform military duties. This type of mutiny need not involve a disturbance. In the United States, the maximum punishment for mutiny is death.

Robert C. Mueller

See also Amistad Rebellion.

Mutsuhito. See Meiji, Emperor.

Mutton is meat obtained from sheep that are more than a year old and, in most cases, that weigh more than 100 pounds (45 kilograms). Mutton differs from lamb, which is the meat obtained from sheep less than a year old. Mutton is less tender and has a stronger flavor than lamb. In addition, mutton has a darker color than lamb. This color ranges from dark pink to deep red.

Mutton is a good source of protein, B vitamins, phosphorus, and iron. It is a popular food in Australia, the United Kingdom, and New Zealand. However, people in Canada and the United States eat little mutton, and it is seldom available in supermarkets. Donald H. Beermann

See also Lamb.

Mutual fund is a company that pools funds from many investors and uses them to buy stocks and other securities. The investors receive shares in the mutual fund. The price of a share rises or falls according to the market prices of the securities owned by the fund.

A mutual fund issues no fixed number of shares. Any investor may buy shares from the company at any time. For this reason, mutual funds are also called *open-end investment companies.* They differ from *publicly traded investment funds,* formerly called *closed-end investment companies,* which have a fixed number of shares that are traded on stock exchanges.

Mutual funds are either *load funds* or *no-load funds.* Load funds authorize dealers to sell shares in the fund to investors. The price of a share equals the *net asset value* per share plus a *load.* The net asset value is determined by the current market value of the securities in the fund. The load is a sales charge that includes a commission for the dealer. In a no-load fund, the investor buys shares at their net asset value directly from the fund. There is no sales charge. If investors in any mutual fund want to sell their shares, they must sell them back to the fund. The fund must buy its shares back for their approximate net asset value.

Some mutual funds, called *growth funds,* invest mostly in common stocks of companies that have grown rapidly. *Balanced funds* seek more *diversification* (distribution of investments) to reduce risk. They build a *portfolio* (collection of securities) that includes bonds as well as stocks. *Income funds* seek to provide higher current income for investors by acquiring bonds and preferred stocks that offer higher-than-average dividends or interest. *Money market funds* invest in Treasury bills and other short-term securities whose prices fluctuate relatively little.

People buy shares of mutual funds in part because the funds employ professional investment managers. These experts select stocks or bonds in a mix that they believe will satisfy the return and risk goals of investors. A mutual fund also enables people to own a large number and wide variety of securities. As a result, a mutual fund shareholder has less risk of loss than does an individual who invests in only one security.

Some mutual funds are *index funds,* which try to match the performance of a targeted group of securities. *Stock index funds,* for example, may seek to reflect the performance of the stocks of only large companies or of an entire stock market. Such funds require little management and charge relatively low fees.

The magnificent Shwe Dagon pagoda is the most famous of Myanmar's thousands of Buddhist temples. The pagoda is in Yangon, the country's capital and largest city.

Myanmar

Myanmar, *MYAHN mah,* formerly called Burma, is a country in Southeast Asia. It lies along the Bay of Bengal. Mountains border Myanmar on the west, north, and east. They enclose the Irrawaddy River Valley. The Irrawaddy River empties into the Bay of Bengal through many mouths, forming a delta. Yangon, Myanmar's capital and largest city, lies on the delta. Yangon is also spelled Rangoon.

The people of Myanmar are called the Burmese. The great majority of them are Buddhists and live in villages on the delta and in the Irrawaddy Valley. They make a bare living farming the land.

People have lived in what is now Myanmar since prehistoric times. Several kingdoms arose and fell in the region from the A.D. 1000's to the 1800's, when Britain conquered the country. The nation won its independence with the name Burma in 1948. In 1989, the military government announced that it had changed the official name of the country from the Union of Burma to the Union of Myanmar. Some people, especially those who are opponents of the military regime, still refer to the country as Burma.

James F. Guyot, the contributor of this article, is Professor of Political Science and Public Administration at the City University of New York.

Government

National government. A military group called the State Peace and Development Council controls Myanmar's government. The senior general heads the council and serves as prime minister and minister of defense.

The council, which was known until 1997 as the State Law and Order Restoration Council (SLORC), came to

Facts in brief

Capital: Yangon.
Official language: Burmese.
Area: 261,228 mi^2 (676,578 km^2). *Greatest distances*—north-south, 1,300 mi (2,090 km); east-west, 580 mi (930 km). *Coastline*—1,650 mi (2,655 km).
Elevation: *Highest*—Hkakabo Razi, 19,296 ft (5,881 m) above sea level. *Lowest*—sea level.
Population: *Estimated 2002 population*—46,648,000; density, 179 per mi^2 (69 per km^2); distribution, 74 percent rural, 26 percent urban. *1983 census*—35,307,913.
Chief products: *Agriculture*—rice, vegetables and fruits, sugar cane, peanuts, sesame seeds, corn, wheat, sunflowers, tobacco, jute, cotton, rubber. *Forestry*—teak. *Manufacturing*—textiles, fertilizer, processed foods. *Mining*—natural gas, petroleum, coal, zinc, lead, tin, silver, jade, rubies, sapphires.

power through a military coup in 1988. The leaders of the coup dissolved the legislature and other government institutions. In 1990, they held multiparty elections. The main opposition party, the National League for Democracy (NLD), won a majority of seats. But the SLORC refused to allow a transfer of power until a new constitution was written and approved, with a leading role for the military.

Local government. Myanmar is divided into 14 large administrative units. They consist of 7 *divisions* and 7 *states.* The divisions are inhabited chiefly by Myanmar's largest ethnic group, the Burmans. Other ethnic groups live mainly in the states. The divisions and states are divided into many smaller units. Each unit of local government is directed by a Peace and Development Council of military, civil, and police commanders.

Armed forces. Myanmar's army, navy, and air force have about 400,000 members. Most members of the military serve in the army. Myanmar has a police force of about 50,000 members.

People

Ancestry. Most Burmese are descendants of various peoples who moved into the region from central Asia. The Burmans, Myanmar's largest ethnic group, make up about two-thirds of the population. Other ethnic groups include the Karen, Shan, Arakanese, Chin, Kachin, Mon, Naga, and Wa. Most members of these groups live in the hills and mountains bordering Myanmar. Each of these *hill peoples* seeks to preserve its own culture. Since 1948, several groups have fought against the government to obtain more rights. Some Chinese and Indian people live in Myanmar's cities and towns.

Languages. Burmese is the official language of Myanmar. It is related to Tibetan. Nearly all the people speak Burmese, and many of them also speak English. In addition, many hill peoples have languages of their own.

Religion. About 85 percent of Myanmar's people belong to the Theravada school of Buddhism. Buddhism, which teaches that people can find happiness only by freeing themselves of worldly desires, strongly influences family and community life. Other religious groups in Myanmar include Christians, Hindus, and Muslims.

Way of life. The majority of Myanmar's people live in farm villages. Most villages consist of about 50 to 100 bamboo houses with thatch roofs. The houses are built on poles above the ground for protection against floods and wild animals. Most villages have a Buddhist monastery, which is the center of much social as well as religious activity. Boys spend from a few days to several months in the monastery after an adulthood ceremony called *shin-pyu.* In the ceremony, the boys' heads are shaved to symbolize their temporary rejection of the world. Girls mark their entry into adulthood with an earlobe-piercing ceremony called *nahtwin,* after which they receive their first pair of earrings.

In towns and cities, many people live in small brick or concrete buildings and work for the government or in trade or industry. City life has more leisure and cultural activities than rural life and moves at a faster pace. But most city people keep close ties with their family and ethnic group, and religion remains important to them.

In both rural and urban areas, men and women usually wear a *longyi,* a long, tightly wrapped skirt made from a cylinder of cotton cloth. Women's longyis have bright colors and patterns and are bound at the side. Men's longyis often have a checked pattern and are bound in front. With the longyi, women wear a blouse, and men wear a shirt. On special occasions, men may wear a silk jacket and a *gaungbaung,* a small headdress made of cloth wrapped around a wicker frame.

Burmese women have more rights than do women in some other Asian countries. In Myanmar, a woman keeps her name after marriage and owns property equally with her husband. In most Burmese families, the mother manages finances and runs the household. Many of the women work outside the home, and some of them own or manage a business.

Food. The people of Myanmar eat rice with almost every meal. The rice is often flavored with chili peppers. Fish or vegetables may also be added. The Burmese like fish, shrimp, and chicken but rarely eat beef or other red meats. Seafood and meat seasonings include onions, garlic, ginger, and *ngapi,* a sharp paste made from preserved fish or shrimp. The Burmese also like bananas, citrus fruits, and Southeast Asian fruits called *durians.*

Recreation. Popular spectator sports include soccer and a form of boxing that allows hitting with any part of the body. The favorite participant sport is *chinlon,* in which a ball of woven cane is passed from player to

Symbols of Myanmar. The official flag of Myanmar's government was adopted in 1974. The cogwheel and rice plant stand for industry and agriculture, and the 14 stars for Myanmar's 7 states and 7 divisions. Blue symbolizes peace, and red, courage. The coat of arms has a map of Myanmar in the center. The star stands for independence.

Myanmar lies on the Southeast Asian mainland along the Bay of Bengal. It borders Bangladesh, India, China, Laos, and Thailand.

player by hitting it with the feet, knees, or head.

The Burmese people enjoy many festivals. The most popular one is held for three days before the Buddhist New Year begins, usually in April during the hot, dry season. People dump water on one another in a rowdy celebration that leaves everyone soaked. The New Year festival and many others include a *pwe,* an all-night performance by actors, dancers, singers, and clowns.

Education. About 80 percent of Myanmar's people aged 15 or older can read and write. Myanmar law requires children from 5 through 9 years old to attend school. The government offers free education from kindergarten through the university level. But education beyond elementary school is available only in the larger towns and cities. Major universities are in Yangon and Mandalay. Myanmar also has many colleges and technical schools. However, most of them have been closed several times since 1988 because of political protests.

The arts. The best-known Burmese works of art are the thousands of *pagodas* (towerlike temples) found throughout the country. The most famous pagoda is the Shwe Dagon Pagoda in Yangon. The golden-domed structure rises 326 feet (99 meters) above a marble platform on a hilltop. The ancient city of Pagan has hundreds of pagodas. Burmese craftworkers are known for their woodcarving, lacquerware, and jewelry.

The land and climate

Land regions. Myanmar has three main land regions. They are (1) the Eastern Mountain System, (2) the Western Mountain Belt, and (3) the Central Belt.

The Eastern Mountain System separates Myanmar from Thailand, Laos, and China. The region includes the long, narrow Tenasserim Coast bordering the Andaman Sea and the hilly Shan Plateau to the north. Some of the world's finest jade and rubies come from the region. The area also has deposits of silver, lead, and zinc.

The Western Mountain Belt is a region of thick forests along the border between Myanmar and India. A group of low mountains called the Arakan Yoma forms the southern part of the region and extends to the Bay of Bengal. A narrow plain of rich farmland borders the bay.

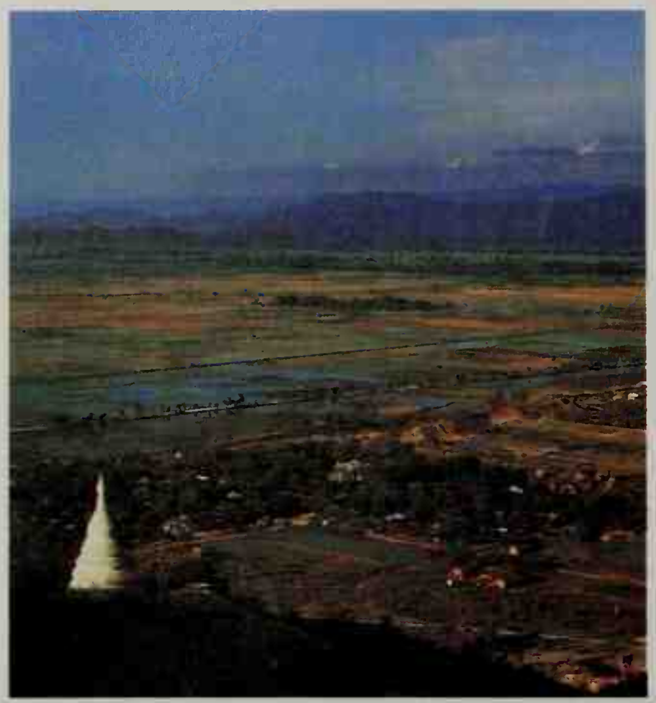
The Central Belt lies between the eastern and western mountain regions. It includes Myanmar's highest mountains in the far north. Hkakabo Razi, the tallest peak, rises 19,296 feet (5,881 meters) above sea level. The Central Belt consists chiefly of the Irrawaddy and Sittang river valleys. The Irrawaddy River flows about 1,250 miles (2,010 kilometers) down the middle of the country to the Bay of Bengal. It is Myanmar's major transportation route. The 350-mile (563-kilometer) Sittang River lies east of the Irrawaddy. Farmers use water from the rivers to irrigate their rice fields.

Climate. Most of Myanmar has a tropical climate. Temperatures in Mandalay, in central Myanmar, average 68 °F (20 °C) in January and 85 °F (29 °C) in July. Temperatures in Yangon, on the delta, average 77 °F (25 °C) in January and 80 °F (27 °C) in July. Myanmar has three seasons: (1) rainy, (2) cool, and (3) hot.

The rainy season, during which Myanmar receives nearly all its rain, lasts from late May to October. Rainfall varies greatly in each region. For example, the Mandalay area receives only about 30 inches (76 centimeters) of rain a year. The Tenasserim Coast, however, is drenched with over 200 inches (510 centimeters). The heavy rainfall is brought by seasonal winds called *monsoons,* which sweep northeastward from the Indian Ocean.

The cool season lasts from late October to mid-February. Temperatures are lowest at this time, though the climate remains tropical throughout most of Myanmar.

The hot season lasts from late February to about mid-May. During this season, temperatures often top 100 °F (38 °C) in many parts of Myanmar.



Economy

Myanmar's economy is based mainly on agriculture. The government owns all the land. Government factories produce about half the industrial output.

Agriculture, forestry, and fishing. Rice is Myanmar's chief crop, and rice fields cover more than half the farmland. Much of the rice is exported. Other crops include vegetables and fruits, sugar cane, peanuts, sesame seeds, corn, wheat, millet, tobacco, jute, cotton, and rubber. Most crops are raised on small family farms.

A "floating market" is a colorful tradition on Inle Lake in central Myanmar. Farmers, craftworkers, and other people in the area gather in boats every five days to trade their specialties, such as rice cakes, fish, fruits and vegetables, farm tools, and silk.

© John Elk III, Bruce Coleman Inc.

Rice fields surround a village in the Irrawaddy River Valley. The spire of a pagoda rises at the left. Rice is Myanmar's chief crop.

Forests cover about half of Myanmar. About 80 percent of the world's teakwood grows there. Fish and shellfish are caught in Myanmar's rivers and coastal waters. Many people also raise fish in village ponds.

Manufacturing. Most manufactured goods are produced for local use. They include processed foods, textiles, and fertilizer. Yangon is the chief industrial center.

Mining. Myanmar has a wealth of minerals, including zinc, lead, tin, tungsten, and silver. It is also rich in jade and such precious stones as rubies and sapphires. But much of Myanmar's mineral wealth is undeveloped.

Service industries. Many service industries workers are government administrators. Others work for schools, hospitals, and other institutions that provide community services. Service industries workers also include people employed in trade, transportation, and communication. Tourism is also important.

Trade. Teak and rice account for about one-third of Myanmar's export income. In addition, there are extensive illegal exports of gems and opium. Other Asian countries buy most of Myanmar's exports. The nation's leading imports include many kinds of consumer goods as well as machinery, transportation equipment, fertilizer, and chemicals. Many of Myanmar's imports come from China, Japan, Singapore, and Thailand.

Transportation. Most freight travels by riverboats on Myanmar's more than 5,000 miles (8,000 kilometers) of inland waterways. Freight is also carried by trucks and railroads. Myanmar has about 17,000 miles (27,000 kilometers) of roads and about 2,500 miles (4,000 kilometers) of railroad track. Few people own an automobile. Many people travel between cities on boats. Oxcarts are common in rural areas. Myanmar's chief seaports are Yangon, Bassein, Moulmein, and Sittwe. Mandalay is a major inland port and transportation center. Yangon and Mandalay have international airports.

Communication. The government of Myanmar controls mass communication. It publishes daily newspapers in Burmese and English. Some magazines and books are published privately but under strict censorship. Government radio programs are broadcast in Burmese, English, and local languages. Government TV broadcasts began in 1980.

History

Early days. The first known people to live in what is now Myanmar were the Mon. They shared a culture with the Khmer, a people who lived in what is now Cambodia. The Mon moved into the Myanmar region as early as 3000 B.C. and settled near the mouths of the Salween and Sittang rivers. The peoples who came later migrated from an area in central Asia that is now southwestern China. The Pyu arrived in the A.D. 600's. The Burmans, Chin, Kachin, Karen, and Shan came during the 800's. Most of these peoples lived apart from one another and kept their own cultures.

In 1044, a Burman ruler named Anawrahta united the region and founded a kingdom that lasted nearly 250 years. The kingdom's capital, Pagan, lay on the Irrawaddy River in the central part of the country. The Burmans adopted features of the Mon and Pyu cultures, including Theravada Buddhism. Mongol invaders led by Kublai Khan captured Pagan in 1287, shattering the kingdom. A new Burman kingdom arose at Toungoo during the 1500's. It was brought down by a Mon rebellion in 1752.

British conquest and rule. The last Burman kingdom was founded by Alaungpaya after the Mon rebellion. Three wars with the British—triggered by Burmese resistance to Britain's commercial and territorial ambitions—led to the kingdom's collapse. The first war was fought from 1824 to 1826, the second in 1852, and the third in 1885. In these wars, the British gradually conquered all of what was then called Burma.

After the third war with Britain, Burma became a province of India, which the British ruled. Under British control, Burma's population and economy grew rapidly. But educated Burmese called for Burma's separation from India and eventual independence. The Burmese protests led Britain to set up a legislature in the 1920's that gave the people a small role in the government.

Protests against British rule continued, however. During the early 1930's, a former Buddhist monk named Saya San led thousands of peasants in an unsuccessful rebellion. At the same time, university students founded the All-Burma Students' Union to work for independence. The students called one another *Thakin* (Master), a title of respect that had been used before only in addressing the British. Leaders of the movement included Thakin Nu and Thakin Aung San. They organized a student strike in 1936. Britain separated Burma from India in 1937 and gave the Burmese partial self-government. But the struggle for full independence continued.

World War II (1939-1945). In 1942, Japan conquered Burma. The Thakins had formed the Burma Independence Army, which helped the Japanese drive the British out of Burma. The Japanese declared Burma independent in 1943, but they actually controlled the government. The Burmese disliked Japanese rule even more than British rule. To fight the Japanese, the Thakins formed the Anti-Fascist People's Freedom League (AFPFL), led by General Aung San. The AFPFL helped Britain and other

Allied powers regain Burma in 1945.

Independence. Following Japan's defeat, the British returned to power in Burma. The AFPFL had become a strong political party, however, and it challenged British control. The British could not govern the country without AFPFL support. They decided in 1947 to name AFPFL President Aung San prime minister of Burma, but he was assassinated before independence came. U Nu, who had been vice president of the AFPFL, became the party's president, and the British appointed him prime minister. Burma won full independence on Jan. 4, 1948.

The new Burmese government faced many problems. Some Communists rebelled against the government in 1948. Various ethnic groups also fought the new government. U Nu's leadership won the support of most Burmese, however. The AFPFL overwhelmingly won elections in 1951 and 1956, though Communist and rebel ethnic groups continued to fight the government.

In 1958, a split developed between U Nu's followers and another AFPFL group. The split threatened to plunge Burma into a deeper civil war. U Nu asked General Ne Win to set up a military government temporarily. Ne Win restored order. He ruled until elections were held in 1960. U Nu's faction won a landslide victory, and he again became prime minister. But he could not control the political and ethnic disputes.

To hold Burma together, Ne Win seized the government in a bloodless take-over in March 1962. He suspended the Constitution and set up a Revolutionary Council of military leaders to rule Burma.

Socialist republic. Ne Win and his Revolutionary Council wanted to make Burma a socialist nation. They explained their ideas in *The Burmese Way to Socialism,* a document that guided many of the government's plans. In July 1962, Ne Win and the council founded the Burma Socialist Programme Party (BSPP). Until 1988, the BSPP was the only political party allowed in Burma. The government began to take strict control of the economy. For several years thereafter, farm production fell, and consumer goods disappeared into the black market. The government rejected most foreign aid and restricted visits by foreign reporters and tourists. It also closed or took over all privately owned newspapers and schools. Student strikes were ended by army gunfire.

On March 2, 1974, the country adopted a new Constitution that officially created the Socialist Republic of the Union of Burma, with Ne Win as president. The Constitution reestablished elections, but the BSPP still held all power. The government removed some restrictions on agriculture and began to accept more foreign aid. Ne Win resigned as president in 1981 but remained head of the BSPP and Burma's most powerful leader.

Military rule. In 1988, large numbers of Burmese demonstrated against the government. They called for an end to one-party rule. Ne Win resigned as head of the BSPP in July. He suggested that economic reforms and multiparty elections might solve the nation's problems. But protests continued into September, at which time the army overthrew the government, replacing it with the newly established State Law and Order Restoration Council (SLORC). Before and after the coup, troops killed thousands of protesters.

In 1989, the SLORC arrested Aung San Suu Kyi, the leader of the National League for Democracy (NLD). She was the daughter of independence leader Aung San. Aung San Suu Kyi was placed under *house arrest* (confined to her home). The SLORC also changed the country's official name to the Union of Myanmar.

The SLORC allowed multiparty elections to take place in May 1990. The NLD won 60 percent of the vote and 80 percent of the seats in the legislature. But many of the elected representatives were imprisoned. The SLORC said it would not allow a transfer of power until a new constitution was written and approved, with a leading role for the military. Although several meetings were held, the revised constitution was never completed.

Aung San Suu Kyi won the 1991 Nobel Peace Prize for her nonviolent struggle for democracy and human rights. The SLORC freed her from house arrest in 1995 but still restricted her travel. The council confined her to her home again from September 2000 to May 2002.

Recent developments. The SLORC changed its name to the State Peace and Development Council (SPDC) in 1997. Economic reforms opened the country to foreign and private businesses, but the economy still suffered from inflation and slow growth. Major nations withheld economic aid because of the SPDC's human rights violations and its failure to open talks with the NLD. The United Nations and its Commission on Human Rights repeatedly criticized Myanmar on these issues.

During much of the late 1900's, rebel groups fought the government and each other. Myanmar's military rulers reached cease-fire agreements with most of the rebels in the 1990's, but fighting continued with several of the largest rebel groups. James F. Guyot

Myasthenia gravis, *MY uhs THEE nee uh GRAV ihs,* is a noncontagious disease characterized by progressive weakness of the skeletal muscles. This weakness increases with physical activity but can be partially relieved by rest. The disease afflicts all age groups and both sexes. However, myasthenia gravis occurs most frequently among women from 15 to 30 years old and men 40 to 70 years old.

Myasthenia gravis affects primarily the skeletal muscles of the face, neck, arms, and legs (see **Muscle**). Symptoms may include a drooping eyelid; difficulty in chewing, swallowing, and talking; fatigue; and general muscle weakness. Diagnosis can be difficult because the early symptoms are slight and may come and go.

Most researchers believe myasthenia gravis results from a defect at a *neuromuscular junction,* the point where a nerve impulse is transmitted to a muscle. Normally, a substance called *acetylcholine* is released from the nerve ending. Acetylcholine becomes attached to acetylcholine receptor molecules on the muscle surface, causing the muscle to contract. In myasthenia gravis, something causes the acetylcholine receptor molecules to become blocked or to decrease in number.

Researchers suspect that myasthenia gravis is an *autoimmune disease.* In such diseases, the body's immune system, which normally attacks harmful bacteria and viruses, attacks the body's own tissues. The immune system of myasthenia gravis patients appears to attack acetylcholine receptor molecules.

With medication, most patients with myasthenia gravis can live almost completely normal lives. Doctors usually treat the disease's symptoms with drugs, either *anticholinesterases* or *immunosuppressives.* Removal of the thymus gland, part of the immune system, may be helpful, particularly during the early stages of the illness. In certain advanced cases, a procedure called *plasmapheresis* may be used. In this procedure, the physician withdraws the patient's blood and filters out the immune substances that may be attacking muscle receptors. The blood is then returned to the patient. Michael S. Hudecki

See also **Thymus**.

Mycenae, *my SEE nee,* was a city in ancient Greece, located 6 miles (10 kilometers) north of Argos in the southern peninsula. German archaeologist Heinrich Schliemann uncovered five royal graves at the site of Mycenae in 1876. This discovery started the study of the Bronze Age on the Greek mainland. These graves, known as the *Shaft Graves,* contained jewels, bronze weapons, and other bronze, gold, and silver objects.

Mycenae was the leading political and cultural center on mainland Greece from about 1400 to 1200 B.C. The Late Bronze Age on the Greek mainland from 1550 to 1100 B.C. is often called the *Mycenaean* period. The city became famous for its royal palace, walled fortress, and beehive-shaped tombs for kings. The tombs can still be seen. The city collapsed during the late 1100's B.C., probably as a result of natural disasters and barbarian invasions. Mycenae never regained its power.

Norman A. Doenges

Mycotoxin, *MY kuh TAHK suhn,* is any one of a number of poisonous chemicals produced by fungi. Mycotoxins form on moldy food crops and other plants, though not all molds produce mycotoxins. Crops most often infected by mycotoxins include peanuts, corn, rice, and wheat. Foods or livestock feed made from contaminated crops can poison people and animals. Meat and milk products from animals that have eaten infected grain also may harm humans. Government agencies in the United States and other countries check mycotoxin levels in food and animal feed.

Dampness promotes the formation of molds that produce mycotoxins. Such molds tend to develop in hot, humid regions, but they can also form in cold climates. During the 1940's, for example, thousands of people in the Soviet Union died from eating grain that was left in snow-covered fields and became contaminated. Proper harvesting, drying, and storage of crops help prevent molds that produce mycotoxins from forming.

Research on a group of mycotoxins called *aflatoxins* has suggested that mycotoxins cause other illnesses besides food poisoning. For example, scientists have discovered that feeding low doses of aflatoxin B1 to laboratory animals can cause liver cancer. As a result, the United Nations International Agency for Research on Cancer classifies this mycotoxin as a substance that can produce human cancer. George S. Bailey

Myelitis, *MY uh LY tihs,* is inflammation of the spinal cord. It is often caused by a virus or other infection. Poliomyelitis, multiple sclerosis, and rabies are forms of myelitis. Symptoms of myelitis diseases often include backache and paralysis. Marianne Schuelein

Myna, *MY nuh,* is the name of several kinds of birds in the starling family. Myna birds are native to India, Myanmar, and other parts of Asia.

The *common myna* is about the size of an American robin. Its colors range from rich wine-brown on the

WORLD BOOK illustration by John Rignall, Linden Artists Ltd.

The talking myna can imitate human speech even better than a parrot can. This glossy, purplish-black bird measures about 12 to 15 inches (30 to 38 centimeters) long.

lower breast to deep black on the head, neck, and upper breast. It has a splash of white on the lower edge of its wings, and its bill and legs are a bright yellow. This myna feeds on plants, insects, and worms. It often builds its nest in crevices of buildings. It is a noisy bird that is common about yards and buildings. It is often seen among chickens or perched on the backs of cattle. People have released the common myna into the wild in many tropical Pacific islands, including Hawaii, where the bird is now abundant.

Talking mynas are sometimes kept as pets. Many imitate the human voice and can talk, sing, and whistle.

Scientific classification. Mynas are in the starling family, Sturnidae. The common myna is *Acridotheres tristis.* The talking myna is *Gracula religiosa.* David M. Niles

Myocardial infarction. See Coronary thrombosis.

Myocarditis, *MY oh kahr DY tihs,* is inflammation of the muscle tissue that forms the heart's wall. This muscle, called the *myocardium,* performs the pumping work of the heart. Mild cases of myocarditis may remain undetected. Severe cases can lead to *heart failure,* in which the heart cannot pump enough blood for the body's needs.

Causes of myocarditis include rejection of transplanted tissue and reactions to viruses and toxic chemicals. But in most cases, the cause is never identified.

Many symptoms of heart disease may accompany myocarditis. These symptoms include weakness, shortness of breath, and accumulation of fluids. Irregular heartbeats and enlargement of the heart may also accompany myocarditis. Doctors can detect these two signs with X rays and *electrocardiograms* (measurements of heart activity). However, to reach a final diagnosis of myocarditis, doctors must examine the heart tissue through a microscope. The tissue is obtained with a *catheter,* a long tube that is inserted into the heart by way of a blood vessel.

There is no established treatment for myocarditis. Many patients recover completely. Others live for years with the condition. Some myocarditis patients die from heart failure, which may occur during periods of acute inflammation of the myocardium or years after inflammation. Toby R. Engel

Myopia. See Nearsightedness.

Myrdal, *MIHR dahl,* **Alva Reimer** (1902-1986), a Swedish diplomat and sociologist, gained fame for promoting nuclear disarmament and world peace. From 1962 to 1973, she headed Sweden's delegation to the United Nations Disarmament Conference in Geneva, Switzerland. Myrdal shared the 1982 Nobel Peace Prize with Alfonso García Robles of Mexico. She was the author of *The Game of Disarmament* (1976) and *War, Weapons, and Everyday Violence* (1977), plus several other books and numerous articles on disarmament.

Myrdal was born in Uppsala, Sweden. She graduated from the University of Stockholm and received a master's degree from the University of Uppsala. Myrdal became Sweden's first woman ambassador. From 1955 to 1961, she served as the country's ambassador to four nations at the same time—Burma, Ceylon (now Sri Lanka), India, and Nepal. Myrdal was a member of Sweden's parliament from 1962 to 1970. She served as minister of disarmament and church affairs in the Swedish Cabinet from 1967 to 1973. Her husband, Gunnar Myrdal, won the 1974 Nobel Prize in economics. The Myrdals were the only married couple to win the Nobel Prize in different categories. James W. Vander Zanden

Myrdal, *MIHR dahl,* **Gunnar** (1898-1987), was a Swedish sociologist and economist. He gained fame for his thorough studies of major world problems. His book *An American Dilemma: The Negro Problem and Modern Democracy* (1944) is considered an outstanding study of race relations in the United States. Myrdal's studies of the economic and social development of underdeveloped nations led him to write *Asian Drama: An Inquiry into the Poverty of Nations* (1968). This book tries to tell why so many people of southern Asia are poor, and what, if anything, can be done about it.

Myrdal shared the 1974 Nobel Prize in economics with Friedrich von Hayek of Austria. His wife, Alva R. Myrdal, was a winner of the 1982 Nobel Peace Prize (see **Myrdal, Alva R.**).

Karl Gunnar Myrdal was born in Gustafs, near Sandviken, Sweden. He received a law degree and a doctor of laws in economics degree from the University of Stockholm. He was minister of commerce in the Swedish Cabinet from 1945 to 1947. He served as executive secretary of the United Nations Economic Commission for Europe from 1947 to 1957. In 1960, he became director of the Institute of International Economic Studies in Stockholm. James W. Vander Zanden

Myrrh, *mur,* is a fragrant gum resin that has been used as a raw material for perfumes since ancient times. It also has been burned as an incense, and used in medicines and in *embalming* (preserving bodies). The Bible says that one of the wise men brought Jesus a gift of myrrh (Matt. 2). Myrrh comes from trees of the genus *Commiphora* found mainly in Saudi Arabia and Ethiopia. The tree discharges the resin from between the outer layers of the bark, and the resin falls to the ground. The perfume ingredient is an oil obtained by heating the resin to produce a vapor, then cooling the vapor.

Patricia Ann Mullen

Myrtle, *MUR tuhl,* is an attractive evergreen shrub or small tree. It grows wild in regions along the Mediterranean Sea and temperate regions of Asia. Some people in the United States cultivate it as an ornamental plant. The myrtle has shiny leaves and fragrant white flowers. The leaves, bark, and blue-black berries are also fra-

The myrtle has shiny leaves and fragrant flowers.

grant. Manufacturers use them in making perfume. The bark is used in tanning industries of southern Europe. Ancient Greeks thought myrtle was sacred to the goddess of love, Aphrodite. They used it in festivals.

The *common periwinkle* is often called *running myrtle.* It has creeping stems and attractive blue flowers.

Scientific classification. Common myrtles belong to the myrtle family, Myrtaceae. Their scientific name is *Myrtus communis.* The common periwinkle is in the dogbane family, Apocynaceae. It is *Vinca minor.* Walter S. Judd

Mysteries, in religion, are secret ceremonies. They may be witnessed or participated in only by people who belong to, or are about to join, the group that practices them. A person joins a group that practices mysteries by undergoing a process of initiation. This process ordinarily includes indoctrination, moral testing, and a rite of purification. Those who are initiated promise never to reveal the group's secret ceremonies and doctrines. Mysteries have been part of many religions. The secrets of early mysteries were so well kept that our knowledge of them is incomplete.

Mysteries were important in ancient Greece and in ancient Rome, beginning in the 600's B.C. One of the most famous Greek mysteries was practiced by a cult in the city of Eleusis near Athens. In early autumn, members of the cult performed what were known as the Eleusinian Mysteries. These mysteries were based on the worship of Demeter—the goddess of fertility. Initiation into the cult included a symbolic cleansing in seawater. Those who joined the cult were promised happiness in an afterlife.

In ancient Rome, mysteries were practiced by members of a cult called *Mithraism.* Mithraism, which was practiced only by men, became popular among Roman soldiers. Cult members worshiped Mithra, the god of light who was originally worshiped by inhabitants of Persia. Initiation into Mithraism included a symbolic washing in the blood of a sacrificial animal.

Other mysteries practiced in ancient times were connected with the worship of the god Dionysus in Greece or the goddesses Cybele and Isis in Rome. Mysteries also became part of religious worship in early Christianity. Christians received the Eucharist in secret rituals. However, after Christianity became the official religion of the Roman Empire in the early 300's, the sacraments became more public. Jill Raitt

Mystery play, a form of Biblical drama, was popular in England from the 1370's until about 1600. Mystery plays were produced and acted by local trade and craft organizations called *guilds.* The term *mystery play* came into use because guilds were sometimes known as *masteries* or *mysteries.* The plays were also called *Corpus Christi plays* because most were presented during the feast of Corpus Christi in late May or June.

Mystery plays dramatized stories from both the Old and New Testaments. Popular subjects included the life of Christ, Adam and Eve, Abraham and Isaac, and Noah and the Flood. Many mystery plays combined biblical scenes with references to local places and events. The plays were staged outdoors, probably on large carts called *pageant wagons.* These wagons were drawn through a town to various places where spectators stood in the street or watched from nearby houses. Each guild in a town was responsible for one episode or play. Mystery plays were presented in cycles of several related dramas. A cycle may have taken one or two days.

The authors of mystery plays, though unknown, were probably members of the guild. Texts of cycles of mystery plays from the towns of Chester, Wakefield, and York have been preserved. Albert Wertheim

Mystic Seaport, a reconstructed waterfront village, is a reminder of maritime life in the days of the great sailing ships. It lies on the Mystic River in Mystic, Conn. For location, see **Connecticut** (political map).

Waterfront buildings and shops typical of the early and mid-1800's stand along Mystic Seaport's cobblestone streets. The *Australia,* the oldest American schooner afloat, and the *Charles W. Morgan,* New England's last wooden whaleship, are moored at the Seaport's docks. Sea Scouts and other youths learn sailing skills aboard these famous old sailing ships. Mystic Seaport also has one of the finest collections of clipper ship models in America. The Marine Historical Association established Mystic Seaport in 1929. Each year, thousands of tourists visit the village. John L. Allen

Mysticism, *MIHS tuh sihz uhm,* is the belief that God or spiritual truths can be known through individual insight, rather than by reasoning or study. All the major religions include some form of mysticism.

A person who has mystical experiences is called a *mystic.* Most mystics find such experiences difficult to describe. Many say they are filled with light, have visions, or hear inner music or voices. Some mystics feel that their spirits fly out of their bodies or become possessed by a higher power. During these experiences, mystics may feel ecstasy or great peace.

Mystics differ in their practice and experiences, even within the same religion. However, most mystics share three basic goals: (1) knowledge of a spiritual reality that exists beyond the everyday world, (2) spiritual union with some higher power, and (3) freedom from selfish needs and worldly desires. To attain these goals, most mystics undergo some form of self-discipline. For example, they may isolate themselves from material comforts and other people. In addition, their discipline may involve extremes of mental and physical activity. Buddhist mystics may meditate for hours or even days without moving. Jews who belong to the Hasidic group often shout and twist their bodies while praying. Some members of the Islamic Sufi sect go into a trance as they perform a whirling dance.

Mysticism has played a prominent role in many religions. Devout Buddhists and Hindus may dedicate their lives to the mystical search for direct spiritual experience. Christian mystics have included several Roman Catholic saints and the Quakers. In Islam, Judaism, and other religions that emphasize the role of a supreme God, mystics may believe that their experiences result from divine actions. In religions in which many gods are worshiped, such as Hinduism and Taoism, mystics may attribute their insights to their own individual efforts.

The gods and goddesses of mythology served many functions. The Greeks worshiped Athena, *left,* as the goddess of wisdom and warfare. Xipe Tótec, *center,* was the Aztec god of vegetation. The ancient Egyptian god Anubis, *right,* helped judge the souls of dead people in the underworld.

Mythology

Mythology. People have always tried to understand why certain things happen. For example, they have wanted to know why the sun rises and sets and what causes lightning. They have also wanted to know how the earth was created and how and where humanity first appeared.

Today, people have scientific answers and theories for many such questions about the world around them. But in earlier times—and in some parts of the world today—people lacked the knowledge to provide scientific answers. They therefore explained natural events in terms of stories about gods, goddesses, and heroes. For example, the Greeks had a story to explain the existence of evil and trouble. The Greeks believed that at one time the world's evils and troubles were trapped in a box. They escaped when the container was opened by Pandora, the first woman. Such stories are known as *myths,* and the study of myths is called *mythology.*

In early times, every society developed its own myths, which played an important part in the society's religious life. This religious significance has always separated myths from similar stories, such as folk tales and legends. The people of a society may tell folk tales and legends for amusement, without believing them. But they usually consider their myths sacred and completely true.

C. Scott Littleton, the contributor of this article, is Professor of Anthropology at Occidental College and the author of The New Comparative Mythology.

Most myths concern *divinities* (divine beings). These divinities have *supernatural* powers—powers far greater than any human being has. But in spite of their supernatural powers, many gods, goddesses, and heroes of mythology have human characteristics. They are guided by such emotions as love and jealousy, and they experience birth and death. A number of mythological figures even look like human beings. In many cases, the human qualities of the divinities reflect a society's ideals. Good gods and goddesses have the qualities a society admires, and evil ones have the qualities it dislikes.

By studying myths, we can learn how different societies have answered basic questions about the world and the individual's place in it. We study myths to learn how a people developed a particular social system with its many customs and ways of life. By examining myths, we can better understand the feelings and values that bind members of society into one group. We can compare the myths of various cultures to discover how these cultures differ and how they resemble one another. We can also study myths to try to understand why people behave as they do.

For thousands of years, mythology has provided material for much of the world's great art. Myths and mythological characters have inspired masterpieces of architecture, literature, music, painting, and sculpture.

What myths are about

Most myths can be divided into two groups—*creation myths* and *explanatory myths.* Creation myths try to explain the origin of the world, the creation of human beings, and the birth of gods and goddesses. All early societies developed creation myths. Explanatory myths try to explain natural processes or events. The Norse, who lived in medieval Scandinavia, believed that the god Thor made thunder and lightning by throwing a hammer at his enemies. The ancient Greeks believed that the lightning bolt was a weapon used by the god Zeus. Many societies developed myths to explain the formation and characteristics of geographic features, such as rivers, lakes, and oceans.

Some explanatory myths deal with illness and death. Many ancient societies—as well as some primitive present-day societies—believed that a person dies because of some act by a mythical being. The people of the Trobriand Islands in the Pacific Ocean believed that men and women were immortal when the world was new. When people began to age, they swam in a certain lagoon and shed their skin. They quickly grew new skin, renewing their youth. One day, a mother returned from the lagoon with her new skin. But her unexpected youthful appearance frightened her little daughter. To calm the child, the mother returned to the lagoon, found her old skin, and put it back on. From then on, according to this myth, death could not be avoided.

Some myths, through the actions of particular gods and heroes, stress proper behavior. The ancient Greeks strongly believed in moderation—that nothing be done in excess. They found this ideal in the behavior of Apollo, the god of purity, music, and poetry. Myths about national heroes also point up basic moral values. The story about young George Washington's confession that he had cut down his father's cherry tree has no basis in fact. Yet many people like to believe the story because it emphasizes the quality of honesty.

Mythical beings fall into several groups. Many gods and goddesses resemble human beings, even though they have supernatural powers. These gods and goddesses were born, fell in love, fought with one another, and generally behaved like their human worshipers. These divinities are called *anthropomorphic,* from two Greek words meaning *in the shape of man.* Greek mythology has many anthropomorphic divinities, including Zeus, who was the most important Greek god.

Another group of mythical beings includes gods and goddesses who resemble animals. These characters are called *theriomorphic,* from two Greek words meaning *in the shape of an animal.* Many theriomorphic beings appear in Egyptian mythology. For example, the Egyptians sometimes represented their god Anubis as a jackal or a dog.

A third group of mythical beings has no specific name. These beings were neither completely human nor completely animal. An example is the famous sphinx of Egypt, which has a human head and a lion's body.

Human beings play an important part in mythology. Many myths deal with the relationships between mortals and divinities. Some mythical mortals have a divine father and a mortal mother. These human characters are called *heroes,* though they do not always act heroically in the modern sense. Most stories about heroes are called *epics* rather than myths, but the difference between the two is not always clear.

Mythical places. Many myths describe places where demons, gods and goddesses, or the souls of the dead live. Most of these places are in the sky or on top of a high mountain. The people believed that the divinities could see everything, and so they located them in a place higher than mortals could reach.

Mythical places exist in the mythologies of most peoples. Perhaps the most sacred place in Japanese mythology is Mount Fuji, the tallest mountain in Japan. During part of their history, the Greeks believed their divinities lived on a mythical Mount Olympus that was separate from the visible Mount Olympus in northern Greece.

The Greeks also believed in mythical places beneath the ground, such as Hades, where the souls of the dead lived. The Norse believed in Hel, an underground home for the souls of all dead persons, except those killed in battle. The souls of slain warriors went to Valhalla, which was a great hall in the sky. The Eskimos believe that their sea goddess, Sedna, lives in a world under the ocean.

Mythical symbols. In their mythologies, people used many symbols to help explain the world. The Greeks symbolized the sun as the god Helios driving a flaming chariot across the sky. The Egyptians represented the sun as a boat.

Detail of a painting on papyrus (900's B.C.); Egyptian Museum, Cairo (Walter Sanders, *LIFE* Magazine © Time Inc.)

The separation of the earth from the sky is described in many mythologies. According to Egyptian mythology, the god Shu, *standing center,* raised the sky goddess, Nut, away from her husband, the earth god, Geb, *lying down.* Nut's body thus formed the heavens.

Animals, human beings, and plants have all stood for ideas and events. Some peoples adopted the serpent as a symbol of health because they believed that by shedding its skin, the serpent became young and well again. The Greeks portrayed Asclepius, the god of healing, holding a staff with a serpent coiled around it. Today, that staff symbolizes the medical profession. It is often confused with the *caduceus* of the god Mercury, which has two snakes coiled around it. In Babylonian mythology, the hero Gilgamesh searched for a special herb that made anyone who ate it immortal. Plants can also have opposite meanings. In the Bible, Adam and Eve ate the forbidden fruit and lost their immortality.

Comparing myths. We study the similar myths of various societies by comparing them to one another. We can compare these myths on the basis of their generic, genetic, or historical relationships.

Generic relationships among myths are based on the way people react to common features in their environment. For example, the Maoris of New Zealand and the ancient Greeks both had myths that described how the earth became separated from the sky.

Genetic relationships. A large society may develop a particular myth. Then, for some reason, the society breaks up into several separate societies, each of which develops its own version of the myth. These myths have a genetic relationship.

Myths about the Greek god Zeus and the ancient Indian god Indra have a genetic relationship. The two gods resemble each other in many ways. For example, each is a sky god, and each uses a lightning bolt as his chief weapon. These similarities can be explained by the fact that the ancient Greeks and the people of ancient India descended from a common culture, the Indo-European community. The Indo-Europeans lived several thousand years ago in the area north of the Black Sea, in southeastern Europe. This culture worshiped a warrior god who ruled the sky. One group of Indo-Europeans migrated westward to what is now Greece. There, they developed a sky god who became known as Zeus. Another group of Indo-Europeans, the Aryans, migrated southward into northern India. They developed the warlike sky god Indra.

Historical relationships appear when similar myths develop among cultures that do not share a common origin. For instance, many ancient Near and Middle Eastern societies had a myth in which several generations of sons overthrew their fathers, who ruled as gods or kings. Variations of this myth appeared in Greece and Iran, among the Hittites in what is now Turkey, and among the Phoenicians in what is now Lebanon. Many scholars believe all versions of the myth came from a Babylonian myth dating from about 2000 B.C.

In the 700's B.C., the Greek poet Hesiod wrote a long poem called the *Theogony.* In this poem, Hesiod described the origin of the world and the history of the gods. The *Theogony* contains Greek myths that have generic, genetic, and historical relationships with myths of other cultures. For example, Hesiod describes how the earth became separated from the sky. This myth is generically related to a similar Maori myth. Zeus, a major figure in the *Theogony,* genetically resembles the Indian god Indra. Hesiod also wrote about successive generations of Greek gods being overthrown by their sons. This myth is historically related to similar myths in other cultures of the ancient Near and Middle East.

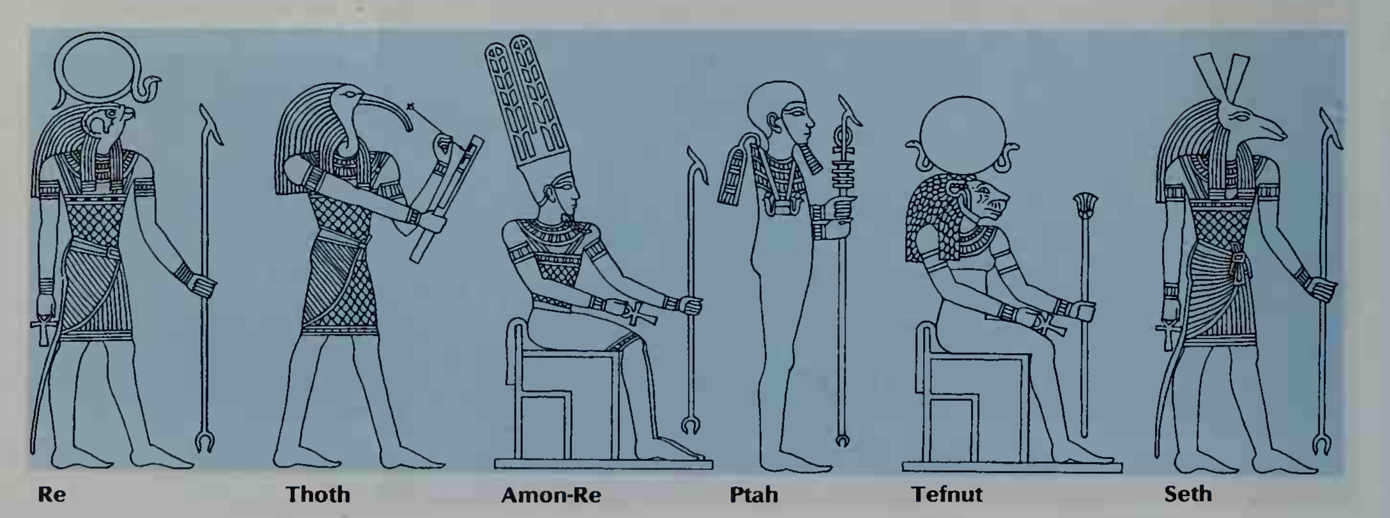
Oil painting on canvas by N. A. Abilgaard; Royal Museum of Fine Arts, Copenhagen, Denmark

The creation of life is the subject of many myths. According to a Teutonic myth, the giant Ymir and the cow Audhumla became the first living things. They were born out of melting ice. Audhumla's milk fed Ymir. As the cow licked the ice for its salt, she freed the body of Buri, a second giant. Buri was the ancestor of the first race of gods.

The Nile River plays an important part in Egyptian mythology. As the Nile flows northward through Egypt, it creates a narrow ribbon of fertile land in the midst of a great desert. The sharp contrast between the fertility along the Nile and the wasteland of the desert became a basic theme of Egyptian mythology. The creatures that live in the Nile or along its banks became linked with many gods and goddesses.

The Great Ennead. The earliest information we have about Egyptian mythology comes from *hieroglyphics* (picture writings) on the walls of tombs, such as the burial chambers in pyramids. These "pyramid texts" and other documents tell us that from about 3200 to 2250 B.C. the Egyptians believed in a family of nine gods. This family became known as the *Great Ennead,* from the Greek word *ennea,* meaning *nine.* The nine gods of the Great Ennead were Atum, Shu and Tefnut, Geb and Nut, Osiris, Isis, Nephthys, and Horus.

The term *Ennead* later came to include other deities as well. One of these deities was Nun, who symbolized a great ocean that existed before the creation of the earth and the heavens. Another of these deities was the sun god, called Re or Ra. The Egyptians considered Re both the ruler of the world and the first divine pharaoh.



The first god of the Great Ennead was Atum. He was sometimes identified with the setting sun. Atum also represented the source of all gods and all living things. Re created a pair of twins, Shu and his sister, Tefnut. Shu was god of the air, which existed between the sky and the earth. Tefnut was goddess of the dew. Shu and Tefnut married and also produced twins, Geb and his sister, Nut. Geb was the earth god and the pharaoh of Egypt. Nut represented the heavens. Geb and Nut married, but the sun god Re opposed the match and ordered their father, Shu, to raise Nut away from Geb into the sky. Shu's action separated the heavens from the earth. Nut had speckles on her body, and the speckles became the stars.

The Osiris myth. In spite of their separation, Geb and Nut had several children. These included three of the most important divinities in Egyptian mythology—Osiris, Isis, and Seth.

Important divinities in Egyptian mythology

The ancient Egyptians portrayed many of their gods and goddesses with human bodies and the heads of birds or other animals. The divinities held or wore objects symbolizing their power. For example, the god Osiris held a scepter and a whip, which represented the authority of gods and divine pharaohs.

WORLD BOOK illustrations by George Suyeoka

Originally, Osiris may have been god of vegetation, especially of the plants that grew on the rich land along the Nile. The goddess Isis may have represented female fertility. Seth was god of the desert, where vegetation withers and dies from lack of water.

Geb retired to heaven. Osiris then became pharaoh and took Isis as his queen. Seth grew jealous of Osiris's position and killed him. In some versions of this myth, Seth cut Osiris's body into pieces, stuffed the pieces into a box, and set the box afloat on the Nile. Isis refused to accept her husband's death as final. She searched for Osiris's remains with the aid of her sister Nephthys and several other gods and goddesses. Isis finally found the remains of Osiris. With the help of other divinities, she put the body together, restoring Osiris to life. Osiris then became god of the afterlife.

Seth had become pharaoh of Egypt after killing Osiris. But Horus, son of Osiris and Isis, then overthrew Seth and became pharaoh. Thus, the forces of vegetation and creation—symbolized by Osiris, Isis, and Horus—triumphed over the evil forces of the desert, symbolized by Seth. But more important, Osiris had cheated death. The Egyptians believed that if Osiris could triumph over death, so could human beings.

Other Egyptian divinities included Hathor, Horus's wife; Anubis; Ptah; and Thoth. Hathor became the protector of everything feminine. Anubis escorted the dead to the entrance of the afterworld and helped restore Osiris to life. The Egyptians also believed that Anubis invented their elaborate funeral rituals and burial procedures. Ptah invented the arts. Thoth invented writing and magical rituals. He also helped bring Osiris back to life.

Many animals appear in Egyptian mythology. The falcon and the scarab, or dung beetle, were two animals that symbolized the sun god. The Egyptians considered both the cat and the crocodile as divine.

Between 1554 and 1070 B.C., various local divinities became well known throughout ancient Egypt. Some of them became as important as the gods and goddesses of the Ennead. The greatest of these gods was Amon. His *cult* (group of worshipers) originally centered in Thebes. In time, Amon became identified with Re, and was frequently known as Amon-Re. Amon-Re became perhaps the most important Egyptian divinity.

The influence of Egyptian mythology. The divinities of ancient Egypt and the myths about them had great influence on the mythologies of many later civilizations. Egyptian religious ideas may also have strongly affected the development of Judaism and Christianity.

During the 1300's B.C., the pharaoh Amenhotep IV chose Aten as the only god of Egypt. Aten had been a little-known god worshiped in Thebes. Amenhotep was so devoted to the worship of Aten that he changed his own name to Akhen*aten*. The Egyptians stopped worshiping Aten after Akhenaten died. However, some scholars believe the worship of this one divinity lingered among the people of Israel, who had settled in Egypt, and became an important part of the religion that was developed by the Israelite leader Moses. These scholars have suggested that the Jewish and Christian belief in one God may come from the cult of Aten. See **Akhenaten**.

Detail of a papyrus scroll (about 1025 B.C.); Metropolitan Museum of Art, New York City, Museum Excavations and Rogers Fund, 1930

Osiris, Egyptian god of the afterlife, judged the souls of the dead. In this scene, the jackal-headed god Anubis uses a balance scale to weigh a human heart, in the left pan, against objects representing truth and justice, in the right pan. Osiris, sitting at the right, makes the judgment.

Greek mythology

The earliest record of Greek mythology comes from clay tablets dating back to the Mycenaean civilization, which reached its peak between 1400 and 1200 B.C. This civilization consisted of several cities in Greece, including Mycenae. The clay tablets describe the chief Mycenaean god as Poseidon. He reappeared in later Greek mythology as a major figure. The god Zeus, who later became the chief god in Greek mythology, played a lesser part in Mycenaean myths.

About 1200 B.C., the Mycenaean civilization fell. During the 1100's B.C., Dorians from northwestern Greece moved into lands that had been held by the Mycenaeans. In the next 400 years, known as the Dark Age of ancient Greece, the Dorian and Mycenaean mythologies combined, helping form classical Greek mythology. See **Dorians.**

The basic sources for classical Greek mythology are three works that date from about the 700's B.C.: the *Theogony* by Hesiod and the *Iliad* and the *Odyssey,* attributed to Homer. Hesiod and Homer rank among the greatest poets of ancient Greece. The *Theogony* and the *Iliad* and *Odyssey* contain most of the basic characters and themes of Greek mythology.

The creation myth. The *Theogony* includes the most important Greek myth—the myth that describes the origin and history of the gods. According to the *Theogony,* the universe began in a state of emptiness called *Chaos.* The divinity Gaea, or Earth, arose out of Chaos. She immediately gave birth to Uranus, who became king of the sky. Gaea mated with Uranus, producing children who were called the *Titans.*

Uranus feared his children and confined them within the huge body of Gaea. Gaea resented the imprisonment of her children. With Cronus, the youngest Titan, she plotted revenge. Using a sickle provided by Gaea, Cronus attacked Uranus and made him *impotent* (unable to breed children). Cronus then freed the Titans from inside Gaea. Because Uranus was impotent, Cronus became king of the sky. During his reign, the work of creating the world continued. Thousands of divinities were born, including the gods or goddesses of death, night, the rainbow, the rivers, and sleep.

Cronus married his sister Rhea, who bore him three daughters and three sons. But Cronus feared that he, like Uranus, would be deposed by his children. He therefore swallowed his first five children as soon as they were born. To save her sixth child, Zeus, Rhea tricked Cronus into swallowing a stone wrapped in baby clothes. Rhea then hid the infant on the island of Crete. After Zeus grew up, he returned to challenge his father. He tricked Cronus into drinking a substance that made him vomit his children. The children had grown into adults while inside their father. Zeus then led his brothers and sisters in a war against Cronus and the other Ti-

Detail of a painting (300's B.C.) on a Greek vase; the Louvre, Paris

The Greek gods fought the giants after the gods had defeated the Titans. The giants were born from the blood of Uranus, father of the Titans. In this scene, Zeus, *center,* strikes at the giants with a thunderbolt. Hercules, *kneeling,* aims an arrow at a giant. Athena, *lower left,* attacks another giant with her spear.

The Building of the Trojan Horse (about 1760), an oil painting by Giovanni Domenico Tiepolo; Wadsworth Atheneum, Hartford, Conn., Ella Gallup Sumner and Mary Catlin Sumner Collection

The Greeks built the Trojan horse, hid several soldiers inside, and left it outside the walls of Troy. The Trojans believed the horse was a gift from the Greeks and pulled it into the city. After dark, the soldiers sneaked out and opened the city gates for the Greek army.

tans. Zeus and his followers won the war. They exiled the Titans in chains to Tartarus, a dark region deep within the earth. The victorious gods and goddesses chose Zeus as their ruler and agreed to live with him on Mount Olympus. The divinities who lived on Olympus became known as *Olympians.*

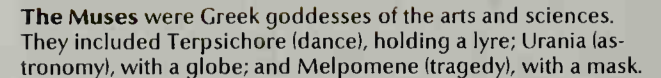
Greek divinities can be divided into several groups. The earliest group was the Titans, led by Cronus. The most powerful group was the Olympians. Several ranks of divinities existed among the Olympians. The top rank consisted of six gods and six goddesses. The gods were Zeus, ruler of all divinities; Apollo, god of music, poetry, and purity; Ares, god of war; Hephaestus, blacksmith for the gods; Hermes, messenger for the gods; and Poseidon, god of earthquakes and the ocean. The goddesses were Athena, goddess of wisdom and war; Aphrodite, goddess of love; Artemis, the twin sister of Apollo and goddess of hunting; Demeter, goddess of fertility; Hera, sister and wife of Zeus; and Hestia, goddess of the hearth.

Three important gods became associated with the 12 Olympians. They were Hades, ruler of the underworld and brother of Zeus; Dionysus, god of wine and wild behavior; and Pan, god of the forest and pastures.

There were several groups of minor divinities in Greek mythology. Beautiful maidens called *nymphs* guarded various parts of nature. Nymphs called *dryads* lived in the forest, and nymphs called *Nereids* lived in the sea. Three goddesses called *Fates* controlled the destiny of every man. The *Muses* were nine goddesses of various arts and sciences. All these divinities became the subjects of specific myths and folk tales.

Greek mythology also has a number of partly mortal, partly divine beings called *demigods.* Heracles (called Hercules by the Romans) probably ranked as the most important demigod. Heracles symbolized strength and physical endurance. Another demigod, Orpheus, became known for his beautiful singing.

Nearly all the Greek gods, goddesses, demigods, and other divinities became the subjects of cults. Many cults became associated with cities. People of Delphi, famous for its *oracle* (prophet), especially worshiped Apollo (see **Delphi**). People of Athens looked to Athena as their protector. Ephesus became the center of the cult of Artemis. The Temple of Artemis in Ephesus was one of the Seven Wonders of the Ancient World (see **Seven Wonders of the Ancient World**).



Greek heroes became almost as important as the divinities in Greek mythology. Heroes were largely or entirely mortal. They were born, grew old, and died. But they still associated with the divinities. Many heroes claimed gods as their ancestors.

Most Greek heroes and heroines can be divided into two main groups. The first group came before the Trojan War, and the second group fought in the war.

The most famous heroes before the Trojan War include Jason, Theseus, and Oedipus. Jason led a band of heroes called the Argonauts on a search for the fabulous Golden Fleece, the pure gold wool of a sacred ram. Theseus killed the Minotaur, a monster with the body of a man and the head of a bull. Oedipus, the king of Thebes, unknowingly killed his father and married his mother. Oedipus' story has been popular with artists and writers for more than 2,000 years.

Detail of a marble relief from a Greek coffin, the Louvre, Paris

The Muses were Greek goddesses of the arts and sciences. They included Terpsichore (dance), holding a lyre; Urania (astronomy), with a globe; and Melpomene (tragedy), with a mask.

Painting (420 to 410 B.C.) on a Greek cup; courtesy of the Museum of Fine Arts, Boston, Pierce Fund

The centaurs, in Greek mythology, were part human and part horse. In one myth, pictured here, a centaur attempted to attack Deianira, the wife of Hercules. But Hercules rescued her.

The Trojan War was fought between Greece and the city of Troy. The war began after Helen, wife of the king of Sparta, fled to Troy with Paris, son of the Trojan king. The Greeks organized an army to attack Troy and bring Helen back to Greece. Our knowledge of the war comes chiefly from the *Iliad* and *Odyssey.*

The Greek heroes who participated in the Trojan War included Agamemnon, the commander in chief; Menelaus, Helen's husband; and Odysseus (Ulysses in Latin), the clever general who formed a plan that finally led to Troy's defeat. Achilles was the most famous Greek warrior, and the major Trojan heroes were Hector and Paris. The gods and goddesses participated in the war almost as much as the heroes. Nearly all the divinities sided with the Greeks. The major exception was the goddess of love, Aphrodite.

Greek and Roman divinities

Many gods and goddesses of Greek mythology held similar positions in Roman mythology. For example, each mythology had a goddess of love. The Greeks called her Aphrodite. The Romans called her Venus. The table below lists the most important Greek and Roman divinities.

Greek	Roman	Position
Aphrodite	Venus	Goddess of love
Apollo	Apollo	God of light, medicine and poetry
Ares	Mars	God of war
Artemis	Diana	Goddess of hunting and childbirth
Asclepius	Aesculapius	God of healing
Athena	Minerva	Goddess of crafts, war, and wisdom
Cronus	Saturn	In Greek mythology, ruler of the Titans and father of Zeus; in Roman mythology, also the god of agriculture
Demeter	Ceres	Goddess of growing things
Dionysus	Bacchus	God of wine, fertility, and wild behavior
Eros	Cupid	God of love
Gaea	Terra	Symbol of the earth and mother and wife of Uranus
Hephaestus	Vulcan	Blacksmith for the gods and god of fire and metalworking
Hera	Juno	Protector of marriage and women. In Greek mythology, sister and wife of Zeus; in Roman mythology, wife of Jupiter
Hermes	Mercury	Messenger for the gods; god of commerce and science; and protector of travelers, thieves, and vagabonds
Hestia	Vesta	Goddess of the hearth
Hypnos	Somnus	God of sleep
Pluto, or Hades	Pluto	God of the underworld
Poseidon	Neptune	God of the sea. In Greek mythology, also god of earthquakes and horses
Rhea	Ops	Wife and sister of Cronus
Uranus	Uranus	Son and husband of Gaea and father of the Titans
Zeus	Jupiter	Ruler of the gods

To many people, Roman mythology largely seems a copy of Greek mythology. The Romans had come into contact with Greek culture during the 700's B.C., and afterward some of their divinities began to reflect the qualities of Greek gods and goddesses. But before that time, the Romans had developed their own mythology. In fact, many of the basic similarities between Roman and Greek mythology can be traced to the common Indo-European heritage shared by Rome and Greece.

Roman divinities. Before the Romans came into contact with Greek culture, they worshiped three major gods—Jupiter, Mars, and Quirinus. These gods are known as the *archaic triad,* meaning *old group of three.* Jupiter ruled as god of the heavens and came to be identified with Zeus. Mars was god of war. He occupied a much more important place in Roman mythology than did Ares, the war god in Greek mythology. Quirinus apparently represented the common people. The Greeks had no similar god.

By the late 500's B.C., the Romans began to replace the archaic triad with the *Capitoline triad*—Jupiter, Juno, and Minerva. The triad's name came from the Capitoline Hill in Rome, on which stood the main temple of Jupiter. In the new triad, Jupiter remained the Romans' chief god. They identified Juno with the Greek goddess Hera and Minerva with Athena.

Between the 500's and 100's B.C., additional Roman mythological figures appeared, nearly all based on Greek divinities. These Roman divinities, with their Greek names in parentheses, included Bacchus (Dionysus), Ceres (Demeter), Diana (Artemis), Mercury (Hermes), Neptune (Poseidon), Pluto (Hades), Venus (Aphrodite), and Vulcan (Hephaestus).

In addition to Greek-inspired divinities, the Romans worshiped many native gods and goddesses. These included Faunus, a nature spirit; Februus, a god of the underworld; Pomona, goddess of fruits and trees; Terminus, god of boundaries; and Tiberinus, god of the Tiber River.

Romulus and Remus. In their mythology, the Romans—unlike the Greeks—tried to explain the founding and history of their nation. Thus, the Romans came to consider their divinities as historical persons. The best example of this historical emphasis is the story of Romulus and Remus, the mythical founders of Rome.

The ancient Romans believed that Romulus and Remus were twins born of a mortal mother and the war god, Mars. Soon after their birth, they were set afloat in a basket on the Tiber River. A she-wolf found the babies and cared for them. Finally, a shepherd discovered the twins and raised them to adulthood.

Romulus and Remus decided to build a city at the spot on the Tiber where the wolf had found them. In a quarrel, Romulus or one of Romulus' followers killed Remus. Romulus then founded Rome, supposedly in 753 B.C. The Romans believed that Romulus became the city's first king and established most of the Roman political institutions.

The seven kings. According to Roman mythology, Romulus was the first of seven kings who ruled Rome from its founding until the early 500's B.C. The kings after Romulus were Numa Pompilius, Tullus Hostilius, Ancus Marcius, Lucius Tarquinius Priscus, Servius Tullius, and Lucius Tarquinius Superbus. The seven kings became known for various achievements. For example, Numa started many of Rome's basic religious institutions. Tullus Hostilius was a warlike king who conquered the Albans, an Italian tribe that lived southeast of Rome.

There is little evidence that the seven early kings of Rome ever existed or that any of the events connected with their reigns ever took place. Some scholars believe these kings probably originated as divinities, whom the Romans converted into historical figures. The kings and the gods have many similarities. For example, Romulus resembles Jupiter because both were primarily rulers, not military leaders. Tullus Hostilius resembles Mars.

The *Aeneid.* During the 200's B.C., the Romans tried to relate the origins of their divinities to Greek myths. About the time of the birth of Christ, the Roman poet Virgil wrote an epic poem called the *Aeneid.* Virgil modeled the *Aeneid* on the *Iliad* and the *Odyssey* by Homer. Virgil tried to connect the origins of Rome to the events that followed the fiery destruction of Troy by the Greeks.

The *Aeneid* traces the wanderings of the Trojan hero Aeneas, who escaped unharmed from the burning city. He stopped for a time in the city of Carthage in northern Africa. There, he rejected the love of Dido, queen of Carthage. He then sailed for Italy and, in time, landed near the mouth of the Tiber River. After many adventures, Aeneas founded a town. Aeneas' son, Ascanius, later moved the town to Alba Longa, where Romulus and Remus were born. Virgil thus connected the founding of Rome with the Trojan War, a significant event in Greek mythology. See **Aeneid**.

Romulus and Remus were the mythical founders of Rome. A wolf nursed the twins, *lower left,* after they were abandoned as babies. One of the shepherds, *above,* later found the boys.

Mythology of the Pacific Islands

Many thousands of islands lie scattered throughout the Pacific Ocean. A rich tradition of myths and mythological figures flourished among the numerous cultures of the islands until the late 1800's, when many of the people became Christians. Some non-Christian cultures have retained their traditional mythologies. In addition, some Christians have kept parts of their native mythologies. See **Pacific Islands.**

Creation myths. Some cultures of the Pacific Islands believed that heaven and the earth always existed. These cultures therefore developed no myths about the creation of the world. Many cultures also assumed that the ocean, which plays such a vital part in Pacific Islands life, always existed.

Some island cultures believed that gods created the world. Other cultures thought the world developed slowly from a great emptiness. According to this myth, the earth and the sky first existed close together and then separated. Several versions of the myth explain how this separation occurred. One example comes from the Maoris of New Zealand. The Maoris have a myth in which the sky, Rangi, loved the earth, Papa. Rangi and Papa gave birth to many gods, who became crushed in the embrace of their parents. In order to survive, the gods separated the earth and the sky, so that life could exist between them.

Pacific Islands divinities. Many similarities existed among the major divinities of the Pacific Islands cultures. Many islanders worshiped a god called Tangaroa. In the New Hebrides (now Vanuatu), he and another divinity ruled the world jointly. In Tahiti, he was a human being who became a divinity.

The most famous demigod among the islands of Polynesia was Maui. According to some myths, Maui created the Hawaiian Islands by fishing them up from the ocean. One of the Hawaiian Islands is named after him. The Polynesians also credited this demigod with teaching human beings how to make fire and do other useful things.

The people of the Pacific Islands believed in the existence of little people similar to the dwarfs and elves of European folklore. The Hawaiians called these people the *menehune.* Pacific Islanders believed the menehune were responsible for events that could not otherwise be explained. For example, if a worker finished a job faster than expected, the menehune was given the credit for the worker's unexplainable speed. If a wall was so old that nobody could remember who built it, the people decided the menehune must have put it up.

Wood sculpture with beaten bark cloth, 22 ½ inches (57 centimeters) high; Museum of Man, Paris

The fire goddess Pele was worshiped in many parts of Polynesia. The Hawaiians believed she lived in the volcano Kilauea. When the goddess became angry, the volcano erupted.

Mana and taboo. The idea of *mana* was important in Pacific Islands mythology. The islanders considered mana an impersonal, supernatural force that flowed through objects, persons, and places. A person who succeeded at a difficult task had a large amount of mana. However, a warrior's defeat in battle showed that the warrior had lost mana. The islanders believed certain animals, persons, and religious objects had so much mana that contact with them was dangerous for ordinary people. These mana-filled beings and objects were thus declared *taboo* (forbidden to touch). The islanders believed a person who touched a taboo object would suffer injury or even death. See **Taboo.**

African mythology

A wide variety of mythologies has developed among the many peoples that live in Africa south of the Sahara. Some of these mythologies are simple and primitive. Others are elaborate and complicated.

The majority of African peoples worship prominent features in nature, such as mountains, rivers, and the sun. Most of these peoples believe that almost everything in nature contains a spirit. Some spirits are friendly, but others are not. Spirits may live in animals, plants, or lifeless objects. Worshipers pray or offer gifts to the spirits to gain their favor and obtain particular benefits from them.

Ancestor worship forms part of many African mythologies. Many Africans believe that, after death, the souls of their ancestors are reborn in living things or in objects. For example, the Zulus refuse to kill certain kinds of snakes because they believe the souls of their ancestors live in those snakes.

Magic plays a major role in the traditional religions of Africa. Priests have great influence among many African peoples because the priests are believed to have magical powers. Many Africans wear charms to protect themselves from harm.

According to several African mythologies, many divinities live in temporary homes on the earth called *fetishes* (see **Fetish**). Fetishes vary from simple stones to beautifully carved images. Some African groups believe that fetishes protect them from evil spells and bring them good luck.

The Ashantis make up the largest native group in Ghana, a small country in western Africa. In many ways, the mythology of the Ashantis illustrates African mythology in general.

Many Ashantis believe that a supreme god called Nyame created the universe. Nyame heads a large group of divinities, most of whom descended from him. Some of these divinities serve as protectors of specific villages or regions. Others represent geographic features. The Ashantis regard rivers as the most sacred geographic feature. They also associate many divinities with specific occupations and crafts, such as farming and metalworking.

Among the Ashanti divinities, only the earth goddess lacks a specific fetish. The Ashantis believe the earth itself is the fetish of the earth goddess. A group of priests supervises the worship of fetishes. The Ashantis believe that their priests possess certain special powers. For example, according to the Ashantis, the priests can persuade a fetish to speak through the lips of a human agent called a *medium*. A priest usually serves as the medium for the fetish. For more information on African mythology, see the *Religions* section of the article **Africa**.

Fetish figures like this one of the Songe people of Congo (Kinshasa) are used to protect village property. Animal skin, beads, and other materials are added to increase a figure's powers.

Celtic mythology

The Celts were an ancient people of Indo-European origin. Most Celts lived in what is now southwestern Germany until about 500 B.C. They then began settling throughout western Europe, especially in England, Ireland, Scotland, and Wales. See **Celts**.

Much of our information on Celtic mythology is about mythical characters and events in Ireland. During the Middle Ages, Irish monks preserved many ancient Celtic myths in several collections of manuscripts. The most important collection of manuscripts is the *Lebor Gabala* (*Book of Conquests*), which traces the mythical history of Ireland. Another important collection of manuscripts, *The Mabinogion,* comes from Wales. The first four stories in this collection are called the "Four Branches of the Mabinogi." These stories describe the mythical history of Britain. The Welsh myths show a much stronger Christian influence than do the Irish myths. In addition, the Welsh myths tend to emphasize human characters. The Irish myths deal more with divinities.

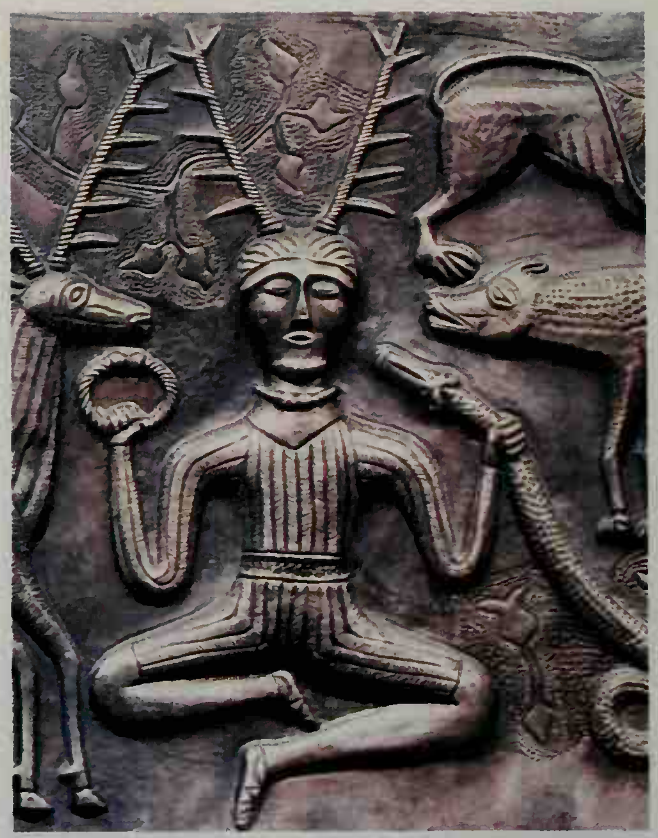
The Irish cycles. A great deal of Irish Celtic mythology concerns three important *cycles* (series of related stories). These cycles are (1) the mythological cycle, (2) the Ulster cycle, and (3) the Fenian cycle.

The mythological cycle, the oldest cycle, is preserved in the *Lebor Gabala*. The cycle describes the early settlement of Ireland through a succession of invasions by five supernatural races. The most important race was the Tuatha De Danann, or People of the Goddess Danu. The Tuatha De Danann was the fourth of the five invading races. They defeated two other races, the Firbolgs and the Fomoirans, and were in turn defeated by the Sons of Mil, also called the Milesians. The Tuatha De Danann were the source of most of the divinities that the Irish people worshiped before they became Christians in the A.D. 400's.

The Ulster cycle centers on the court of King Conchobar at Ulster, probably about the time of Christ. The stories deal with the adventures of Cuchulainn, a great Irish hero who can also be considered a demigod. In some ways, he resembled the Greek hero Achilles. But unlike Achilles and other Greek heroes, Cuchulainn had many supernatural powers. For example, he could spit fire in battle. He was also a magician and poet.

Many stories about Cuchulainn appear in the Ulster cycle. Probably the best known is *The Cattle Raid of*

Cooley. In this story, Queen Mave of Connaught ordered a raid on Ulster to capture a famous brown bull. Cuchulainn single-handedly fought off the invaders until the queen's forces finally captured the bull. However, the Ulster warriors led by King Conchobar came to Cuchulainn's aid and drove the invaders out of the country. Queen Mave plotted revenge against Cuchulainn and several years later used supernatural means to cause his death. See **Cuchulainn.**



The Fenian cycle describes the deeds of the hero Finn MacCool and his band of warriors known as the *Fianna.* Finn and the Fianna were famous for their great size and strength. In addition, Finn was known for his generosity and wisdom. Although divine beings and supernatural events play a part in these stories, the central characters are human. Some scholars believe the events in the Fenian cycle may reflect the political and social conditions in Ireland during the A.D. 200's.

The most famous story in the Fenian cycle is called "The Pursuit of Diarmuid and Grainne." In this story, Finn was to marry Grainne, the daughter of an Irish king. However, she fell in love with Diarmuid, Finn's friend and nephew, and persuaded Diarmuid to elope with her. Finn and his warriors pursued the lovers. Much of the story concerns the adventures of Diarmuid and Grainne as they fled Finn.

Finally, Finn caught Diarmuid and Grainne and indirectly caused the death of Diarmuid. At first, Grainne hated Finn, but he courted her until she became his wife. See **Finn MacCool.**

Welsh myths. Two races of divinities appear in Welsh mythology—the Children of Don and the Children of Llyr. Both races partly resemble the Tuatha De Danann in Irish mythology, possibly because many Irish Celts migrated to Britain and brought their mythology with them.

The most famous Welsh myths concern King Arthur and his knights. The mythical King Arthur was probably based on a powerful Celtic chief who lived in Wales during the A.D. 500's. Some stories about Arthur and his knights can be traced to such early Welsh literature as the "Four Branches of the Mabinogi." One of these stories tells of the knights' search for the Holy Grail, the cup Christ used at the Last Supper. Some scholars say the Christian myth of the Holy Grail originated in this story.

The Celtic god Cernunnos protected horned animals. He is shown wearing horns. He holds a collar, representing cosmic truth, and a snake, symbolizing prosperity and good fortune.

Teutonic mythology

Teutonic mythology consists of the myths of Scandinavia and Germany. It is sometimes called *Norse* mythology, after the Norsemen who lived in Scandinavia during the Middle Ages. The basic sources for Teutonic mythology consist of two works, called *Eddas.* They were oral poems that were written down in the 1200's (see **Edda**). Other information on Teutonic mythology comes from legends about specific families and heroes and from German literary and historical works of the Middle Ages.

The creation of life. According to the Eddas, two places existed before the creation of life—Muspellsheim, a land of fire, and Niflheim, a land of ice and mist. Between them lay Ginnungagap, a great emptiness where heat and ice met. Out of this emptiness came Ymir, a young giant and the first living thing. A second creature soon appeared, a cow named Auđumla. Ymir lived on Auđumla's milk. As Ymir matured, he gave birth to three beings. He bore them from his armpits and from one leg. The first divine family was thus born.

Meanwhile, a second giant, Buri, was frozen in the ice of Niflheim. Auđumla licked the ice off his body, freeing him. Buri created a son named Bor, who married the giantess Bestla. They had three sons—Odin, Ve, and Vili. The sons founded the first race of gods.

The construction of the world. After Odin became an adult, he led his brothers in an attack on the giant Ymir and killed him. Odin then became supreme ruler of the world. The gods defeated the giants in battle, but the giants planned revenge on their conquerors.

Odin and his brothers constructed the world from Ymir's body. His blood became the oceans, his ribs the mountains, and his flesh the earth. The gods created the first man from an ash tree and the first woman from an elm tree. They also constructed Asgard, which became their heavenly home. Valhalla, a great hall in Asgard, was the home of warriors killed in battle.

Many divinities lived in Asgard. These divinities were

called the *Aesir,* just as the leading Greek gods and goddesses were called the Olympians. The ruler of Asgard was Odin. Thor, Odin's oldest son, was god of thunder and lightning. Balder, another of Odin's sons, was god of goodness and harmony. Other divinities included Bragi, the god of poetry, and Loki, the evil son of a giant. The most important goddesses included Frigg, Odin's wife; Freyja, goddess of love and beauty; and Hel, goddess of the underworld.

A giant ash tree known as Yggdrasil supported all creation. In most accounts of Yggdrasil, the tree had three roots. One root reached into Niflheim. Another grew to Asgard. The third extended to Jotunheim, the land of the giants. Three sisters called Norns lived around the base of the tree. They controlled the past, present, and future. A giant serpent called Nidoggr lived near the root in Niflheim. The serpent was loyal to the race of giants defeated by Odin. It continually gnawed at the root to bring the tree down, and the gods with it.

Teutonic heroes. Sigurd the Dragon Slayer probably ranks as the most important hero in Teutonic mythology. He appears in a Scandinavian version of German myths about a royal family called the Volsungs. Sigurd became the model for the mythical German hero Siegfried, who appears in the *Nibelungenlied,* a famous German epic of the Middle Ages. Other heroes in Teutonic mythology include Starkad, who was a mortal friend of Odin's, and the Danish warrior Hadding. See **Nibelungenlied.**

The end of the world. Unlike many other major Western mythologies, Teutonic mythology includes an *eschatology* (an account of the end of the world). According to Teutonic mythology, there will be a great battle called *Ragnarok.* This battle will be fought between the giants, led by Loki, and the gods and goddesses living in Asgard. All the gods, goddesses, and giants in the battle will be killed, and the earth will be destroyed by fire. After the battle, Balder will be reborn. With several sons of dead gods, he will form a new race of divinities. The human race will also be re-created. During Ragnarok, a man and woman will take refuge in a forest and sleep through the battle. After the earth again becomes fertile, the couple will awake and begin the new race of human beings. The new world, cleansed of evil and treachery, will endure forever.

American Indian mythology

At the time that Christopher Columbus landed in the New World, Indians lived throughout North and South America. The Indians had many different ways of life and many distinct mythologies. But all the mythologies shared several features. Most Indians believed in the supernatural, including a great variety of gods. The Indians created elaborate religious ceremonies through which they hoped to gain supernatural powers to aid them in searching for food or in fighting enemies. Indian mythologies have many heroes who gave man his first laws and established basic social institutions. Many mythologies describe the end of the world through some great disaster, such as a fire or flood. For more information on the religion of the Indians, see **Indian, American** (Religion).

The Aztec Indians of central Mexico developed one of the most interesting Indian mythologies. The Aztec established a highly advanced civilization that lasted from the A.D. 1300's to 1521. In 1521, Spanish troops led by Hernando Cortés conquered the Aztec. Advanced cultures, such as those of the Toltec and Maya, had existed in Mexico before the Aztec came to power. The Aztec borrowed many of their divinities from these earlier Indian cultures. In addition, the Aztec conquered many of the neighboring Indian peoples. As these peoples became part of the Aztec empire, many of their divinities became part of the Aztec mythology. The Aztec thus developed an extremely complicated mythology, composed of gods of earlier Indian civilizations, their own gods, and gods of the peoples they had conquered.

The Aztec believed the universe had passed through four ages called *suns* and that they were living in the fifth sun. The gods had ended each previous sun with a worldwide disaster and then created a new world. At the end of the first sun, the world was destroyed by jaguars. At the end of the second sun, a hurricane de-

Illustration from the *Codex Borbonicus;* Library of the National Assembly, Palais Bourbon, Paris

The Aztec god Quetzalcóatl was a god of the wind and the protector of the arts. His portrait shows how the Aztec clothed their divinities in colorful and complicated religious symbols.

stroyed the earth. At the end of the third sun, fire rained from the sky and destroyed the world. At the end of the fourth sun, the world ended with a flood. The Aztec believed they were living in the fifth sun and that the world would end with an earthquake.

The chief Aztec divinity was probably the war god, Huitzilopochtli. The Aztec worshiped Tezcatlipoca, a sun god, under four forms, each identified with a specific color and direction. Almost every Indian civilization in Mexico worshiped the god Quetzalcóatl. The Aztec associated him with the arts. Tláloc, the rain god, was probably the oldest god in Aztec mythology. His wife or sister, Chalchiuhtlicue, was goddess of running water. She protected newborn children, marriage, and innocent love. Tlazoltéotl was goddess of pleasure and guilty love. Farming formed the basis of the Aztec economy, and so the people worshiped many agricultural divinities. The most important of these divinities included Centéotl, the maize god; Chicomecóatl, the goddess of agricultural abundance; and Xipe Totec, the god of vegetation.

In Aztec mythology, souls of the dead lived in separate places, depending on how death occurred. For example, a place called Tonatiuhichan was reserved for warriors and victims of religious sacrifices. Other places were reserved for persons who had drowned or for women who had died in childbirth. Most souls passed to Mictlan, an underworld ruled by Mictlantecuhtli and his wife, Mictlancíhuatl.

Human sacrifice played an important role in Aztec religion. The Aztec held great ceremonies and festivals during which they offered human hearts to Huitzilopochtli and the other major divinities. The Aztec slashed open the chests of their sacrificial victims and tore out their hearts. Most of the victims were prisoners of war. The Aztec considered the victims as representatives of the gods themselves. During the period up to their deaths, some victims were dressed in rich clothing, given many servants, and treated with great honor. The Aztec believed that the souls of the sacrificial victims flew immediately to Tonatiuhichan and lived there forever in happiness.

How myths began

For at least 2,000 years, scholars have speculated about how myths began. Some believe myths began as historical events that became distorted with the passage of time. Others think myths resulted from an attempt to explain natural occurrences that people could not understand. Scholars have also developed other theories of how myths began. None of these theories answers all the questions about myths, but each contributes to an understanding of the subject.

Euhemerus's theory. Euhemerus, a Greek scholar who lived during the late 300's and early 200's B.C., developed one of the oldest known theories about the origin of myths. He was one of the first scholars to suggest that all myths are based on historical facts. Euhemerus believed that scholars had to strip away the supernatural elements in a myth to reach these facts. For example, he felt that Zeus was probably modeled on an early king of Crete who had such great power that he inspired many supernatural tales.

However, Euhemerus's theory has one basic weakness. In most cases, modern scholars lack enough historical evidence to determine whether a mythical figure ever existed.

Müller's theory. Friedrich Max Müller was a German-born British language scholar of the late 1800's. He suggested that all gods and mythical heroes were representations of nature, especially the sun.

To Müller, nearly all major divinities and heroes were originally a symbol for the sun in one of its phases. Thus, the birth of a hero stood for the dawn. The hero's triumph over obstacles stood for the sun at noon, its highest point. The hero's decline and death expressed the sunset.

Müller decided that by the time such basic texts as the *Theogony* and the *Rig-Veda* appeared, the symbolic purpose of the gods and heroes had long been forgotten. Instead, people had come to believe in the divinities and heroes themselves. For example, the ancient Greeks believed that the sun god Helios drove his flaming chariot, the sun, across the sky every day. This belief began in an earlier attempt to express symbolically how each day the sun rose in the east and set in the west.

Today, few scholars take Müller's main theories seriously. However, he and his followers did influence most later theories about the origin of myths.

Tylor's theory. Sir Edward Burnett Tylor was an English anthropologist of the 1800's. He believed that myths began through people's efforts to account for unexplainable occurrences in dreams. According to Tylor, the first idea about the supernatural was the belief that a soul lived within the human body. While the body slept, the soul could wander freely and have many adventures. These adventures appeared to people in dreams. People then came to believe that animals had souls. Finally, they decided that everything in nature had a soul. They could then explain, according to Tylor, such natural events as the eruption of a volcano. Gradually, people came to believe that the souls controlling natural occurrences could answer prayers for protection or special favors. The idea that all things in nature have souls is called *animism* (see **Animism**). Tylor considered animism the first step in the development of human thought—and the basis of myths.

Frazer's theory. Sir James George Frazer was a Scottish anthropologist of the late 1800's and early 1900's. He believed that myths began in the great cycle of nature—birth, growth, decay, death, and rebirth.

Frazer's theory developed from his attempt to explain an ancient Italian *ritual* (ceremony) conducted at Nemi, near Rome. At Nemi, there was a sacred grove of trees. In the middle of the grove grew a huge oak tree associated with the god Jupiter. A priest presided over the grove and the oak tree. Frazer's curiosity and interest were aroused by the way priests were replaced. To be-

Venus, Mother of Aeneas, Presenting Him with Arms Forged by Vulcan (1635), an oil painting on canvas by Nicolas Poussin; Art Gallery of Ontario, Toronto, gift of the Reuben Wells Leonard estate, 1948

The Trojan warrior Aeneas receives weapons from his mother, Venus, to use in the Trojan War. Aeneas survived Troy's defeat by the Greeks and founded a colony in Italy. The ancient Romans traced their origin as a nation to Aeneas. According to the ancient Greek scholar Euhemerus, all myths are based on historical events, such as the Trojan War.

come the priest, a man had to kill the current priest with a branch of mistletoe taken from the top of the oak. If the man succeeded, he proved that he had more vigor than the presiding priest and thus had earned the position.

Frazer's study of the Nemi ritual developed into one of the most ambitious anthropological works ever attempted, *The Golden Bough* (12 volumes, 1890-1915). In writing this work, Frazer made a broad study of ancient and primitive mythologies and religions. He concluded that the priests at Nemi were killed as a sacrifice. The ancient Italians believed that when a priest began to lose his vigor, so did Jupiter. As Jupiter became less vigorous, so did the world. For example, winters became longer and the land became less fertile. To keep the world healthy, the priest, representing Jupiter, had to be killed and then reborn in the form of the more vigorous slayer.

Frazer wrote that societies throughout the world sacrificed symbols of their gods to keep these gods—and thus the world—from decaying and dying. According to Frazer, this theme of the dying and reborn god appears in almost every ancient mythology, either directly or symbolically. Frazer therefore concluded that myths originated from the natural cycle of birth, growth, decay, death, and—most important—rebirth.

The ritualist theory. Closely related to Frazer's ideas were those of the so-called *ritualists.* The ritualists believed that myths derive from rituals or ceremonies. The first scholar to develop this theory was Jane Ellen Harrison, a British classicist of the late 1800's and early 1900's and a colleague of Frazer's. Harrison argued that people create myths in order to justify already established magical or religious rituals. Harrison believed that many myths become the scripts for such rituals.

Fitzroy Richard Somerset, known as Lord Raglan, an English nobleman of the early 1900's, was perhaps the most influential of the ritualists. His best-known theory concerns the life of the typical hero figure. Raglan pointed out that all heroes or hero-gods share a number of common characteristics. He suggested a "ritualistic formula" that included an unusual or difficult conception, a youthful exile, a triumphant return to claim a rightful inheritance, a successful reign followed by a final downfall, and a mysterious death in which the hero's mortal remains disappear. Thus, Raglan regarded such figures as Moses, King Arthur, Robin Hood, and Leif Ericson as fictitious.

Today, few mythologists seriously consider this theory. It is now generally believed that myths and rituals are equally ancient and that it is impossible to prove that one is older than the other. Other modern scholars have disproved Raglan's assumption that all heroes are fictitious. However, by emphasizing the sacred contexts in which many myths are told, the ritualists broadened the scope of mythology and influenced other scholars.

Malinowski's theory. Bronislaw Malinowski was a Polish-born British anthropologist of the early 1900's. He disagreed with Tylor that myths began as prescientific attempts to explain dreams and natural occurrences. Instead, Malinowski emphasized the psychological conditions that lead people to create myths.

According to Malinowski, all people recognize that a frontier exists between what people can and cannot explain logically. Malinowski said people create myths when they reach this frontier. For example, early human beings lacked the scientific knowledge to explain thunder logically, and so they decided it was caused by a

god using a hammer. Malinowski believed that people had to create such myths in order to relieve the tension brought on by their not knowing why something happens.

Jensen's theory. Adolf E. Jensen, a German anthropologist of the early and middle 1900's, was influenced by the ideas of Frazer and the ritualists. While conducting field research among an Indonesian tribe called the Wemale, Jensen discovered a myth-ritual associated with the beautiful and virtuous goddess called Hainuwele. Falsely accused of all kinds of crimes, Hainuwele was torn to pieces by an angry mob. Later, her body parts were buried around the edge of the village. From each part sprouted one of the major Wemale food plants. In the Wemale dialect, a figure such as Hainuwele is called a *dema*.

Jensen suggested that similar *dema deities* exist in the mythologies of a variety of primitive cultures in the Pacific Islands, Africa, and North and South America. Other modern scholars have discovered dema deities in several Near Eastern and Indo-European mythologies. Examples include the Babylonian goddess Tiamat, from whose corpse the sky god Marduk formed the world, and the Norse giant Ymir, whose dismembered remains served a similar purpose in Teutonic mythology. Although dema deities are probably not universal, they are extremely widespread and may play an important role in most of the world's mythologies.

Lévi-Strauss's theory. Many modern scholars have applied the methods developed by linguists to the study of mythology. These scholars believe that a set of interpreted myths serves as a form of language. People use myths to express—for the most part unconsciously—their deeply held ideas about themselves and their relationship to the world around them. This approach to mythology is often referred to as *structuralism*.

Claude Lévi-Strauss, a modern French anthropologist, is the best-known supporter of structuralism. According to Lévi-Strauss, a myth's basic purpose is to resolve an otherwise unresolvable contradiction. Illustrating this theory is his interpretation of the Oedipus myth. In this ancient Greek story, Oedipus, the king of the city of Thebes, unknowingly kills his father and marries his mother. When the truth is revealed to him, Oedipus leaves Thebes with his children and dies in exile.

In explaining the meaning of the Oedipus myth, Lévi-Strauss groups together episodes that share common characteristics. He also considers the whole story, not simply the part that Oedipus plays in it. In the story, Oedipus' great-grandfather, Cadmus, kills a dragon, and Oedipus himself kills a monster called the Sphinx. Lévi-Strauss suggests that both actions reflect people's triumph over the forces of nature, represented by the dragon and the Sphinx.

However, a contrasting theme also appears in the myth. The Greek word *Oedipus* means *swollen foot,* and Oedipus' father, Laius, and his grandfather, Labdacus, also had names that refer to difficulties in walking. The choice of names reflects the extent to which humanity can never escape nature. According to Lévi-Strauss, such themes must be fully explored before one can understand the "deep structure" of the Oedipus myth. Lévi-Strauss believes such corresponding deep structures exist in all myths.

Some scholars argue that Lévi-Strauss's theories are too subjective. Other critics claim that his structural models are too far removed from the actual mythological texts to say anything meaningful about them. Nevertheless, the structuralist approach has had a profound impact on modern mythological studies. The idea that myths and other traditional narratives reflect a deep-seated model of some sort is accepted by most anthropologists and by most scholars who study myths, legends, and folklore.

What mythology tells us about people

Many social scientists have developed theories telling how we can learn about people from the myths they tell. Some of these theories stress the role of myths in understanding society as a whole. Other theories emphasize the place of mythology in understanding why an individual acts in a certain way.

Mythology and society. During the late 1800's and early 1900's, the French sociologist Émile Durkheim developed several important theories on what he felt was the real meaning of myths. Durkheim believed that every society establishes certain social institutions and values, which are reflected in the society's religion. Therefore, according to Durkheim, most of a society's gods, heroes, and myths are really *collective representations* of the institutions and values of that society or of important parts within it. These representations determine how the individuals in the society think and act. By examining a society's myths, Durkheim believed, a sociologist can discover its social institutions and values.

Georges Dumézil, a modern French scholar, was influenced by Durkheim's ideas in the study of Indo-European mythology. According to Dumézil, the principal Indo-European divinities were collective representations of the *caste* (class) system common to several ancient Indo-European peoples. In ancient India the gods Mitra and Varuna represented the Brahman castes—the highest castes in Hindu society, made up of priests and scholars. The god Indra represented the warrior castes, which ranked below the Brahmans. The Ashvin twins represented still lower castes—farmers and herders. The relation between these divinities reveals what the Hindus considered proper conduct among the castes.

One ancient Indian myth tells that Indra killed a monster that threatened the peace and security of the gods. But the monster happened to be the chaplain of the gods and therefore a divine Brahman. As a result, Indra felt he had committed a great sin because he had killed a Brahman. This myth illustrates the ancient Indian belief that under no circumstances should a member of one caste harm a member of a higher caste.

Mythology and the individual. In the early 1900's, the Swiss psychoanalyst Carl Jung developed a contro-

versial theory about how myths reflect the attitudes and behavior of individuals. Jung suggested that everyone has a *personal* and a *collective* unconscious. An individual's personal unconscious is formed by the person's experiences in the world as filtered through the senses. An individual's collective unconscious is inherited and shared by all humankind.

Jung believed that the collective unconscious is organized into basic patterns and symbols, which he called *archetypes*. Myths represent one kind of archetype. Other kinds include fairy tales, folk sagas, and works of art. Jung believed that all mythologies have certain features in common. These features include characters, such as gods and heroes, and themes, such as love or revenge. Other features include places, such as the home of the gods or the underworld, and plots, such as a battle between generations for control of a throne. Jung suggested that archetypes date back to the earliest days of humankind. By studying myths and other archetypes, Jung believed, scholars could trace the psychological development of particular cultures as well as of all humankind. C. Scott Littleton
